## Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing documents is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular, the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see [www.iso.org/directives](http://www.iso.org/directives)).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see [www.iso.org/patents](http://www.iso.org/patents)).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation of the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT), see [www.iso.org/iso/foreword.html](http://www.iso.org/iso/foreword.html).

This document was prepared by Technical Committee ISO/TC 27 *Solid mineral fuels*, Subcommittee SC 1, *Coal preparation. Terminology and performance*.

This second edition cancels and replaces the first edition (ISO 10752:1994), of which it constitutes a minor revision.

The main changes compared to the previous edition are as follows:

- editorial corrections throughout the document.

Any feedback or questions on this document should be directed to the user's national standards body. A complete listing of these bodies can be found at [www.iso.org/members.html](http://www.iso.org/members.html).

## Introduction

A standard expression of performance is required to define the accuracy of separation of a particular item, to assist in the comparison of the performance of different items of coal sizing equipment and in the prediction of separation results.

# Coal sizing equipment — Performance evaluation

## 1 Scope

This document describes the principles and methods for the expression of results of performance tests on sizing equipment used in coal preparation, and includes methods for the evaluation of performance parameters. Performance test procedures and size measurement techniques are recommended.

This document applies to all types of sizing equipment, categorized as follows:

- a) screens;
- b) classifiers;
- c) others.

The procedure described in this document applies to two-product separations. Performance assessment of multiproduct separations can be achieved by consideration of a series of two-product separations.

## 2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

ISO 1213-1, *Solid mineral fuels — Vocabulary — Part 1: Terms relating to coal preparation*

ISO 13909, *Hard coal and coke — Mechanical sampling*

ISO 18283, *Hard coal and coke — Manual sampling*

## 3 Terms and definitions

For the purposes of this document, the terms and definitions given in ISO 1213-1 and the following apply.

ISO and IEC maintain terminological databases for use in standardization at the following addresses:

- ISO Online browsing platform: available at <https://www.iso.org/obp>
- IEC Electropedia: available at <http://www.electropedia.org/>

### 3.1 General

#### 3.1.1

##### **actual feed**

*F*

material fed to the sizing equipment during the test period and including any recirculated material

#### 3.1.2

##### **coarser material**

material that is coarser than the reference size

#### 3.1.3

##### **finer material**

material that is finer than the reference size

**3.1.4**

**product**

material discharged from the sizing equipment prior to any further treatment or recirculation

**3.1.5**

**coarser product**

*c*

product of size separation that contains a greater proportion of coarser material than does the feed

**3.1.6**

**finer product**

*f*

product of size separation that contains a greater proportion of finer material than does the feed

**3.1.7**

**sharpness of separation**

$E_{pm}$

assessment of the deviation from a perfect separation, usually expressed in terms of mean probable error

**3.2 Performance parameters**

**3.2.1**

**theoretical yield (sizing)**

maximum yield of a product at a reference size, as determined from the size distribution curve for the reconstituted feed

**3.2.2**

**coarser material placement efficiency**

$E_c$

percentage of coarser material in the reconstituted feed that reports to the coarser product

**3.2.3**

**finer material placement efficiency**

$E_f$

percentage of finer material in the reconstituted feed that reports to the finer product

**3.2.4**

**overall separation index**

sum of the coarser material placement efficiency and the finer material placement efficiency minus 100

**4 Performance criteria**

The following criteria should be determined where applicable:

- a) feed rate;
- b) reference size of separation;
- c) sharpness of separation;
- d) misplaced material;
- e) material placement efficiencies;
- f) the degree of difficulty of separation;
- g) material characteristics.

NOTE 1 The above criteria will be influenced by test conditions which should therefore be fully reported.

NOTE 2 It is essential that prediction of separation results takes into account the influence of test conditions.

NOTE 3 It is essential that test conditions are made compatible to ensure valid comparisons.

NOTE 4 Conditions should be kept uniform during a test.

## 5 Performance parameters

For the standard expression of performance of a separation, the criteria given in [Clause 4](#) should be determined by the following parameters:

- a) the feed rate, expressed on mass and/or volume bases;
- b) the reference size, preferably expressed as both partition size and equal errors size;

NOTE It is recognized that partition size is not always obtainable from the results of a size separation and that an alternative reference size therefore has to be employed. To allow comprehensive comparison of performance, it is recommended that parameters based on equal errors size as the reference be included, in addition to those based on partition size.

- c) the sharpness of separation, expressed in terms of probable error;
- d) the distribution of misplaced material in each product, presented graphically with respect to size, and the particular values of misplaced material in each product on both feed and product bases, each determined at the reference size of separation;
- e) the material placement efficiencies expressed as:
  - 1) coarser material placement efficiency,  $E_c$ ;
  - 2) finer material placement efficiency,  $E_f$ ;
  - 3) overall separation index derived from 1) and 2);
- f) the degree of difficulty of separation, expressed in terms of near-size material;
- g) other relevant characteristics of the feed material.

## 6 Performance test procedures

The equipment to be tested, the actual feed composition, and the means of handling the feed and products vary widely. A single standard procedure is not applicable. The following general recommendations are made.

- a) The average feed rate and/or product flow rates should be determined by the most accurate method possible in the particular circumstances. Typical procedures that may be used are:
  - 1) direct assessment of the mass and/or volume of the whole of the feed or product during the test;
  - 2) continuous assessment by means of a calibrated belt weigher or flowmeter and integration during the test;
  - 3) weighing timed increments taken at regular intervals during the test.
- b) Samples should be taken from the actual feed and from each of the products. Sampling techniques, initial number of increments and minimum mass of each increment should be chosen so that all samples taken are representative. Sampling techniques, initial number of increments and minimum mass of increment for solids being conveyed by a fluid should comply with existing document, if available; for solids under other conditions, ISO 13909-1 to ISO 13909-4 and ISO 18283 shall apply as appropriate.

NOTE Representative samples should be taken from all relevant streams to and from the equipment to be tested, to facilitate checking of results and assessment of the effects of degradation.

c) It is essential to determine the feed rate and the actual yield of each product on a dry basis in accordance with ISO 1170. This should be achieved in accordance with one of the following procedures.

- 1) The mass of each product should be determined by one or more of the following methods:
  - i) direct weighing of the whole of each product collected over the duration of the test or through continuous weighing and integration over the duration of the test;
  - ii) taking regular timed increments over the duration of the test;
  - iii) weighing each product collected simultaneously over a selected timed period during the test.

NOTE 1 The methods given in 1) are listed in order of reliability.

NOTE 2 If it is feasible to measure both the mass of the feed (by belt weigher, weigh hopper, flowmeter, etc.) and the mass of the products, this provides a check.

NOTE 3 If the mass of one of the products cannot be measured, it can be obtained from a mass balance between the feed and products.

NOTE 4 Where the solids are conveyed by a fluid, it can be more convenient to make volumetric measurements.

Representative samples should be taken from relevant streams to determine moisture contents or concentrations of solids as appropriate, so that the results can be reported on a dry basis.

- 2) In circumstances that prevent the weighing of sufficient streams, size analyses of feed and products can be used to determine the percentage yield of each product, as described in [Annex A](#).

In all circumstances, the method used to determine the actual yield of each product should be reported with each respective value in [Table 3](#).

## 7 Analytical procedures

The method and procedure of size analysis should be selected, as far as possible, to be in agreement with the principle of the equipment under test, to produce results in compatible terms. For example, the results of size analysis by sieving would be compatible with vibrating screens, and the results of size analysis by a series of small cyclones would be compatible with cyclone separators. Size analysis by sieving should be carried out in accordance with ISO 1953. The method and apparatus used, and the basis of the percentages (by mass or volume), shall be stated in the data sheet and in [Table 1](#).

The feed sample and each of the product samples should be subjected to size analyses in which the ratio of the upper and lower size limits does not exceed 2:1 for each size fraction. It is recommended that this ratio for size limits be reduced to  $\sqrt{2}:1$  for a minimum of two fractions, both above and below the reference size.

NOTE 1 In some circumstances, a ratio of size limits closer than  $\sqrt{2}:1$  may be necessary in the region of the reference size, to ensure that each of the size fractions contains not more than 10 % of the sample.

NOTE 2 Size distribution curves for the products can be used for:

- a) providing data for additional partition coefficients;
- b) averaging analytically determined values to improve the derived partition curve.

## 8 Evaluation and presentation of performance characteristics

### 8.1 General

All data shall be evaluated and presented in one data sheet, three tables and three figures as follows:

- a) data sheet — test and equipment data;
- b) [Table 1](#) — size distribution of feed and products;
- c) [Table 2](#) — partition coefficients and misplaced material data;
- d) [Table 3](#) — statement of sizing equipment performance;
- e) [Figure 1](#) — partition curve;
- f) [Figure 2](#) — size distribution curve for the reconstituted feed;
- g) [Figure 3](#) — misplaced material curves.

The presentation of the test data may be accomplished by the procedure described below. The specified tabular and graphical formats are given in [Clause 9](#). Specific worked examples are included in [Annexes B, C and D](#).

NOTE 1 Primary calculation procedures are shown in [tables 1 and 2](#). A column number in parentheses denotes a respective value taken from that column.

NOTE 2 The origins of plotted values are shown in [Figures 1 and 2](#) by reference to table and column numbers.

NOTE 3 Reference to definitions of performance parameters in [Clause 3](#) supports the brief explanation of their derivation given in relevant subclauses and in [Tables 1 and 2](#).

### 8.2 Basic data

The data obtained from a performance test comprise the size analyses of the actual feed and the coarser and finer products and the proportion of material reporting to each product. These basic data are compiled in [table 1](#), columns 1 to 8, and calculated on a reconstituted feed basis in columns 9 to 12.

### 8.3 Reconstituted feed size distribution

The size distribution curve for the reconstituted feed is constructed as shown in [Figure 2](#), by plotting the cumulative percent less than the upper size limit (column 12 of [Table 1](#)) against the upper size limit (column 1 of [Table 1](#)).

NOTE It is convenient to use a logarithmic scale for particle size when plotting size distribution curves, to cover a wide range of sizes and to cater for size limits that are in geometric progression.

### 8.4 Partition curve

The partition curve is constructed as shown in [Figure 1](#), by plotting the value of each partition coefficient against the corresponding mean size. It is recommended that each size fraction be represented by its geometric mean size. Geometric mean sizes and partition coefficients are calculated in [Table 2](#), columns 13 and 14. The recommended scales are:

- size:  $\log_{10}$  1 cycle = 50 mm;
- partition coefficient: 1 % = 2 mm.

NOTE 1 As an alternative to geometric mean size, each size fraction may be represented by its mid-mass particle size, derived from a known functional relationship or estimated from the reconstituted feed curve.

NOTE 2 As an alternative method of construction, partition coefficients can be plotted as a histogram on a reconstituted feed base, producing an area representative of mass. An intermediate curve is then drawn by equalizing areas within each size fraction. Performance parameters are derived by applying values obtained from the intermediate curve to the size distribution curve for the reconstituted feed.

### 8.5 Partition size

The partition size,  $S_{50}$ , is obtained directly from the partition curve and is entered as a performance parameter in the statement of sizing equipment performance in [Table 3](#).

NOTE The partition size can be determined from the misplaced material curves (see [Figure 3](#)) at the minimum value of total misplaced material.

### 8.6 Sharpness of separation

The 25 %,  $S_{25}$ , and 75 %,  $S_{75}$ , intercepts are each read from the partition curve (see [Figure 1](#)) and are entered as primary parameters in the statement of sizing equipment performance in [table 3](#). For symmetrical partition curves, the sharpness of separation may be expressed in terms of the mean probable error ( $E_{pm}$ ) as follows:

$$E_{pm} = \frac{S_{75} - S_{25}}{2} \tag{1}$$

In the more common case of skewed partition curves, the sharpness of separation may be expressed in terms of the upper and lower probable errors as follows.

- Upper probable error =  $S_{75} - S_{50}$
- Lower probable error =  $S_{50} - S_{25}$

The upper probable error and lower probable error parameters may be used separately if one of the intercepts is undefined.

### 8.7 Misplaced material curves

The misplaced materials in the coarser and finer products are calculated, as a percentage of the reconstituted feed, in [Table 2](#), columns 15 and 16. Corresponding values are summed to give total misplaced material tabulated in column 17 of [Table 2](#). The misplaced material curves are constructed, as shown in [Figure 3](#), by plotting values for coarser products (column 15 of [Table 2](#)), finer products (column 16 of [Table 2](#)) and total misplaced materials (column 17 of [Table 2](#)), each against the corresponding upper size limit  $S_1$  (column 1 of [Table 1](#)). The recommended scales are:

- size:  $\log_{10}$  1 cycle = 50 mm;
- misplaced material: 1 % = 5 mm.

If it is necessary to use an alternative scale, this should be a simple multiple of the recommended scale; for an example see [Figure C.3](#).

### 8.8 Misplaced material

The misplaced material is read from each respective curve at the reference size, or sizes (see NOTE 1), and the values are inserted into the statement of sizing equipment performance in [Table 3](#). The value of misplaced material for each respective product is converted to a percentage of that product (see NOTE 2), and the converted values are inserted into the statement in [Table 3](#).

NOTE 1 It is convenient to construct an ordinate on the curves, at the reference size, or sizes, being considered (e.g.  $S_d, S_{50}, S_e$ ), to assist in reading the three intercepting misplaced values.

NOTE 2 All values of misplaced material obtained from the curves are in terms of percentages of the reconstituted feed. Conversion to percentage of the respective product can be obtained by multiplying the corresponding curve by 100 and dividing by the yield value of the product under consideration (i.e.  $Y_c$  or  $Y_f$ ).

NOTE 3 The procedure can be repeated for any other reference size.

## 8.9 Equal errors size

The equal errors size,  $S_e$ , is determined by reading the size that corresponds to the point of intersection of the misplaced material curves for coarser and finer products. Alternatively, the equal errors size can be determined from the size distribution curve for the reconstituted feed, as the size corresponding to the yield of the finer product. The equal errors size is inserted into the statement of sizing equipment performance in [Table 3](#).

## 8.10 Theoretical yield

The theoretical yield value at the reference size, or sizes, is determined, for each of the products, from the size distribution curve for the reconstituted feed. Alternatively, each respective theoretical yield value can be determined by subtracting the misplaced material in the product under consideration from the actual yield ( $Y_c$  or  $Y_f$ ) and adding the misplaced material in the complementary product.

EXAMPLE

$$Y_{c,t} = Y_c - M_c + M_f \quad (2)$$

where

$Y_{c,t}$  is the theoretical yield of the coarser product;

$Y_c$  is the yield value of the coarser product;

$M_c$  is the misplaced material in the coarser product;

$M_f$  is the misplaced material in the finer product.

Theoretical yield values are inserted into the statement of sizing equipment performance in [Table 3](#).

NOTE 1 Misplaced material values are in terms of percentages of reconstituted feed.

NOTE 2 The theoretical yield of the complementary product can be obtained by difference from 100 %.

## 8.11 Material placement efficiency

Material placement efficiencies are evaluated and inserted into the statement of sizing equipment performance in [Table 3](#). The calculations are as follows.

a) Coarser material placement efficiency,  $E_c$ :

$$E_c = \frac{Y_c - M_c}{Y_{c,t}} \times 100 \quad (3)$$

where  $Y_c$ ,  $M_c$  and  $Y_{c,t}$  are as defined in [8.10](#).

b) Finer material placement efficiency,  $E_f$ :

$$E_f = \frac{Y_f - M_f}{Y_{f,t}} \times 100 \quad (4)$$

where

$Y_f$  is the yield value of the finer product;

$Y_{f,t}$  is the theoretical yield of the finer product;

$M_f$  is defined in [8.10](#).

c) Overall separation index ( $S_i$ )

$$S_i = E_f + E_c - 100 \quad (5)$$

NOTE 1 Misplaced material values are in terms of percentage of reconstituted feed.

NOTE 2 Alternative methods are available for the evaluation of the material placement efficiencies.

### 8.12 Near-size material

The near-size material, i.e. material within  $\pm 25\%$  of the reference size or sizes, is determined from the size distribution curve for the reconstituted feed in [Figure 2](#) and is inserted into the statement of sizing equipment performance in [Table 3](#).

Other relevant characteristics of the feed material that influence the degree of difficulty of separation are inserted into the test and equipment data sheet, which varies according to the type of equipment under consideration. Examples of data sheets are given in [Annexes B, C and D](#).

### 8.13 Test and equipment data

The presentation of the results of performance tests on coal sizing equipment shall include a report of the equipment details, test conditions and characteristics of the feed material, particularly those that influence the degree of difficulty involved in the separation. This information is inserted into the test and equipment data sheet. Since the parameters involved will vary for different categories of equipment, a specimen of the data sheet is not included in the general illustration, but models are presented in the specific worked examples given in [Annexes B, C and D](#).

## 9 Tabular and graphical presentation

Blank tables and specimen figures are given. The use of these is illustrated in [Annexes B, C and D](#). The order of presentation shall be as follows:

- a) data sheet — test and equipment data (see [8.13](#));
- b) [Table 1](#) — size distribution of feed and products;
- c) [Table 2](#) — partition coefficients and misplaced material data;
- d) [Figure 1](#) — partition curve;
- e) [Figure 2](#) — size distribution curve for the reconstituted feed;
- f) [Figure 3](#) — misplaced material curves;
- g) [Table 3](#) — statement of sizing equipment performance.

Table 1 — Size distribution of feed and products

1	2	3	4	5	6	7	8	9	10	11	12

## Annex A (informative)

### Calculation of the yield of each product of a size separation from size analyses of feed and product materials

#### A.1 Introduction

[Clause 6](#) lists the methods recommended, in order of reliability, for the determination of the yields of the coarser product,  $Y_c$ , and the finer product,  $Y_f$ , of a size separation.

[Clause 6](#) also describes the circumstances under which these yield values may be calculated from the size analyses of the actual feed and the product materials. The two methods recommended are each based on the principle of least-squares and are outlined in [A.2](#).

It is recognized that several methods exist for the calculation of the yield values, and each can be used with careful interpretation. The recommendations are, however, based on test work carried out under carefully controlled conditions where comparison was made between yield values calculated by several of the available methods, using directly determined values as the standard for comparison.

More sophisticated methods, involving the use of computer programs, are being developed, some of which are already available. Use of these methods can sometimes be justified by the nature of the work involved. Such methods are under review for possible future inclusion in this document.

#### A.2 Recommended methods for the calculation of yield values from the size analysis

##### A.2.1 Symbols

The following symbols have been used in the calculations for both recommended methods.

- $Y_f$  is the fractional yield of finer product;
- $Y_c$  is the fractional yield of coarser product ( $= 1 - Y_f$ );
- $i_F$  is the percentage of the  $i_{th}$  fraction in the actual feed;
- $i_{F(rec)}$  is the percentage of the  $i_{th}$  fraction in the reconstituted feed;
- $i_f$  is the percentage of the  $i_{th}$  fraction in the finer product;
- $i_c$  is the percentage of the  $i_{th}$  fraction in the coarser product.

##### A.2.2 Calculation of yield values from cumulative size analyses

This method is based on a least-squares principle, the yield values being calculated so that the sum of the squared deviations between the reconstituted feed and the actual feed size fractions, taken in terms of the actual feed size fraction, is at a minimum.

Thus:

$$\Sigma \left[ \frac{i_F - i_{F(\text{rec})}}{i_F} \right]^2 = \text{a minimum value} \quad (\text{A.1})$$

Since

$$i_{F(\text{rec})} = Y_f i_f + i_c (1 - Y_f) \quad (\text{A.2})$$

then, by substitution of (A.2) in (A.1)

$$\Sigma \frac{(i_F - Y_f i_f - i_c + Y_f i_c)^2}{i_F^2} = \text{a minimum value}$$

Therefore

$$2 \Sigma \frac{[i_F - i_c - Y_f (i_f - i_c)] \times (i_f - i_c)}{i_F^2} = 0$$

Therefore

$$\begin{aligned} \Sigma \frac{(i_F - i_c)(i_f - i_c)}{i_F^2} &= Y_f \times \Sigma \frac{(i_f - i_c)2}{i_F^2} \\ Y_f &= \frac{\Sigma \frac{(i_F - i_c) - (i_f - i_c)}{i_F^2}}{\Sigma \left[ \frac{i_f - i_c}{i_F} \right]^2} \end{aligned} \quad (\text{A.3})$$

Using the cumulative form of the size analyses of actual feed, finer and coarser products, [Formula \(A.3\)](#) can be rewritten as follows:

$$Y_f = \frac{\Sigma \left[ \frac{(\Sigma i_F - \Sigma i_c)(\Sigma i_f - \Sigma i_c)}{\Sigma i_F^2} \right]}{\Sigma \left[ \frac{\Sigma i_f - \Sigma i_c}{\Sigma i_F} \right]^2} \quad (\text{A.4})$$

Thus, [Formula \(A.4\)](#) will allow calculation of the yield of the finer product from the cumulative size analyses of the actual feed and the finer and coarser products of the size separation.

### A.2.3 Calculation of yield values from elementary size analyses

This method is based on a statistical “goodness of fit” test and is also a least-squares method.

The condition applied is as follows:

$$\Sigma \left[ \frac{i_F - i_{F(\text{rec})}}{i_F} \right]^2 = \text{a minimum value} \quad (\text{A.5})$$

The following equation can be derived from [Formula \(A.5\)](#) by a method similar to that used in [A.2.2](#).

$$Y_f = \frac{\Sigma \left[ \frac{(i_F - i_c)(i_f - i_c)}{i_F} \right]}{\Sigma \left[ \frac{(i_f - i_c)^2}{i_F} \right]} \quad (\text{A.6})$$

[Formula \(A.6\)](#) will allow calculation of the yield of the finer product from the elementary size analyses of the actual feed and the finer and coarser products of the size separation.

### Worked example — Vibrating screen

#### Data sheet 1 — Test equipment data (vibrating screen)

Reference	Date of test	Name of plant
WE/S/1	17/9/83	Standard coal preparation plant

Equipment details and duty	
Type of sizing unit	Double-deck vibrating screen
Nominal size of unit	2,44 m × 6,1 m
Inclination	20°
Type of motion	Circular
Direction of motion	Contra-flow
Stroke	9 mm
Frequency	16 Hz
Number of decks and configuration	2 Superimposed
Deck 1	Relieving
Nominal area	14,9 m <sup>2</sup>
Effective area	13,4 m <sup>2</sup>
Type of deck	Woven wire
Aperture	38,1 mm × 38,1 mm
Open area	77 %
Deck 2	Sizing
Nominal area	14,9 m <sup>2</sup>
Effective area	13,4 m <sup>2</sup>
Type of deck	Woven wire
Aperture	6,35 mm × 6,35 mm
Open area	57 %
Designated size	5,0 mm
Rated capacity	150 t/h Two-product size separation at designated size
Feed characteristics	
Nature of feed	Raw coal
Size limits	<100 mm
Bulk density	1,4 t/m <sup>3</sup>
Total moisture	7,1 %
Surface (free) moisture	5,5 %
Ash (dry basis)	25,0 %

Test conditions			
Test masses			
	Method of de- termination	Mass tonnes	Content % (mm)
Feed	Calculated	945	100,0
Coarser product	Belt-weigher	640	67,6
Finer product	Direct weighing in wagons	305	32,4
Duration of test	7 h 36 min		
Average feed rate	124,5 t/h		
Test samples			
	Method of sampling	Number of increments	Mass of incre- ments kg
Feed	Manual	40	400
Coarser product	Manual	40	400
Finer product	Mechanical	40	100
Method of size analysis	Dry sieving		
Apparatus	Test sieves		

Table B.1 — Size distribution of feed and products (vibrating screen)
