Publication numbering

As from 1 January 1997 all IEC publications are issued with a designation in the 60000 series. For example, IEC 34-1 is now referred to as IEC 60034-1.

Consolidated editions

The IEC is now publishing consolidated versions of its publications. For example, edition numbers 1.0, 1.1 and 1.2 refer, respectively, to the base publication, the base publication incorporating amendment 1 and the base publication incorporating amendments 1 and 2.

Further information on IEC publications

The technical content of IEC publications is kept under constant review by the IEC, thus ensuring that the content reflects current technology. Information relating to this publication, including its validity, is available in the IEC Catalogue of publications (see below) in addition to new editions, amendments and corrigenda. Information on the subjects under consideration and work in progress undertaken by the technical committee which has prepared this publication, as well as the list of publications issued, is also available from the following:

- **IEC Web Site (www.iec.ch)**

- **Catalogue of IEC publications**

    The on-line catalogue on the IEC web site (www.iec.ch/catlg-e.htm) enables you to search by a variety of criteria including text searches, technical committees and date of publication. On-line information is also available on recently issued publications, withdrawn and replaced publications, as well as corrigenda.

- **IEC Just Published**

    This summary of recently issued publications (www.iec.ch/JP.htm) is also available by email. Please contact the Customer Service Centre (see below) for further information.

CABLED DISTRIBUTION SYSTEMS FOR TELEVISION AND SOUND SIGNALS –

Part 9: Interfaces of cabled distribution systems for digitally modulated signals

FOREWORD

1) The IEC (International Electrotechnical Commission) is a worldwide organization for standardization comprising all national electrotechnical committees (IEC National Committees). The object of the IEC is to promote international co-operation on all questions concerning standardization in the electrical and electronic fields. To this end and in addition to other activities, the IEC publishes International Standards. Their preparation is entrusted to technical committees; any IEC National Committee interested in the subject dealt with may participate in this preparatory work. International, governmental and non-governmental organizations liaising with the IEC also participate in this preparation. The IEC collaborates closely with the International Organization for Standardization (ISO) in accordance with conditions determined by agreement between the two organizations.

2) The formal decisions or agreements of the IEC on technical matters express, as nearly as possible, an international consensus of opinion on the relevant subjects since each technical committee has representation from all interested National Committees.

3) The documents produced have the form of recommendations for international use and are published in the form of standards, technical specifications, technical reports or guides and they are accepted by the National Committees in that sense.

4) In order to promote international unification, IEC National Committees undertake to apply IEC International Standards transparently to the maximum extent possible in their national and regional standards. Any divergence between the IEC Standard and the corresponding national or regional standard shall be clearly indicated in the latter.

5) The IEC provides no marking procedure to indicate its approval and cannot be rendered responsible for any equipment declared to be in conformity with one of its standards.

6) Attention is drawn to the possibility that some of the elements of this International Standard may be the subject of patent rights. The IEC shall not be held responsible for identifying any or all such patent rights.

International Standard IEC 60728-9 has been prepared by subcommittee 100D: Cabled distribution systems, of IEC technical committee 100: Audio, video and multimedia systems and equipment.

The text of this standard is based on the following documents:

FDIS	Report on voting
100/158/FDIS	100/180/RVD

Full information on the voting for the approval of this standard can be found in the report on voting indicated in the above table.

This publication has been drafted in accordance with the ISO/IEC Directives, Part 3.

Annexes A and B form an integral part of this standard.

Annexes C, D, E and F are for information only.

The committee has decided that the contents of this publication will remain unchanged until 2006. At this date, the publication will be

- reconfirmed;
- withdrawn;
- replaced by a revised edition, or
- amended.

A bilingual version of this standard may be issued at a later date.

INTRODUCTION

Standards of the IEC 60728 series deal with cable networks for television signals, sound signals and interactive services including equipment, systems and installations

– for headend reception, processing and distribution of television and sound signals and their associated data signals, and

– for processing, interfacing and transmitting all kinds of signals for interactive services using all applicable transmission media.

All kinds of networks like

– CATV-networks,

– MATV-networks and SMATV-networks,

– individual receiving networks

and all kinds of equipment, systems and installations installed in such networks, are within the scope of this series.

The extent of this standardization work goes from the antennas, special signal source inputs to the head-end, or other interface points to the network, up to the system outlet or the terminal input, where no system outlet exists.

The standardization of any user terminals (i.e. tuners, receivers, decoders, multimedia terminals, etc.) as well as of any coaxial and optical cables and accessories therefore is excluded.

CABLED DISTRIBUTION SYSTEMS FOR TELEVISION AND SOUND SIGNALS –

Part 9: Interfaces of cabled distribution systems for digitally modulated signals

1 Scope

This part of IEC 60728 describes physical interfaces for the interconnection of signal processing devices for professional CATV/SMATV headend equipment or for similar systems, such as in up-link stations. This standard, in particular, specifies the transfer of MPEG-2 data signals in the standardized transport layer format between devices of different signal processing functions.

RF interfaces and interfaces to telecom networks are not covered by this standard.

In addition references are made to all other parts of the IEC 60728 series and, in particular, for RF, video and audio interfaces, to IEC 60728-5.

For connections to telecom networks, special Data Communication Equipment (DCE) is necessary to adapt the serial or parallel interfaces specified in this document to the bitrates and transmission formats of the public Plesiochronic Digital Hierarchy (PDH) networks. Other emerging technologies such as Connectionless Broadband Data Services (CBDS), Synchronous Digital Hierarchy (SDH), Asynchronous Transfer Mode (ATM), etc. can be used for transmitting MPEG-2 Transport Streams (TS) between remote locations. ATM is particularly suitable for providing bandwidth on demand and it allows for high data rates.

2 Normative references

The following normative documents contain provisions which, through reference in this text, constitute provisions of this part of IEC 60728. For dated references, subsequent amendments to, or revisions of, any of these publications do not apply. However, parties to agreements based on this part of IEC 60728 are encouraged to investigate the possibility of applying the most recent editions of the normative documents indicated below. For undated references, the latest edition of the normative document referred to applies. Members of IEC and ISO maintain registers of currently valid International Standards.

3   Terms, definitions and abbreviations

3.1   Terms and definitions

For the purposes of this part of IEC 60728, the following definitions apply.

3.1.1
head-end
equipment connected between receiving antennas or other signal sources and the remainder of the cable distribution system to process the signals to be distributed

NOTE   The head-end may, for example, comprise antenna amplifiers, frequency converters, combiners, selectors and generators.

3.1.2
Satellite Master Antenna Television system (SMATV)
system designed to provide sound and television signals to the households of a building or group of buildings

NOTE   Two system configurations are defined in ETS 300 473 as follows:

- SMATV system A, based on transparent transmodulation of QPSK satellite signals into QAM signals to be distributed to the user;
- SMATV system B, based on direct distribution of QPSK signals to the user, with two options:
    - SMATV-IF distribution in the satellite IF band (above 950 MHz);
    - SMATV-S distribution in the VHF/UHF band, for example in the extended S-band (230-470 MHz).

---

[1])   To be published.

3.1.3
biphase mark
line code which ensures DC balance, easy clock recovery and polarity freedom

3.1.4
transport stream
includes one or more programs with one or more independent time bases into a single stream. The transport stream is designed for use in environments where errors are likely, such as storage or transmission in lossy or noisy media

3.1.5
transport packet
packetized element of the transport stream. The packets are either 188 bytes or, in the case where Reed Solomon FEC is used, 204 bytes in length

3.1.6
DVALID
signal which indicates in the 204-byte mode of a Transport Stream that the empty space is filled with dummy bytes

3.1.7
PSYNC
flag which indicates the beginning of a packet

4   Interfaces for MPEG-2 data signals

4.1   Introduction

This subclause describes possible interfaces for devices transmitting or receiving MPEG-2 data as transport packets, such as QPSK demodulators, QAM modulators, multiplexers, demultiplexers, or telecom network adapters.

This specification is similar to ETS 300429 and ETS 300421.

NOTE   Both standards describe a first functional block representing the MPEG2 source coding and multiplexing as standardized in ISO/IEC 13818-1, a second functional block representing the channel adaptation, whereas an interface in between shall be based on MPEG2 transport stream specification according to ISO/IEC 13818-1.

The function of the channel modulator/demodulator is to adapt the signal to the characteristics of the transmission channel: satellite, terrestrial or cable as specified in the DVB base line documents.

Also the case where data signals are transmitted to or from a headend via a telecom network, or if a headend serves to insert data signals into such networks, is considered to be covered by the generic channel modulator/demodulator functional block. The interface parameters valid for this network have to be met. For the latter, reference is made to ITU-T G.703 for Plesiochronic Digital Hierarchy (PDH) networks.

4.1.1   Application requirements

In order to avoid any unnecessary processing at the transmitting or receiving station of an interface in certain applications, it is considered an application requirement that the interface supports 204-byte packet length in such cases, in addition to or instead of the 188-byte packet length specified in ISO/IEC 13818-1. These two cases are identified in the protocol diagrams of figures 1 and 2, where also the scope of this specification is delineated. The relevant associated packet structures are illustrated in figures 3 and 4.
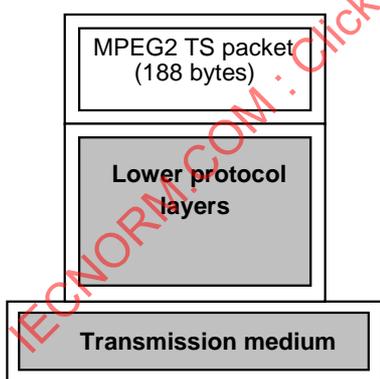

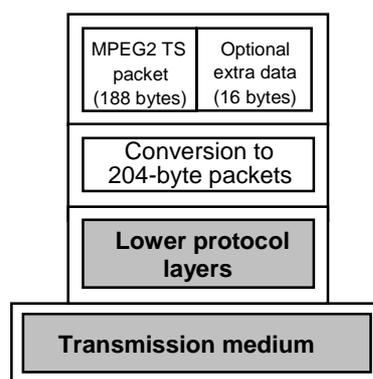

Figure 1 – Protocol stack for 188-byte packets　　**Figure 2 – Protocol stack for 204-byte packets**

NOTE   Shaded areas identify the scope of this standard.

IEC 2183/2000

Figure 3 – Packet structure of 188-byte packet

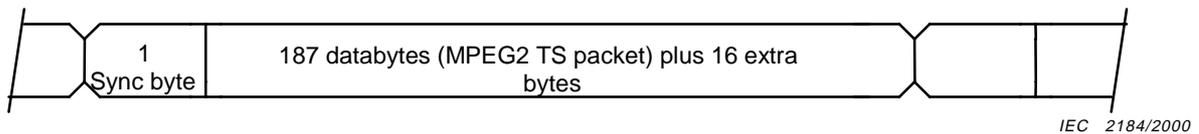

IEC 2184/2000

Figure 4 – Packet structure of 204-byte packet

4.1.2   Interfaces

Three interfaces and two serial transmission media are specified as follows:

- SPI   (Synchronous Parallel Interface);
- SSI-C   (Synchronous Serial Interface on coaxial cable);
- SSI-O   (Synchronous Serial Interface on optical fibre);
- ASI-C   (Asynchronous Serial Interface on coaxial cable);
- ASI-O   (Asynchronous Serial Interface on optical fibre).

Each of these interfaces feature a BER such that FEC is not required for reliable data transport.

The synchronous parallel interface is specified to cover short or medium distances, i.e. for devices arranged near each other. Subclause 4.2 describes the definitions for such a parallel interface derived from ITU-R Recommendation BT.656-4. Flags are provided to distinguish 188-byte packets from 204-byte packets and to signal the existence of valid RS bytes. Note that the interface, as such, is transparent to the RS bytes.

The synchronous serial interface (SSI) which can be seen as an extension of the parallel interface, is briefly introduced in 4.3 and described in detail in annexes A and D. The packet length and the existence of valid RS bytes are conveyed through suitable coding mechanisms.

Subclause 4.4 introduces the Asynchronous Serial Interface (ASI). Details of the ASI are provided in annexes B and E. The ASI is configurable to either convey 188-byte packets (which is mandatory) or optionally 204-byte packets.

4.1.3   Packet length and contents

Each of the interface specifications can be used to convey either 188-byte packets or 204-byte packets in order to enable selection of the appropriate interface characteristics dependent on the kind of equipment to be interconnected. Mandatory and optional packet sizes are specified in table 1.

Table 1 – Mandatory and optional packet lengths

Interface		Data packet carrying capability		
		188 bytes	204 bytes (with 16 dummy bytes)	204 bytes (with 16 RS bytes)
SPI	transmitter	O	M	O
	receiver	M	M	M
SSI	transmitter	O	M	O
	receiver	M	M	M
ASI	transmitter	M	O	O
	receiver	M	O	O
M = mandatory O = optional				

In case the data stream is packetized in 188-byte packets and the interface is configured to convey 204-byte packets, the extra packet length can be used for additional data. The contents of the 16 bytes in this extra packet length are not specified in this standard. One application could be the transmission of 16 RS bytes associated with the preceding transport package.

4.1.4 Compliance

For an equipment to be compliant to this standard it is sufficient for the equipment to show at least one instance of at least one of the interface specifications as described in 4.1.2 and specified in detail in subsequent subclauses of this standard, while at least the mandatory packet sizes as indicated in 4.1.3 shall be supported.

4.1.5 System integration

The interfaces specified in this standard define physical connections between various pieces of equipment. It is important to notice that various parameters which are important for interoperation are not specified in this standard. This is intentional as it leaves maximum implementation flexibility for different applications. In order to facilitate system integration, equipment suppliers shall provide the following information about the characteristics of the interfaces in their equipment:

- interface type (SPI, SSI-C, SSI-O, ASI-C, ASI-O);
- supported packet length (188 bytes, 204 bytes, both);
- maximum input jitter (jitter measured as specified in ISO/IEC 13818-9);
- output jitter (jitter measured as specified in ISO/IEC 13818-9);
- minimum input data rate (rate measured as specified in ISO/IEC 13818-1);
- maximum input data rate (rate measured as specified in ISO/IEC 13818-1).

Some of these parameters may not be applicable to certain types of equipment. If all relevant parameters are provided by equipment suppliers, the proper functioning of the complete system can be ensured.

4.2 Synchronous parallel interface (SPI)

This subclause describes an interface for a system for parallel transmission of variable data rates. The data transfer is synchronized to the byte clock of the data stream, which is the MPEG Transport Stream. Transmission links use LVDS technology [2][1] and 25-pin connections.

_____
[1] Figures in brackets refer to items in the bibliography.

IEC 2185/2000
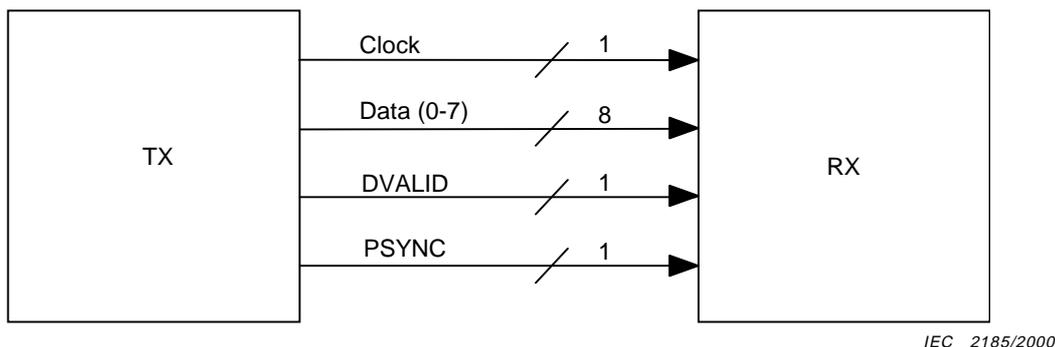

Figure 5 – System for parallel transmission

The data to be transmitted are MPEG-2 Transport Packets with 188 or 204 bytes. In the case of the 204-byte packet format, packets may contain a 16-byte "empty space"; a DVALID signal serves to identify these dummy bytes. A PSYNC flag labels the beginning of a packet. The data are synchronized to the clock depending on the transmission rate.

Equipment which implements the parallel interface shall support the three transmission formats as shown in figures 6, 7 and 8.

4.2.1   Signal format

The clock, data, and synchronization signals shall be transmitted in parallel: 8 data bits together with one (MPEG-2) PSYNC signal and a DVALID signal which indicates in the 204-byte mode that the empty space is filled with dummy bytes. All signals are synchronous to the clock signal. The signals are coded in NRZ form.

IEC 2186/2000

Figure 6 – Transmission format with 188-byte packets

IEC 2187/2000
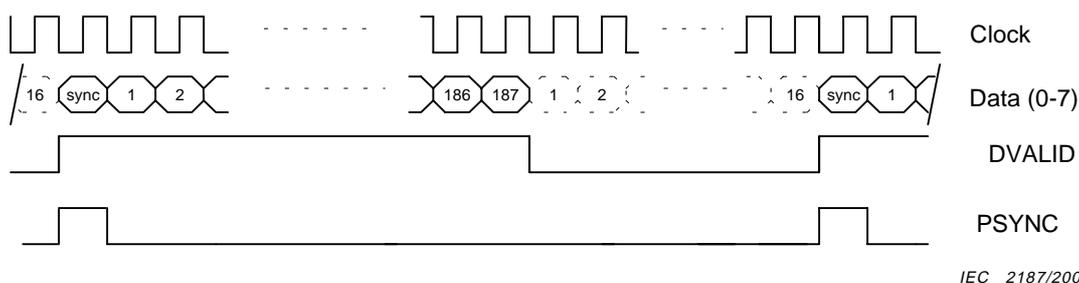

Figure 7 – Transmission format with 204-byte packets
(188 data bytes and 16 dummy bytes)
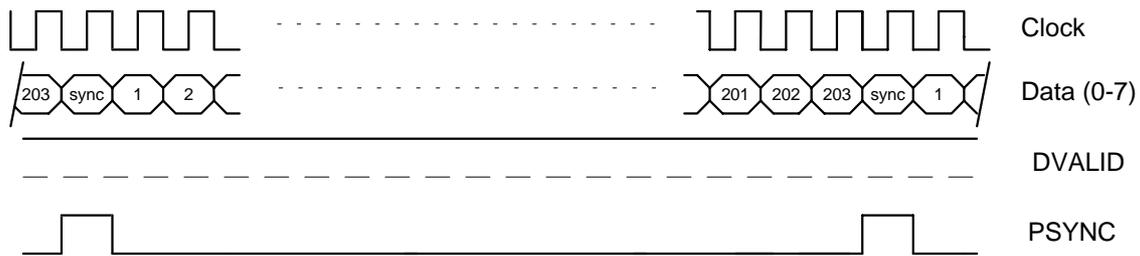

Figure 8 – Transmission format with RS-coded packets (204 bytes) as specified in ETS 300 421 (188 data bytes and 16 valid extra bytes)
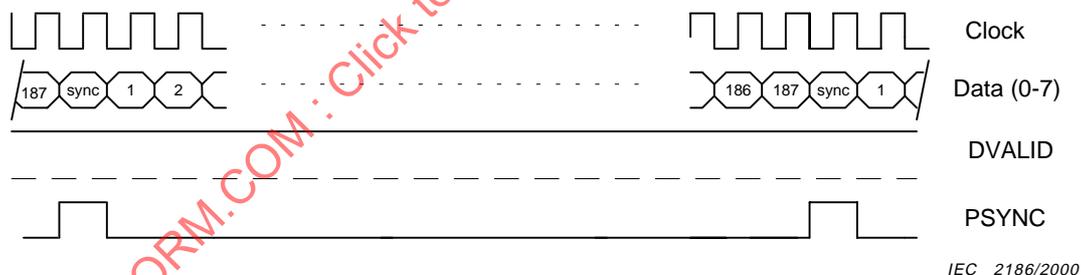

Data (0-7):   Transport packet data word (8 bit: Data 0 to Data 7). Data 7 is the Most Significant Bit (MSB).

DVALID: active logic "1". Indicates valid data at the interface. It is constantly high in the 188-byte mode. In the 204-byte mode a low logical state indicates not to check the extra (dummy) bytes.

PSYNC: active logic "1". Indicates the beginning of a Transport Packet by signalling the sync byte.

4.2.2   Clock signal

The clock is a square wave signal where the 0-1 transition represents the data transfer time. The clock frequency f_p depends on the transmission rate.

- The Transport Packets are transmitted without insertion of additional bytes for RS coding or padding (packet length 188 bytes):

$$f_p = f_u / 8$$

- The Transport Packets are transmitted with insertion of additional bytes for RS coding or padding (packet length 204 bytes):

$$f_p = (204 / 188) \times f_u / 8$$

The frequency f_u corresponds to the useful bitrate R_u of the MPEG-2 transport layer. The clock frequency f_p shall not exceed 13,5 MHz.

Timing reference for data and clock

Figure 9 – Clock to data timing (at source)

Clock period: $T = \dfrac{1}{f_\mathrm{p}}$

Clock pulse width: $t = \dfrac{T}{2} \pm \dfrac{T}{10}$

Data hold time: $t_\mathrm{d} = \dfrac{T}{2} \pm \dfrac{T}{10}$

4.2.3 Electrical characteristics of the interface

The interface employs 11 line drivers and 11 line receivers. Each line driver (source) has a balanced output and the corresponding line receiver (destination) a balanced input (see figure 10). The line driver and receiver shall be LVDS-compatible, i.e. they shall permit the use of LVDS for their drivers or receivers. All digital signal time intervals are measured between the half-amplitude points.

a) Logic convention

   The terminal A of the line driver is positive with respect to the terminal B for a binary 1 and negative for a binary 0 (see figure 10).
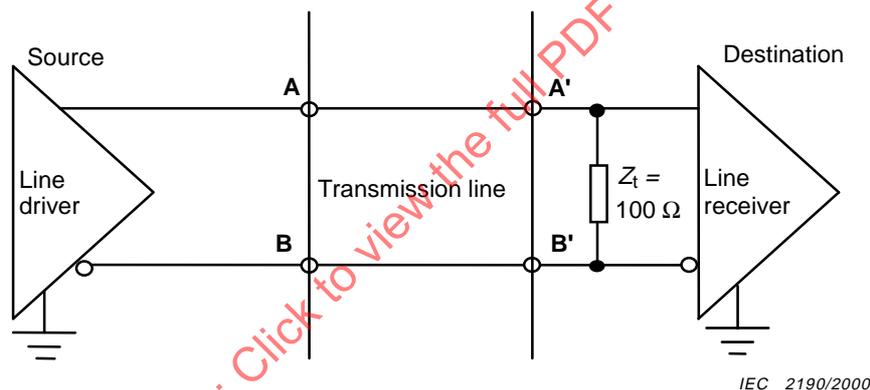

IEC 2190/2000

Figure 10 – Line-driver and line-receiver interconnection

b) Line-driver characteristics (source)

   Output impedance: 100 Ω maximum

   Common mode voltage: 1,125 V to 1,375 V

   Signal amplitude: 247 mV to 454 mV

   Rise and fall times: less than $T/7$, measured between the 20 % and 80 % amplitude points, with a 100 Ω resistive load. The difference between rise and fall times shall not exceed $T/20$.

c) Line receiver characteristics (destination)

   Input impedance: 90 Ω to 132 Ω

   Maximum input signal: 2,0 V peak-to-peak

   Minimum input signal: 100 mV peak-to-peak

However, the line receiver shall sense correctly the binary data when a random data signal produces the conditions represented by the eye diagram in figure 11 at the data detection point.

Maximum common mode signal: ±0,5 V, comprising interference in the range of 0 - 15 kHz (both terminals to ground).

Differential delay: Data shall be correctly sensed when the clock-to-data differential delay is in the range between $\pm T/3$ (see figure 11).
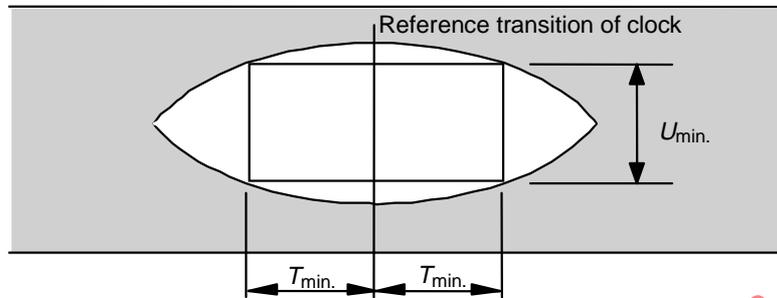

IEC 2191/2000

$T_{\min} = T / 3, \quad U_{\min} = 100$ mV

Figure 11 – Idealized eye diagram corresponding to the minimum input signal level

4.2.4 Mechanical details of the connector

The interface uses the 25-contact type D subminiature connector specified in ISO 2110 with the contact assignment shown in table 2.

Connectors are locked together with a screw lock, with male screws on the cable connector and female threaded posts on the equipment connector. The threads are of type UNC 4-40[3]. Cable connectors employ pin contacts and equipment connectors employ socket contacts. Shielding of the interconnecting cable and its connectors shall be employed.

Table 2 – Contact assignment of 25-contact type D subminiature connector (ISO 2110)

Pin	Signal line	Pin	Signal line
1	Clock A	14	Clock B
2	System gnd	15	System gnd
3	Data 7 A(MSB)	16	Data 7 B
4	Data 6 A	17	Data 6 B
5	Data 5 A	18	Data 5 B
6	Data 4 A	19	Data 4 B
7	Data 3 A	20	Data 3 B

9	Data 1 A	22	Data 1 B
10	Data 0 A	23	Data 0 B
11	DVALID A	24	DVALID B
12	PSYNC A	25	PSYNC B
13	Cable shield		

4.3   Synchronous Serial Interface (SSI)

The Synchronous Serial Interface (SSI) can be seen as the extension of the parallel interface by means of an adaptation of the parallel format. SSI is synchronous to the Transport Stream which is transmitted on the serial link.

A detailed specification of the SSI is provided in annex A and guidelines for its implementation are provided in annex D.

4.4   Asynchronous Serial Interface (ASI)

The Asynchronous Serial Interface (ASI) is a serial link operating at a fixed line clock rate.

A detailed specification of ASI is provided in annex B and guidelines for its implementation are provided in annex E.

4.5   3-Wire Interface (3WI)

The 3-Wire Interface (3WI) can be used for either a Single Program Transport Stream (SPTS) or a Multi-Program Transport Stream (MPTS).

A detailed specification of 3WI and guidelines for its implementation are provided in annex F.

Annex A
(normative)

Synchronous Serial Interface (SSI)

This annex describes a system for serial encoded transmission of different data rates, with a transmission rate equal to the data rate. It is based on a layered structure of MPEG-2 Transport Packets as a top layer (Layer-2), and a pair of bottom layers attached to physical and coding aspects (Layer-0 and Layer-1).

The SSI is based on a line rate directly locked to the transport rate. The SSI is functionally equivalent to the parallel interface, since the Transport Packets can either be transmitted contiguously or separated by 16 bytes reserved for dummy bytes or extra bytes. Because the link and the TS are synchronous, the bit justification operation is not needed. The system shall be designed to fulfil the high stability requirements of the modulator clocks, even when several links are cascaded.

As an example, consider a signal which passes through several re-broadcast steps, such as the one depicted in figure A.1. In this chain, the last clock (that of the QAM modulator) is slaved to the encoder/mux clock via four steps of clock regeneration circuits.
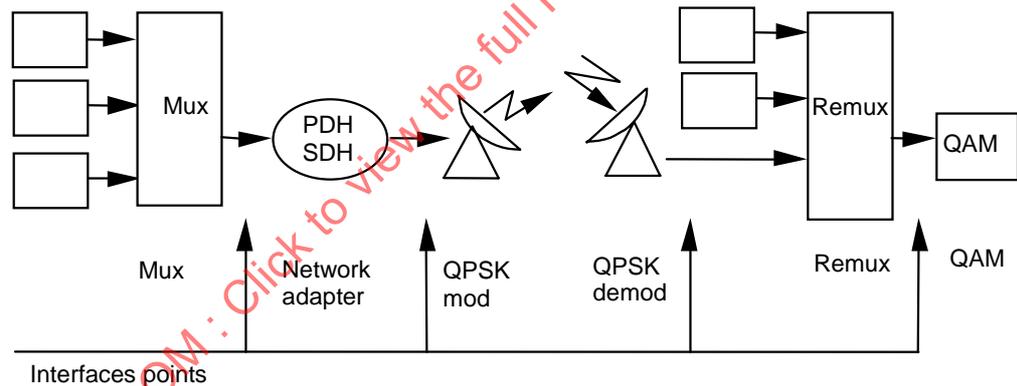

IEC   2192/2000

Figure A.1 – Example of cascaded interfaces

A.1   SSI transmission system overview

Figures A.2 and A.3 represent the primary components of this SSI method over copper coaxial cable and fibre-optic cable, respectively.
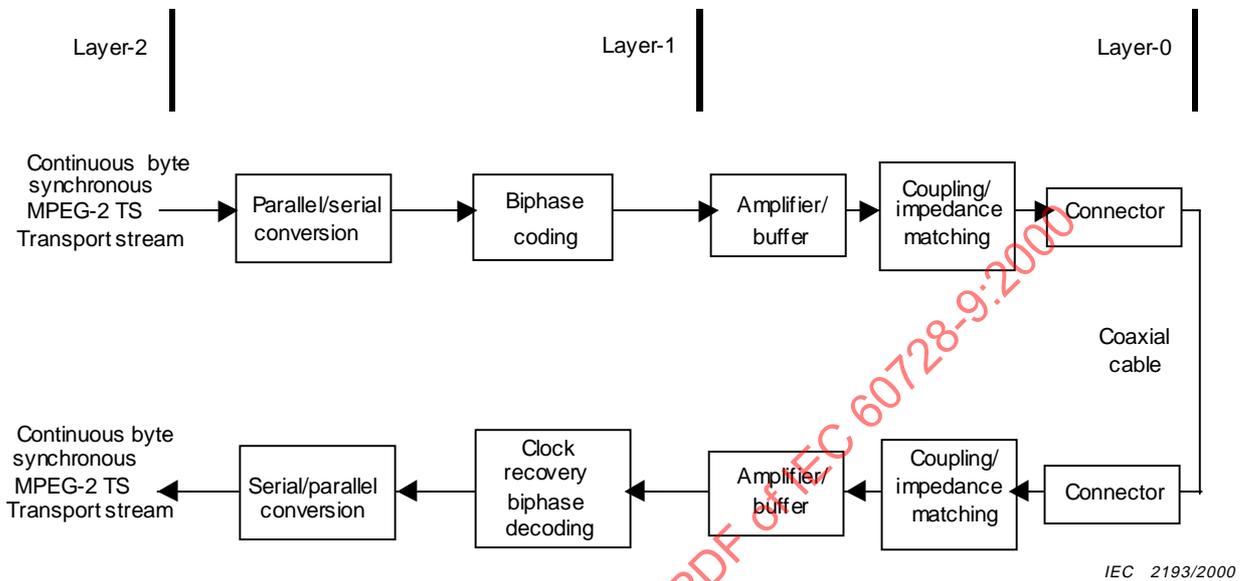

Figure A.2 – Coaxial cable-based synchronous serial transmission link (SSI type)

Figure A.3 – Fibre-optic-based synchronous serial transmission link (SSI type)

The main functions of the transmission system are described below.

a) Emission path

Data to be transmitted are presented in byte-synchronized form as MPEG-2 Transport Packets. The Transport Stream is then passed through a parallel-to-serial converter. The line data stream is locked to the TS data stream.

The serial signal is Biphase Mark-encoded.

In the case of a coaxial cable application, the resulting signal is typically passed to a buffer/driver circuit and then through a coupling network, which performs impedance matching and optionally galvanic isolation, to a coaxial connector. In the case of fibre-optic application, the serial bit stream is passed through a driver circuit which drives an optical transmitter (LED or LASER) which is coupled to a fibre-optic cable through a connector.

b) Reception path

The incoming data stream from the coaxial cable is first coupled through a connector and coupling network to a circuit which recovers clock and data. In the case of fibre-optic transmission, a light sensitive detector converts light levels to electrical levels which then are passed to a clock and data recovery circuit.

Once the clock and data are recovered, the bit stream is passed to a Biphase Mark decoder. In order to recover byte alignment, a decoder searches in the serial stream for the synchronization word which is necessary to achieve the serial-to-parallel conversion.

Annex D provides further clarification of the characteristics of the SSI and implementation guidelines for clock and data recovery.

A.2 SSI configuration

An SSI interconnection physically consists of two nodes: a transmitting node and a receiving node. This unidirectional optical fibre or copper coaxial cable carrying data from the transmitting node to the receiving node is referred to as a link. The link is used by the interconnected ports to perform communication. Physical equipment such as video or audio compressors, multiplexers, modulators, etc., can be interconnected through these links. This SSI specification clause applies only to the point-to-point type link.

A.3 SSI protocol architecture description

The SSI protocol is divided into three architectural layers for purposes of development of the standard: Layer-0, Layer-1, Layer-2.

A.3.1 Layer-0: Physical requirements

The physical layer defines the transmission media, the drivers and receivers. The transmission uses Biphase Mark encoding.

This subclause provides specifications for the SSI physical layer (Layer-0). Interfaces for coaxial and optical fibre applications are specified. The links are unidirectional point-to-point.

A.3.1.1 Coaxial cable Physical Medium Dependent (PMD) requirement

The nominal cable impedance shall be 75 Ω.

Considering that the transmission data rate is derived from the user data rate, longer links can be achieved for lower user data rates. The physical medium specified in this subclause has the following characteristics. It

– provides a means of coupling the SSI Layer-1 to the coaxial cable segment;

– provides the driving of coaxial cable between a transmitter and a receiver;

– specifies the type and grade of cable and connectors to be used in a synchronous serial interface link.

a) Electrical medium connector

The required connector shall have mechanical characteristics conforming to the BNC type.

NOTE Due to its higher mechanical stability a 50 Ω BNC-type connector according to IEC 60169-8 is recommended.

The electrical characteristics of the connector shall permit it to be used over the frequency range of the specified interface.

The following table A.1 and figures A.4 and A.5 give the requirements for the serial signal launched synchronously on the coaxial cable.

Table A.1 – Transmitter output characteristics

Pulse shape	Conforming to masks shown in figures A.4 and A.5.
Peak-to-peak voltage	1 V ± 0,1 V
Rise/fall time (10 - 90 %)	≤4 ns
Transition timing tolerance (referred to the mean value of the 50 % amplitude points of negative transition)	Negative transition: ±0,2 ns Positive transition at unit interval boundaries: ±1 ns Positive transition at mid interval: ±0,7 ns
Return loss (75 Ω)	–15 dB over frequency range 3,5 MHz to 105 MHz
Maximum peak-to-peak jitter at the output port	2 ns

The digital signal presented at the input port shall conform to table A.2 and figures A.4 and A.5 modified by the characteristics of the interconnecting coaxial pair. The attenuation of the coaxial pair shall be assumed to follow an approximate $\sqrt{f}$ law. The cable shall have a maximum insertion loss of 12 dB at a frequency of 70 MHz.

Table A.2 – Receiver input characteristics

Maximum attenuation at a frequency of 70 MHz assuming a $\sqrt{f}$ law	–12 dB
Maximum peak-to-peak jitter at the input port	4 ns
Return loss (75 Ω)	–15 dB over frequency range 3,5 MHz to 105 MHz
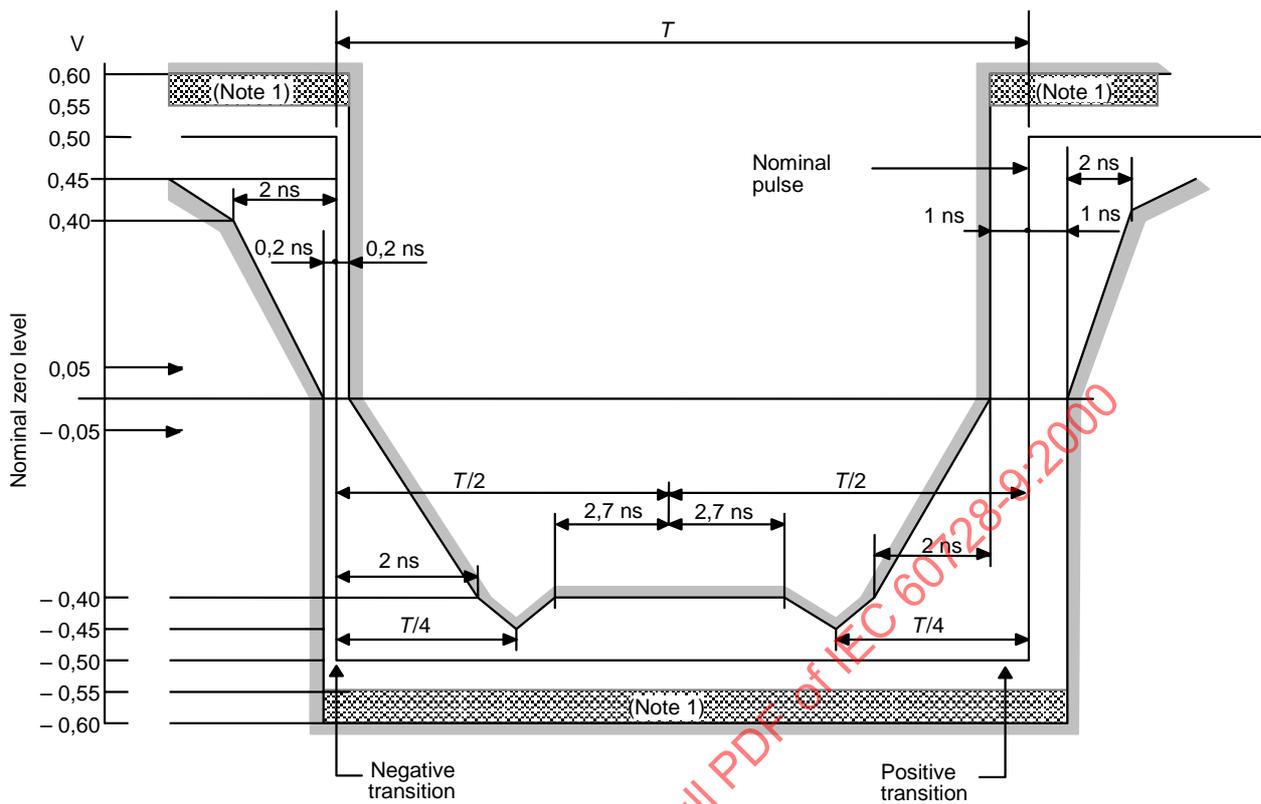

IEC   2195/2000

NOTE 1   The maximum "steady-state" amplitude should not exceed the 0,55 V limit. Overshoots and other transients are permitted to fall into the dotted area, bounded by the amplitude levels 0,55 V and 0,6 V, provided that they do not exceed the steady-state level by more than 0,05 V. The possibility of relaxing the amount by which the overshoot may exceed the steady-state level is under study.

NOTE 2   For all measurements using these masks, the signal should be AC coupled, using a capacitor of not less than 0,02 µF (for data rate = 70 Mbit/s), to the input of the oscilloscope used for measurements.

The nominal zero level for both masks should be aligned with the oscilloscope trace with no input signal. With the signal then applied, the vertical position of the trace can be adjusted with the objective of meeting the limits of the masks. Any such adjustment should be the same for both masks and should not exceed ±0,05 V. This may be checked by removing the input signal again and verifying that the trace lies within ±0,05 V of the nominal zero level of the masks.

NOTE 3   Each pulse in a coded pulse sequence should meet the limits of the relevant mask, irrespective of the state of the preceding or succeeding pulses, with both pulse masks fixed in the same relation to a common timing reference, i.e. with their nominal start and finish edges coincident. The masks allow for HF jitter present in the timing signal associated with the source of interface signal.

When using an oscilloscope technique to determine pulse compliance with the mask, it is important that successive traces of the pulses overlay in order to suppress the effects of low-frequency jitter. This can be accomplished by several techniques; (such as, a) triggering the oscilloscope on the measured waveform, or b) providing both the oscilloscope and the pulse output circuits with the same clock signal). These techniques require further study.

NOTE 4   For the purpose of these masks, the rise time and delay time should be measured between –0,4 V and +0,4 V, and should not exceed 4 ns.

NOTE 5   The inverse pulse will have the same characteristics, noting that the timing tolerances at the level of the negative and positive transitions are ±0,2 ns and ±1 ns respectively.

Figure A.4 – Pulse mask for logical 0

NOTE 1 The maximum "steady-state" amplitude should not exceed the 0,55 V limit. Overshoots and other transients are permitted to fall into the dotted area, bounded by the amplitude levels 0,55 V and 0,6 V, provided that they do not exceed the steady-state level by more than 0,05 V. The possibility of relaxing the amount by which the overshoot may exceed the steady-state level is under study.

NOTE 2 For all measurements using these masks, the signal should be AC coupled, using a capacitor of not less than 0,02 μF (for data rate = 70 Mbit/s), to the input of the oscilloscope used for measurements.

The nominal zero level for both masks should be aligned with the oscilloscope trace with no input signal. With the signal then applied, the vertical position of the trace can be adjusted with the objective of meeting the limits of the masks. Any such adjustment should be the same for both masks and should not exceed ±0,05 V. This may be checked by removing the input signal again and verifying that the trace lies within ±0,05 V of the nominal zero level of the masks.
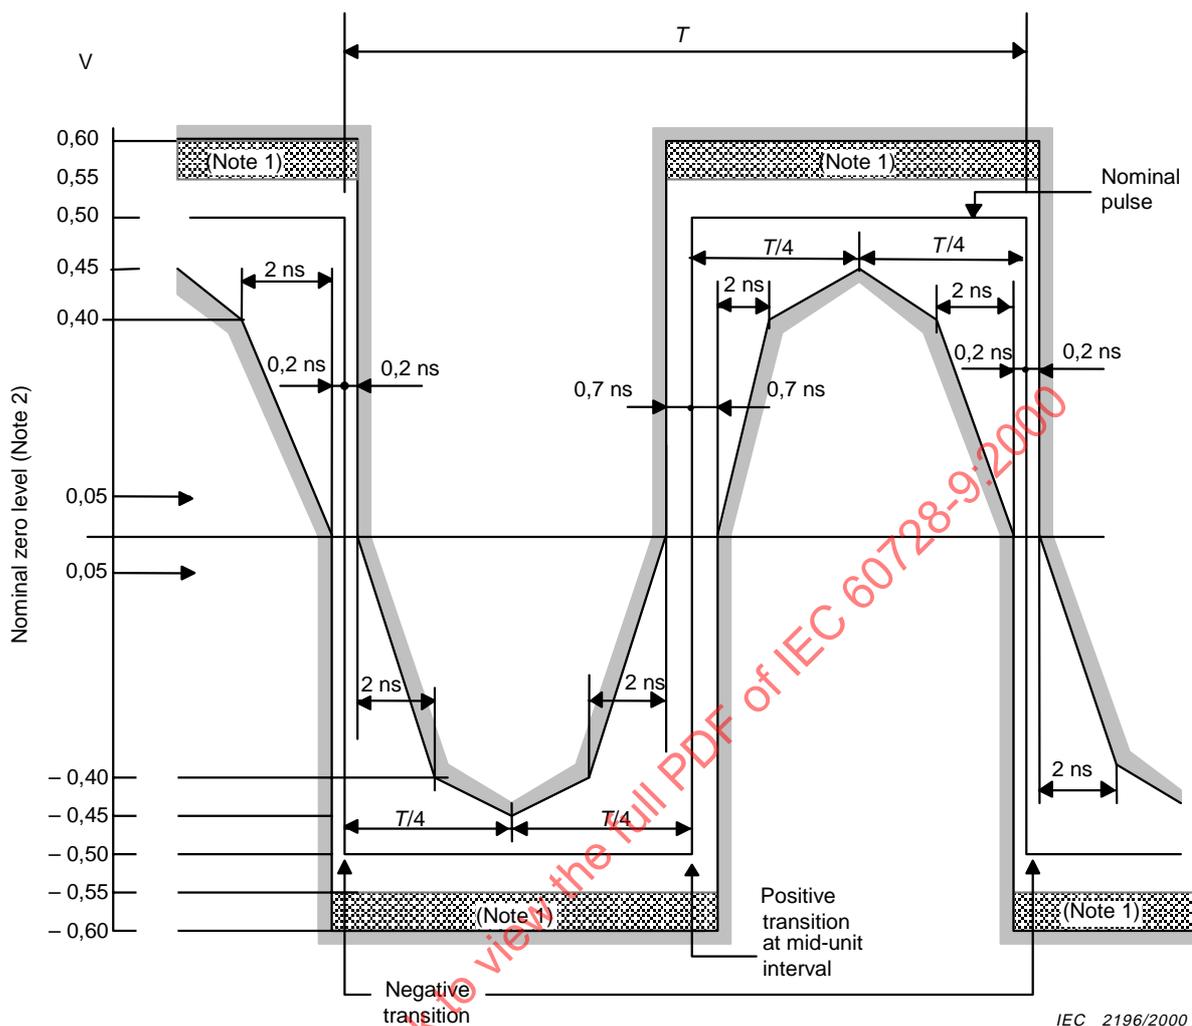

NOTE 3 Each pulse in a coded pulse sequence should meet the limits of the relevant mask, irrespective of the state of the preceding or succeeding pulses, with both pulse masks fixed in the same relation to a common timing reference, i.e. with their nominal start and finish edges coincident. The masks allow for HF jitter caused by intersymbol interference in the output stage, but not for jitter present in the timing signal associated with the source of the interface signal.

When using an oscilloscope technique to determine pulse compliance with the mask, it is important that successive traces of the pulses overlay in order to suppress the effects of low-frequency jitter. This can be accomplished by several techniques (such as, a) triggering the oscilloscope on the measured waveform, or b) providing both the oscilloscope and the pulse output circuits with the same clock signal). These techniques require further study.

NOTE 4 For the purpose of these masks, the rise time and delay time should be measured between −0,04 V and +0,4 V, and should not exceed 4 ns.

Figure A.5 – Pulse mask for logical 1

A.3.1.2   Fibre-optic Physical Medium Dependent (PMD) requirement

Transmission of the SSI data stream on a fibre-optic medium consists of interconnecting transmitter and receiver by a section of optical fibre which can be either multimode or single-mode type. The type of the optical fibre will be determined by the link characteristics, length and type of optical connectors.

The fibres to be used for the serial data interface are specified by ITU-T Recommendations or EN:

Multimode fibre: EN 188 201

Single-mode fibre: ITU-T Recommendation G.654 or EN 188 101

The optical connector shall be of SC type, according to IEC 60874-14.

The optical characteristics of the links are described in table A.3. All parameters shall be met over the temperature, voltage, and lifetime range of the system.

Table A.3 – Optical characteristics for SSI links

Application	Internal connections	Trunk lines		
		Short-haul	Long-haul	
Source nominal wavelength (nm)	1 310	1 310	1 310	1 550
Type of fibre	EN 188201	EN 188101	EN 188101	EN 188101 ITU-T Rec. G.654
Distance (km)	<2	<15	<40	<60

Transmitter				
Source type	LED	LASER Diode	LASER Diode	DFB LASER Diode
Mean launched power (dBm)				
Maximum	–8	–8	–8	0
Minimum	–15	–15	–15	–5

Receiver				
Minimum sensitivity (dBm)	–23	–28	–34	–34
Minimum overload (dBm)	–8	–8	–10	–10
Maximum optical path penalty (dB)	1	1	1	1

A.3.2   Layer-1: Data encoding

The SSI Layer-1 deals with encoding/decoding aspects which are independent of the transmission medium characteristics. Furthermore, this first layer performs the recognition of the three different transmission formats (see figures 6, 7 and 8) in order to allow a fully transparent serialization/deserialization.

Layer-1 operations consist of

– distinguishing the three transmission formats;

– parallel-to-serial conversion of the 8-bit byte with the MSB transmitted first;

– Biphase Mark coding of the serial signal in the transmitter.

The inverse operations are performed in the receiver.

Distinction between the three transmission formats on the serial link is performed as follows:

- the transmission format with 188-byte packets (figure 6) is characterized by a synchronization byte 47H, the periodicity of which is 188 bytes;
- the transmission format with 204-byte packets with 16 dummy bytes (figure 7) is characterized by a synchronization byte 47H, the periodicity of which is 204 bytes;
- the transmission format of packets of 204 bytes with valid extra bytes (figure 8) is characterized by an inverted synchronization byte (B8H), the periodicity of which is 204 bytes.

a) Line coding

A Biphase Mark Code shall be used. Figure A.6a describes the rules of Biphase Mark coding, whereas figure A.6b illustrates that the required medium bandwidth is twice the bandwidth required by NRZ coding.

The encoding rules are as follows:

- a transition always occurs at the beginning of the bit whatever its value is (0 or 1);
- for logical 1, a transition occurs in the middle of the bit;
- for logical 0, there is no transition on the middle of the bit.
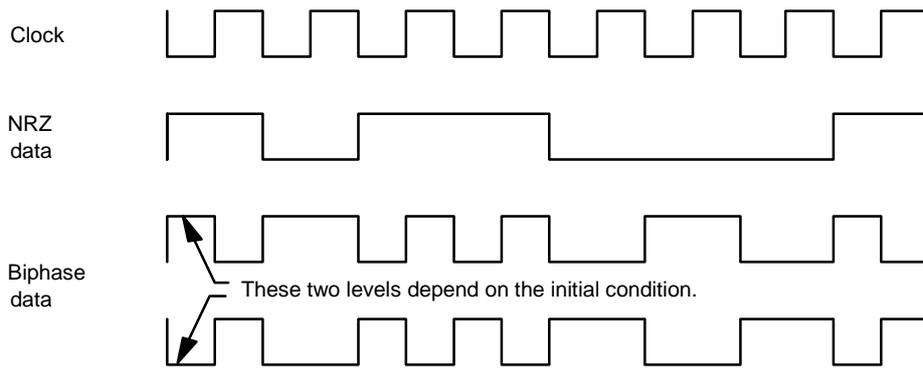

Figure A.6a – Biphase Mark coding scheme

$$\frac{D = f\,(f \times T)}{\text{dB}}$$
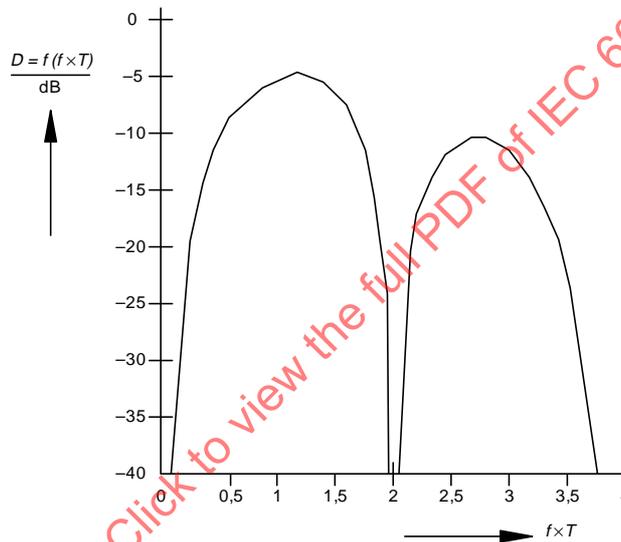

(*T* = the bit duration of NRZ data)

Figure A.6b – Spectral density of Biphase Mark Code

Figure A.6 – Biphase Mark encoding

b) Byte synchronization

The byte synchronization process in the receiving equipment has to take into account the two possible packet formats, i.e. the 188-byte packet format and the 204-byte packet format. The packet synchronization byte (47H or B8H) is used as a byte alignment pattern which serves for initializing the serial-to-parallel conversion. The occurrence of the synchronization byte (188 bytes of 204 bytes) and the value of the synchronization byte (47H or B8H) are used to restore the DVALID signal and the PSYNC signal.

If the received transmission format is a 204-byte packet with valid extra bytes, as indicated in figure 8, the synchronization byte (B8H) must be inverted in order to recover the original synchronization byte (47H) of the TS packet format to be delivered to layer-2.

NOTE   In order to prevent possible synchronization errors, it is recommended that consecutive bytes 47H do not occur within the 188-byte or 204-byte data packet.

c) Clock recovery

   In the receiver the clock recovery circuit extracts the transport clock directly from the encoded data stream. The clock corresponds directly to the user data rate.

d) Bit-Error-Rate (BER) requirement

   The BER shall be less than one part in 10^{13}, as measured where data passes from Layer-1 to Layer-2. That is, BER shall be measured where data emerge from the Biphase Mark decoder.

A.3.3　Layer-2: Transport protocol

The SSI Layer-2 uses the MPEG-2 Transport Stream as defined in ISO/IEC 13818-1 as its basic message unit. The MPEG-2 Transport Packet synchronization byte (47H) is included in this Layer-2 packet definition to allow receive equipment to achieve synchronization.

The Transport Packets shall be presented to Layer-2 either as contiguous 188-byte packets, or separated by 16 dummy bytes, or contiguous Reed Solomon-encoded 204-byte packets.

Annex B
(normative)

Asynchronous Serial Interface (ASI)

This annex describes a system for a serial, encoded transmission of different data rates with a constant transmission rate, based on a layered structure of MPEG Transport Packets according to ISO/IEC 13818-1 as a top layer (Layer-2), and a pair of bottom layers (Layer-1 and Layer-0) based upon the Fibre Channel (FC) described in ISO/IEC 14165-111. Layer-1 and Layer-0 are based upon a subset of Fibre Channel Levels FC-1 and FC-0.

Transport Streams from different sources may have different data rates. The use of a constant transmission rate permits a constant receiver clock. To restore the original clock rate, a PLL circuit can be used. Annex E gives some proposals for how such a circuit can be designed. The input of the required transmission facility accepts MPEG-2 bytes and the output delivers MPEG-2 bytes.

While the Fibre Channel (FC) supports single-mode fibre, multimode fibre, coaxial cable and twisted pair media interfaces, this standard defines only two distinct forms of interfaces: coaxial cable and multimode fibre-optical cable using LED emitters.

Instead of a transmission rate of 265,625 Mbit/s, as required in ISO/IEC 14165-111, in this standard the transmission rate is 270,000 Mbit/s.

B.1   ASI transmission system overview

Figures B.1 and B.2 represent the primary components of the ASI transmission method over copper coaxial cable and fibre-optic cable, respectively.
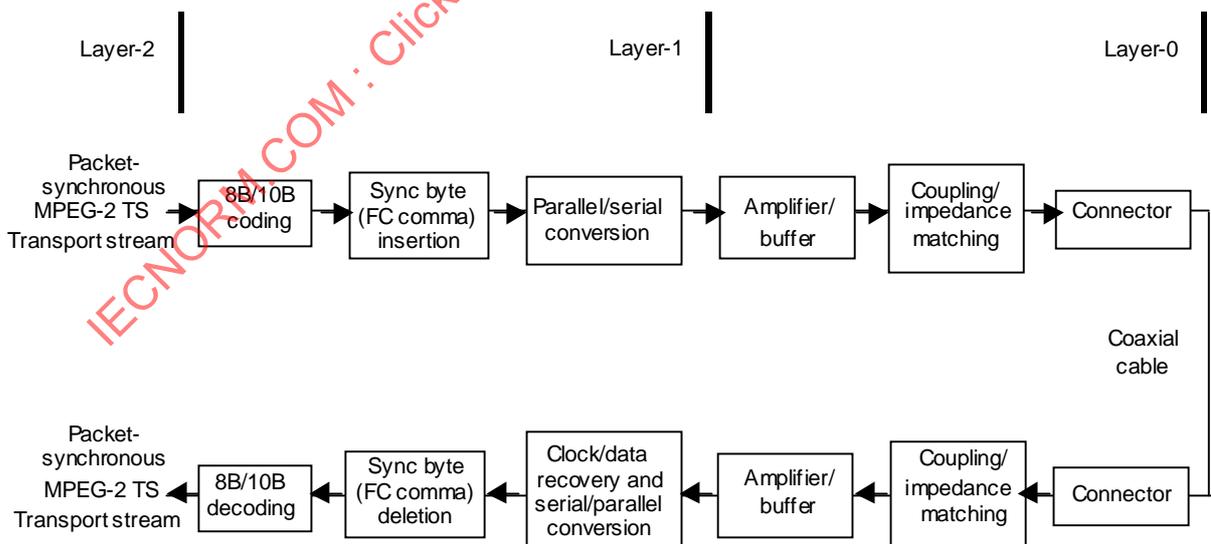

IEC   2199/2000

Figure B.1 – Coaxial cable-based asynchronous serial transmission link (ASI type)
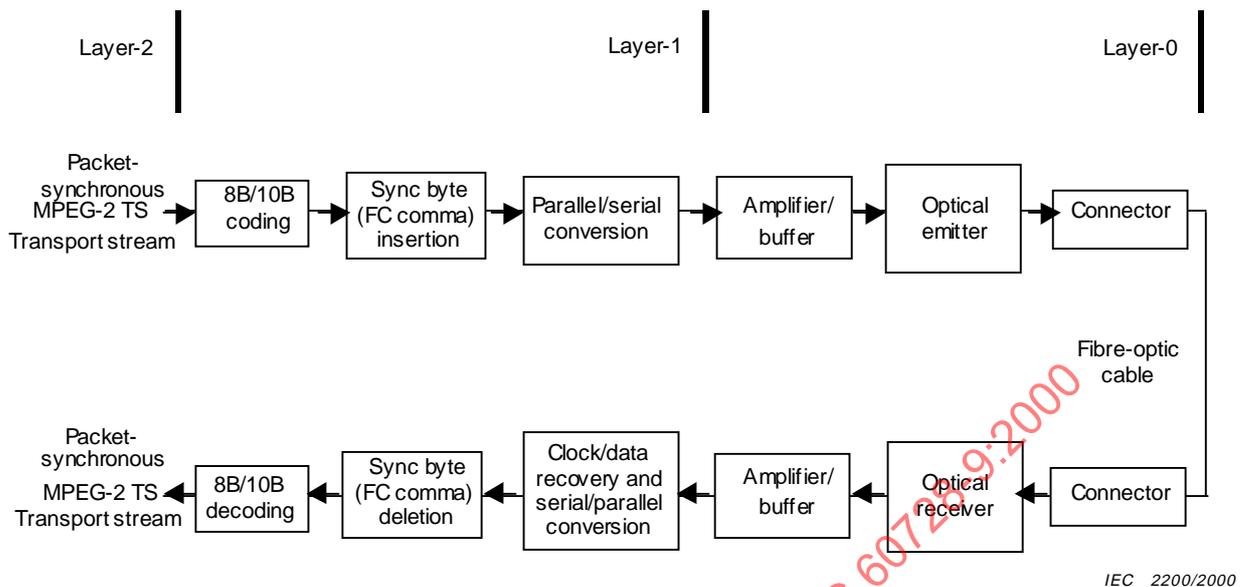

Figure B.2 – Fibre-optic-based asynchronous serial transmission link (ASI type)

Data to be transmitted are presented in byte-synchronized form as MPEG-2 Transport Packets. Bytes are then 8B/10B coded, which produces one 10-bit word for each 8-bit byte presented. These 10-bit words are then passed through a parallel-to-serial converter which operates at a fixed output bit-rate of 270 Mbit/s. If the parallel-to-serial converter requests a new input word and the data source does not have one ready, a synchronization word shall be inserted. These sync words are to be ignored by receive equipment. In the case of coaxial cable application, the resulting serial bit-stream is typically passed to a buffer/driver circuit and then through a coupling network to a coaxial connector. In the case of fibre-optic application, the serial bit-stream is passed to a driver circuit which drives an LED emitter which is coupled to a fibre-optic cable through a mechanical connector.

Receive data arriving on a coaxial cable are first coupled through a connector and coupling network to a circuit which recovers clock and data. In the case of fibre-optic transmission, a light-sensitive detector converts light levels to electrical levels which are then passed to a clock and data recovery circuit.

Recovered serial data bits are passed to a decoder which converts the 10-bit transmission words back into the 8-bit bytes originally transmitted. In order to recover byte alignment, the decoder initially searches for synchronization words; the synchronization word is a unique 10-bit pattern which is prevented from occurring (by the 8B/10B encoder) with all possible input data bytes. Once found, the start of the synchronization word marks the boundary of subsequent received data words and establishes proper byte-alignment of decoder output bytes.

B.2   ASI configuration

An ASI interconnect physically consists of two nodes: a transmitting node and a receiving node. This unidirectional optical fibre or copper coaxial cable carrying data from the trans-mitting node to the receiving node is referred to as a link. The link is used by the interconnected ports to perform communication. Physical equipment such as video or audio compressors, multiplexers, modulators, etc., can be interconnected through these links. This ASI specification applies only to the point-to-point type link.

B.3   ASI protocol architecture description

The ASI protocol is divided into three architectural layers for purposes of development of the standard: Layer-0, Layer-1 and Layer-2.

B.3.1   Layer-0: Physical requirements

The physical layer defines the transmission media, the drivers and receivers, and the transmission speeds. The physical interface provides for both LED-driven multimode fibre and copper coaxial cable. The base speed is defined as 270 Mbit/s (transmission channel speed). The basic unit of Layer-0 is the link. The points where conformance is required are shown as point S and R in the figure B.3.
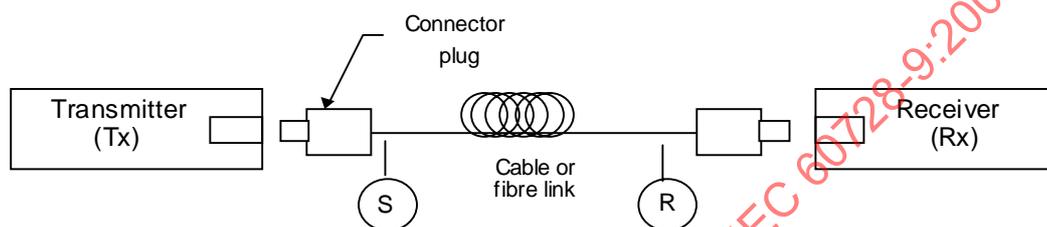

IEC   2201/2000

Figure B.3 – Serial link Layer-0 reference points

In coaxial applications, jitter is specified in the traditional manner of random and data dependent jitter and duty-cycle distortion. In LED-driven fibre-based applications, jitter is specified in terms of Random Jitter (RJ) and Deterministic Jitter (DJ). Deterministic Jitter is the sum of data-dependent jitter and duty-cycle distortion. The DJ is due to the timing distortions caused by normal circuit effects in the transmission system. It is comprised of the propagation delay difference between the rising and falling edge of a signal and the interaction of limited bandwidth of the transmission components and the symbol sequence. The RJ is due to the thermal noise in the system and usually modelled as a Gaussian process.

a) Line rates and bit timing

The encoded line rate with the 8B/10B block code is 270 Mbit/s which results in a media transmission rate of 270 MBd. At the transmitter the serialization is done using a fixed oscillator to establish this 270 MBd rate from which a phase-locked byte clock is derived and used to shift in parallel bytes.

Receivers recover the serial transmission clock generally by the use of a phase-locked-loop (PLL) oscillator locked to bit transitions of the incoming data stream. A phase-locked byte clock is derived from this recovered serial bit clock and is used to shift parallel bytes out to Layer-1 processing elements.

It is required that the encoded line rate shall be 270 MBd $\pm$ (100×10^{-6}).

b) Receiver timing acquisition

A receiver shall first acquire bit synchronization, before attempting to align received bytes. This time is measured from receipt of a valid input to the time the receiver is synchronized to the bit stream and delivering valid re-timed data within the BER objective of the system.

It is required that bit synchronization shall occur in not more than 1 ms.

B.3.1.1 Electrical medium characteristics

The nominal cable impedance shall be 75 Ω.

a) Electrical medium connector

The required connector shall have mechanical characteristics conforming to the BNC type.

NOTE Due to its higher mechanical stability a 50 Ω BNC-type connector according to IEC 60169-8 is recommended.

The electrical characteristics of the connector shall permit it to be used over the frequency range of the specified interface.

b) Electrical characteristics

The parameters shall be met over the temperature, voltage and lifetime range of the system. Electrical measurements shall be made with the interface terminated with the connector specified above into 75 Ω resistive termination. Full electrical details are provided in table B.1.

Table B.1 – Electrical characteristic specifications for ASI link

Transmitter output characteristics	Units	
Output voltage (p-p)	mV	800 ± 10 %
Deterministic Jitter (DJ) (p-p)	%	10
Random Jitter (RJ) (p-p)	%	8
Return loss	dB	Under consideration
Maximum rise/fall time (20 - 80 %)	ns	1,2

Receiver input characteristics	Units	
Minimum sensitivity (D21.5 idle pattern)	mV	200
Maximum input voltage (p-p)	mV	880
s_{11} (range: 0,1 to 1,0 × bit rate)	dB	−17
Minimum discrete connector return loss (5 MHz - 270 MHz)	dB	−15

The interface shall be coupled to the coaxial system via a transformer.

As measured according to the diagram in figure B.4, the eye opening provided by the transmitter shall be within the mask depicted in figure B.5.
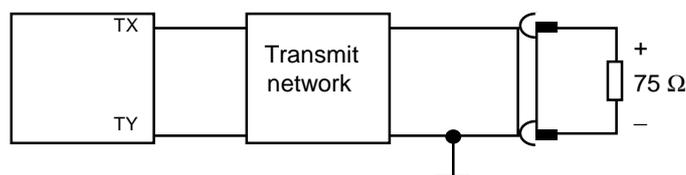

IEC 2202/2000

Figure B.4 – Coaxial transmitter test circuit
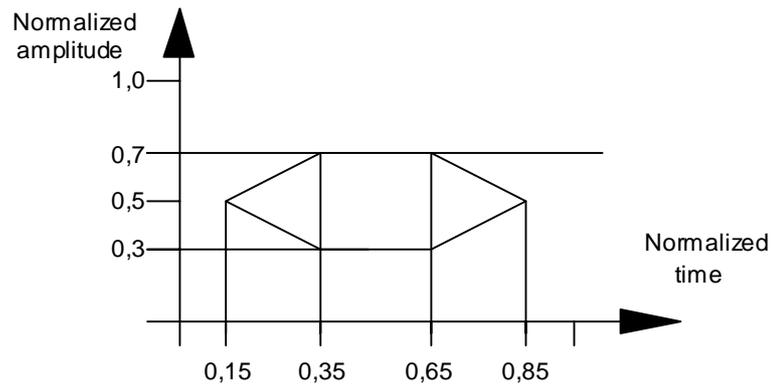

Figure B.5 – Transmitter eye diagram for jitter

B.3.1.2   Fibre-optic medium characteristics

The fibre-optic medium consists of a single section of fibre-optic cable connecting a transmitter and receiver. The optical medium requirements are satisfied by a fibre with a nominal diameter of 62,5/125 μm specified by IEC 60793-2, type A1b, with the exceptions noted below. The system can operate, subject to certain restrictions, with a variety of optical fibres; however, performance to this specification and interoperability between vendors, equipment is assured only through the use of the optical fibre specified in this subclause. This specification was developed on the basis of an attenuation value of less than or equal to 1,5 dB/km, when measured at a wavelength of 1 300 nm. Higher loss fibre may be used for shorter fibre cable lengths.

Each optical fibre shall have a zero dispersion wavelength in the range of 1 295 nm to 1 365 nm and a dispersion slope not exceeding 0,110 ps/(km × m2). Each optical fibre shall have a dispersion characteristic in the range shown in table B.2 below:

Table B.2 – Chromatic dispersion requirements

Zero dispersion wavelength λ_0 (nm)	Maximum dispersion slope S_0 [ps/(km × nm2)]
1 295 - 1 300	[λ_0 - 1 190]/1 000
1 300 - 1 348	0,110
1 348 - 1 365	1 458 - λ_0]/1 000

a) Optical medium connector

   Fibre-optic cable connectors shall be of SC type according to IEC 60874-14.

b) Optical characteristics

   The transmit interface and receive interface parameters for 270 Mbit/s multimode fibre interface shall be as summarized below. The parameters shall be met over the temperature, voltage, and lifetime range of the system. Optical measurements shall be made with the cable terminated with the optical connector and the optical fibre specified above. Fibre length shall be sufficient to ensure equilibrium mode distribution. Methods of measurements are given in IEC 60728-6.

The complete specification is given in the following table B.3 and associated figure B.6.

Table B.3 – Optical characteristic specifications for ASI link

Fibre link parameters	Units	
Fibre core diameter	µm	62,5

Transmitter parameters	Units	
Type		LED
Spectral centre wavelength	nm	1 280 (min.)
	nm	1 380 (max.)
Maximum spectral width	nm FWHM	See figure B.6
Average launched power	dBm	−20 (min.)
	dBm	−14 (max.)
Minimum extinction ratio	dB	9
Deterministic Jitter (DJ) (p-p)	%	16
Random Jitter (RJ) (p-p)	%	9
Maximum optical rise/fall time	ns	2,0/2,2

Receiver parameters	Units	
Average received power	dBm	−26 (min.)
	dBm	−14 (max.)
Deterministic Jitter (DJ) (p-p)	%	19
Random Jitter (RJ) (p-p)	%	9
Maximum optical rise/fall time	ns	3,0
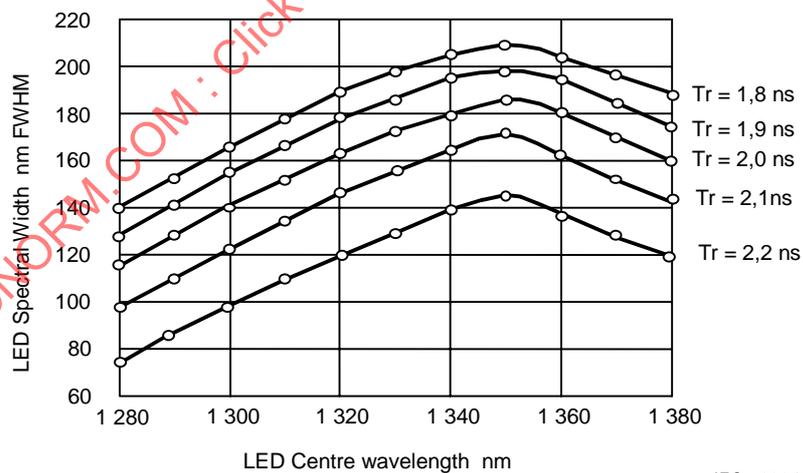

IEC   2204/2000

Figure B.6 – Spectral width of transmitter

B.3.2   Layer-1: Data encoding

The ASI transmission protocol includes serial encoding rules, special characters, and error control. It uses a DC balanced 8B/10B transmission code. The code maps each 8-bit data byte into a 10-bit code with the following properties: a run length of 4 bits or less and minimal DC offset. This code provides error checking through both invalid transmission code points and the notion of 'running' disparity.

Special characters are defined as extra code points beyond the need to encode a byte of data. One in particular, the comma character (K28.5 in the tables of annex C) is used to establish byte synchronization in the ASI transmission link.

a) Coding requirements

The ASI transmission Layer-1 deals with encoding/decoding aspects which are independent of the transmission medium characteristics. At Layer-1, 8B/10B transmission coding is employed which provides for both a self-checking capability and byte synchronization of the link. The 10B transmission code is defined in terms of "disparity", i.e. the difference in the number of "1" bits and "0" bits in the transmitted serial data stream. It is through the disparity characteristics of the code that DC balance is maintained. Each 8B code point has two entries in the 10B code point map corresponding to the positive and negative disparity representation for that 8B code point. The transmitter is required to maintain the running disparity of the transmitted serial bit stream within ±1 of a neutral point by selection of the appropriate positive or negative disparity representation of the 10B code to be transmitted. The receiver will check the incoming bit stream for proper running disparity and invalid 10B code points to ensure byte level data integrity.

b) Line coding

The 8B/10B transmission code specified in ISO/IEC 14165-111 shall be the encoding method utilized in ASI interface Layer-1. Annex C is a reproduction of the 8B/10B coding table from that standard and a brief description of the coding process.

NOTE   The ASI coding is not invariant to logical inversion of the transmitted bits. Therefore, to ensure correct operation, care must be taken that equipment interface circuitry of the non-inverting type is used.

c) Byte synchronization

The byte alignment synchronization pattern shall be the K28.5 code of the 8B/10B code. The receiver shall present a properly aligned byte stream after the receipt of two K28.5 special characters aligned on the same byte boundary within a 5-byte window. The first byte received after the second K28.5 shall have valid byte alignment.

d) Bit-Error-Rate (BER) performance

The BER shall be less than one part in 10^{13}, as measured where data passes from Layer-1 to Layer-2. That is, BER shall be measured where bytes emerge from the 8B/10B decoder.

e) Packet synchronization

At least two synchronization code words (K28.5) shall immediately precede every Layer-2 Transport Packet.

B.3.3   Layer-2: transport protocol

The ASI Transmission Layer-2 standard uses the MPEG-2 Transport Stream Packet as defined in ISO/IEC 13818-1 (Systems) as its basic message unit. Optionally, the RS-coded byte structure as specified in ETS 300 429 is also supported. Transport packets can be transmitted as a block of contiguous bytes (that is, with no intervening sync bytes in the transmitted stream for a single packet) or as individual bytes with intervening sync bytes, or any combination of contiguous bytes and sync bytes. Additionally, the ASI Layer-2 protocol specifies that at least two synchronization words (K28.5) precede each transport packet.

NOTE   The MPEG-2 Transport Packet Synchronization word (47H) is included in this Layer-2 packet definition to allow receiving equipment to achieve packet synchronization. The packet synchronization process is not a part of this ASI Transmission protocol definition.

a) Transport requirements

The ASI interface Layer-2 definition employs the MPEG-2 Transport Stream packet syntax with the additional requirement that every Transport Packet shall be preceded with at least two K28.5 synchronization characters. Although 8B/10B receivers can generally maintain synchronization (once initially synchronized) without interspersed synchronization codes, this leading sync byte requirement will allow re-sync within one Transport Packet in the event that a line disturbance causes loss of sync.

b) Transport packet format

Transport packet structure shall conform to the specifications of ISO/IEC 13818-1 and ETS 300 429 for Transport Stream Packets. The packet length can be 188 bytes or 204 bytes.

c) Transport packet timing

Transport packets may be presented to Layer-2 either as a burst of contiguous bytes as shown in figure B.7, or as individual bytes spread out in time as shown in figure B.8. (These figures reflect the result of these types of packet delivery as seen at Layer-1.)

Table C.2 – Valid special characters

Special Code N	Current RD – abcdei fghj	Current RD + abcdei fghj
K28.0	001111 0100	110000 1011
K28.1	001111 1001	110000 0110
K28.2	001111 0101	110000 1010
K28.3	001111 0011	110000 1100
K28.4	001111 0010	110000 1101
K28.5	001111 1010	110000 0101
K28.6	001111 1000	110000 1001
K23.7	111010 1000	000101 0111
K27.7	110110 1000	001001 0111
K29.7	101110 1000	010001 0111
K30.7	011110 1000	100001 0111

The terminology of encoding used in table C.1 is described as follows:

Data byte	d7	d6	d5		d4	d3	d2	d1	d0		
8B information character	H	G	F		E	D	C	B	A		
10B transmission character	a	b	c	d	e	i		f	g	h	j

Bit a is transmitted first. Each transmission character in the table (valid data character) is associated with a name Dx.y, where

x   is the decimal value of the bits EDCBA

$(x)_{dec} \equiv (EDCBA)_{bin}$

y   is the decimal value of the bits HGF

$(y)_{dec} \equiv (HGF)_{bin}$

In addition there are further 10B code words named Valid Special Characters Kx.y (see table C.2). Only the Special Character: K28.5 (Comma) is here used as stuffing data and for byte synchronization.

Example

Encoding of the MPEG synchronous byte 47_{hex} = 0100 0111 (Data byte name D7.2).

8B information character	0	1	0		0	0	1	1	1		
10B transmission character RD+	1	1	1	0	0	0		0	1	0	1
10B transmission character RD−	0	0	0	1	1	1		0	1	0	1

Encoding depends on the parameter RD (Running Disparity). RD determines the ratio of zeros and ones during the transmission. Switching between the code words depending on the RD in the transmitter and receiver maintains the DC balance. RD is calculated based on two sub-blocks: bits abcdei and bits fghj of the transmission character. RD at the beginning of a sub-block is the calculated RD of the last sub-block. RD at the end of any sub-block is positive, if the sub-block contains more ones than zeros, or if the sub-block is 000111 or 0011. RD at the end of any sub-block is negative, if the sub-block contains more zeros than ones, or if the sub-block is 111000 or 1100. Otherwise, the last RD is taken. Initialization of the transmitter is done with negative RD; the transmitter may either assume the positive or the negative RD. Independent of the validity of the transmission characters the received transmission characters shall be used as the receiver's current RD for the next transmission character.

The redundancy of the 8B/10B transmission code can be used for error detection.

Code violations may result from a prior error which altered the RD of the bit stream, causing a detectable error at the current transmission character. The example in table C.3 shows this behaviour.

Table C.3 – Delayed code violation example

		RD	Character 1	RD	Character 2	RD	Character 3	RD
Transmitted character stream	−	D21.1	−	D10.2	−	D23.5	+
Transmitted bit stream	−	101010 1001	−	010101 0101	−	111010 1010	+
Bit stream after error	−	101010 1011	+	010101 0101	+	111010 1010	+
Decoded character stream	−	D21.0	+	D10.2	+	Code violation	+

Annex D
(informative)

Implementation guidelines and clock recovery from the
Synchronous Serial Interface (SSI)

D.1   Example of implementation of the SSI interface

Hardware implementation of the proposed SSI interface was undertaken in order to validate the serial transmission in a real MPEG-2 chain including TS multiplexer, QPSK modulator/demodulator, QAM modulator/demodulator.

It consists of two adapter modules:

– an emitting module which transforms the parallel interface, such as described in 4.1, into the serial mode;

– a receiving module which performs the reverse function in recovering the Transport Packets conforming to the parallel interface.
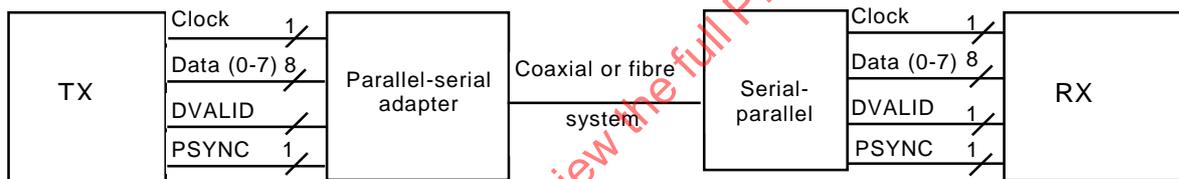

IEC 2207/2000

Figure D.1 – Connection of the adapter modules

D.2   Emitting module

The main functions are:

– parallel-to-serial conversion;

– generation of the serial clock by a multiplication by 8 of the parallel clock;

– Biphase-Mark encoding.

As an example, using a Manchester Biphase Mark encoder:

– LED driver for optical transmission;
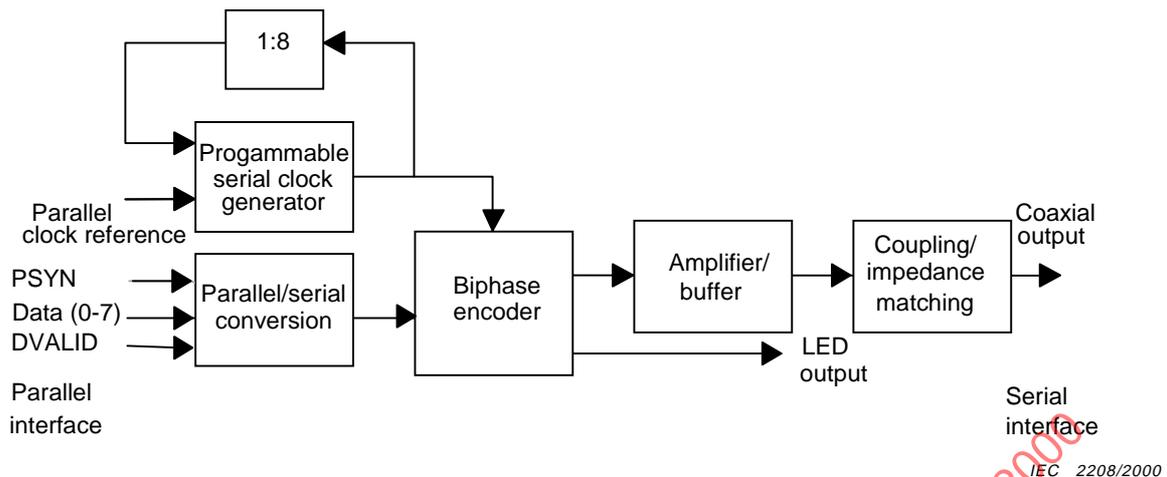

– cable driver for coaxial transmission.

Figure D.2 – Example of implementation of an emitting module

IEC   2208/2000

D.3   Receiving module

The byte synchronization process in the receiving equipment has to take into account the two possible packet formats, i.e. the 188-byte packet format and the 204-byte packet format.

An automatic byte synchronization is performed as follows:

–   a first attempt of synchronization can be done on the hypothesis of 188-byte packet format;

–   if the first attempt is unsuccessful, the synchronization is done on the 204-byte packet format.

The main functions are:

–   cable equalizer for coaxial reception;

–   optical receiver for optical reception;

–   clock recovering and Biphase Mark decoding.

As an example, using a Manchester Biphase Mark decoder:

–   byte synchronization and deserialization.

IEC   2209/2000
