Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular, the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see www.iso.org/directives).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see www.iso.org/patents).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation of the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT), see www.iso.org/iso/foreword.html.

This document was prepared by Technical Committee ISO/TC 211, *Geographic information/Geomatics*, in collaboration with the European Committee for Standardization (CEN) Technical Committee CEN/TC 287, *Geographic Information*, in accordance with the Agreement on technical cooperation between ISO and CEN (Vienna Agreement).

This first edition of ISO 19157-1, together with ISO 19157-3, cancels and replaces the first edition (ISO 19157:2013), which has been technically revised. It also incorporates the Amendment ISO 19157:2013/Amd 1:2018.

The main changes are as follows:

- terminology has been harmonized;
- the unique identification of normative components has been added;
- the definition of the data quality model extension has been added;
- the data quality measures have been moved into a new project on a standard data quality measures register;
- the conformance requirements have been updated;
- the usage of package prefixes for type name has been omitted;
- the 'usability' data quality element has been removed from the model;
- a new clause on extending the standard quality model and the quality measures has been added;
- the abstract test suite has been revised;
- requirements for XML schema implementation have been added;
- information on backwards compatibility with superseded edition of this document has been included.

ISO 19157-1:2023(E)

A list of all parts in the ISO 19157 series can be found on the ISO website.

Any feedback or questions on this document should be directed to the user's national standards body. A complete listing of these bodies can be found at www.iso.org/members.html.

Introduction

Geographic data are increasingly being shared, interchanged and used for purposes other than their producers' intended ones. Information about the quality of available geographic data is vital to the process of selecting a dataset in that the value of data are directly related to their quality. A user of geographic data can have multiple datasets from which to choose. Therefore, it is necessary to compare the quality of the datasets to determine which best fulfils the requirements of the user.

The purpose of describing the quality of geographic data is to facilitate the comparison and selection of the dataset best suited to application needs or requirements. Complete descriptions of the quality of a dataset will encourage the sharing, interchange and use of appropriate datasets. Information on the quality of geographic data allows a data producer to evaluate how well a dataset meets the criteria set forth in its product specification and assists data users in evaluating a product's ability to satisfy the requirements for their particular application. For the purpose of this evaluation, clearly-defined procedures are used in a consistent manner.

To facilitate comparisons, it is essential that the results of the quality are expressed in a comparable way and that there is a common understanding of the data quality measures that have been used. These data quality measures provide descriptors of the quality of geographic data through comparison with the universe of discourse. The use of incompatible measures makes data quality comparisons impossible to perform. This document standardizes the components and structures of data quality measures and defines commonly used data quality measures.

This document recognizes that a data producer and a data user can potentially view data quality from different perspectives. Conformance quality levels can be set using the data producer's product specification or a data user's data quality requirements. If the data user requires more data quality information than that provided by the data producer, the data user can follow the data producer's data quality evaluation process flow to get the additional information. In this case the data user requirements are treated as a product specification for the purpose of using the data producer process flow.

The objective of this document is to provide a framework for defining the quality of geographic data. This includes principles for evaluating quality, a conceptual model for handling quality information, a structure and content of data quality measures, and guidelines for reporting a quality evaluation. The framework is extensible, with rules for how to add additional data quality measures. It also provides for complex dimensions of data quality.

Geographic information — Data quality —

Part 1: General requirements

1 Scope

This document establishes the principles for describing the quality of geographic data. It:

- defines a well-considered system of components for describing data quality;
- defines the process for defining additional, domain-specific components for describing data quality;
- specifies components and the content structure of data quality measures;
- describes general procedures for evaluating the quality of geographic data;
- establishes principles for reporting data quality.

This document is applicable to data producers providing quality information to describe and assess how well a dataset conforms to its product specification and to data users attempting to determine whether or not specific geographic data are of sufficient quality for their particular application.

This document does not attempt to define minimum acceptable levels of quality for geographic data. Such information is usually present as a requirement in a data product specification, defined in accordance with ISO 19131, for example.

2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

ISO 19103:2015, *Geographic information — Conceptual schema language*

ISO 19109:2015, *Geographic information — Rules for application schema*

ISO 19115-1:2014, *Geographic information — Metadata — Part 1: Fundamentals*

3 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

ISO and IEC maintain terminology databases for use in standardization at the following addresses:

- ISO Online browsing platform: available at <https://www.iso.org/obp>
- IEC Electropedia: available at <https://www.electropedia.org/>

3.1

accuracy

closeness of agreement between a test result or measurement result and the true value

Note 1 to entry: In this document, the true value can be a reference value that is accepted as true.

ISO 19157-1:2023(E)

[SOURCE: ISO 3534-2:2006, 3.3.1, modified — Notes 1, 2 and 3 to entry have been removed. A new Note 1 to entry has been added.]

3.2

conformance

conformity
fulfilment of a requirement

Note 1 to entry: When there is no ambiguity, the modifier “conformance” may be omitted. For example, “test report” is the same as “conformance test report”.

[SOURCE: ISO 19105:2022, 3.4]

3.3

conformance quality level

threshold value or set of threshold values for data quality results used to determine how well a dataset meets the criteria set forth in its data product specification or user requirements

3.4

correctness

correspondence with the universe of discourse

3.5

coverage

feature that acts as a function to return values from its range for any direct position within its domain

[SOURCE: ISO/FDIS 19123-1:—,¹⁾ 3.1.8]

3.6

data product specification

specification of a data product together with additional information that will enable it to be created, supplied to and used by another party

Note 1 to entry: A data product specification provides a description of the universe of discourse and a specification for mapping the universe of discourse to a data product. It may be used for production, sales, end-use or other purposes.

Note 2 to entry: A specification is a document stating requirements (see ISO 9000:2015, 3.8.7).

Note 3 to entry: A data product is a dataset or a dataset series that may be supplied (see ISO 19131:2022, 3.8),

[SOURCE: ISO 19131:2022, 3.9, modified — Notes 2 and 3 to entry have been added.]

3.7

data quality

degree to which a set of inherent characteristics of data fulfils requirements

[SOURCE: ISO 8000-2:2022, 3.8.1, modified — Note 1 to entry has been removed.]

3.8

data quality measure

variable to which a value is assigned as the result of measurement of a data quality characteristic

[SOURCE: ISO/IEC 25012:2008, 4.5, modified — Note 1 to entry has been removed.]

3.9

data quality unit

combination of a scope and data quality elements

1) Under preparation. Stage at the time of publication: ISO/FDIS 19123-1:2023.

3.10**dataset**

identifiable collection of data

Note 1 to entry: A dataset can be a smaller grouping of data which, though limited by some constraint such as spatial extent or *feature type*, is located physically within a larger dataset. Theoretically, a dataset can be as small as a single *feature* or *feature attribute* contained within a larger dataset. A hardcopy map or chart can be considered a dataset.

[SOURCE: ISO 19115-1:2014, 4.3]

3.11**dataset series**

collection of datasets sharing common characteristics

[SOURCE: ISO 19115-1:2014, 4.4]

3.12**feature**

abstraction of real world phenomena

Note 1 to entry: A feature can occur as a type or an instance. Feature type or feature instance will be used when only one is meant.

[SOURCE: ISO 19101-1:2014, 4.1.11]

3.13**feature attribute**

characteristic of a feature

Note 1 to entry: A feature attribute has a name, a data type and a value domain associated with it. A feature attribute for a feature instance also has an attribute value taken from the value domain.

[SOURCE: ISO 19101-1:2014, 4.1.12 modified — Examples 1 and 2, and Notes 2 and 3 to entry have been removed.]

3.14**feature instance**

individual of a given feature type having specified feature attribute values

[SOURCE: ISO 19101-1:2014, 4.1.14]

3.15**feature operation**

operation that every instance of a feature type may perform

[SOURCE: ISO 19110:2016, 3.7, modified — Example and Note 1 to entry have been removed.]

3.16**feature type**

class of features having common characteristics

[SOURCE: ISO 19156:2011, 4.7]

3.17**geographic data**

data with implicit or explicit reference to a location relative to the Earth

[SOURCE: ISO 19109:2015, 4.13, modified — Note 1 to entry has been removed.]

3.18

item

anything that can be described and considered separately

Note 1 to entry: An item can be any part of a *dataset*, such as a *feature*, feature relationship, *feature attribute*, or combination of these.

[SOURCE: ISO 2859-5:2005, 3.4, modified — Example has been removed. Note 1 to entry has been added.]

3.19

lineage

provenance, source(s) and production process(es) used in producing a resource

[SOURCE: ISO 19115-1:2014, 4.9]

3.20

metadata

information about a resource

[SOURCE: ISO 19115-1:2014, 4.10]

3.21

metaquality

information describing the quality of data quality

3.22

quality

degree to which a set of inherent characteristics of an object fulfils requirements

[SOURCE: ISO 9000:2015, 3.6.2, modified — Note 1 and 2 to entry have been removed.]

3.23

quality evaluation

systematic examination of the extent to which an entity is capable of fulfilling specified requirements

[SOURCE: ISO/IEC/IEEE 24765:2017, 3.3267, modified — Note 1 to entry has been removed.]

3.24

register

set of files containing identifiers assigned to items with descriptions of the associated items

[SOURCE: ISO 19135-1:2015, 4.1.9]

3.25

requirement

need or expectation that is stated, generally implied or obligatory

[SOURCE: ISO 9000:2015, 3.6.4, modified — Notes 1-6 to entry have been removed.]

3.26

quality evaluation report

quality report

free text document providing fully-detailed information about data quality evaluations, results and measures used

3.27**uncertainty**

measurement uncertainty

parameter, associated with the result of measurement, that characterizes the dispersion of values that could reasonably be attributed to the measurand

Note 1 to entry: Uncertainty of measurement comprises, in general, many components. Some of these components may be evaluated from the statistical distribution of the results of series of measurements and can be characterized by experimental standard deviations. The other components, which can also be characterized by standard deviations, are evaluated from assumed probability distributions based on experience or other information.

[SOURCE: ISO 19116:2019, 3.28, modified — Note 1 to entry has been removed and replaced with Note 2 to entry from ISO 19101-2:2018, 3.40.]

3.28**universe of discourse**

view of the real or hypothetical world that includes everything of interest

[SOURCE: ISO 19101-1:2014, 4.1.38]

4 Abbreviated terms and packages**4.1 Abbreviated terms**

ADQR aggregated data quality result

AQL acceptance quality limit

GML Geographic Markup Language

UML Unified Modelling Language

XML Extensible Markup Language

4.2 Abbreviated packages

Abbreviations are used to denote the package that contains a class. Those abbreviations precede class names, connected by a "_". A list of those abbreviations is listed in [Table 1](#). The International Standard in which the classes are located is indicated in parentheses.

Table 1 — Package abbreviations

CI	Citation [ISO 19115-1:2014]
DS	Dataset [ISO 19115-1:2014]
GF	General Feature [ISO 19109:2015]
LI	Lineage [ISO 19115-1:2014]
MD	Metadata [ISO 19115-1:2014]

5 Conformance**5.1 General**

In this document two conformance classes are defined (see [5.2](#) and [5.3](#)). The related tests are provided in the abstract test suit in [Annex A](#).

Requirements, recommendations and permissions are explicitly marked and assigned a requirement, recommendation or permission identifier.

The name and contact information of the maintenance agency for this document can be found at www.iso.org/maintenance_agencies.

5.2 Content of a data quality model

[Table 2](#) describes the conformance class for the content of a data quality definition.

Table 2 — Content conformance class

Conformance class	https://standards.iso211.org/19157/-1/1/conf/content
Standardization target type	Instance of a data quality definition, regardless of data encoding.
Dependency	https://standards.iso211.org/19103/2/1/ (Conceptual schema language) https://standards.iso211.org/19109/-/2/ (Rules for application schema) https://standards.iso211.org/19115/-1/1/ (Metadata – Part 1: Fundamentals)
Requirements class	https://standards.iso211.org/19157/-1/1/req/content (see Clause 6)
Tests	All tests in Clause A.1 .

5.3 XML encoding of a data quality model

[Table 3](#) describes the conformance class for the XML representation of a data quality model.

Table 3 — XML encoding conformance class

Conformance class	https://standards.iso211.org/19157/-1/1/conf/xml
Standardization target type	XML document representing a data quality model.
Dependency	https://standards.iso211.org/19157/-1/1/conf/content
Requirements class	https://standards.iso211.org/19157/-1/1/req/xml (see Clause 12)
Tests	All tests in Clause A.2 .

6 General requirements for geographic information quality

6.1 General

[Clauses 8](#) to [11](#) describe the components of data quality based on the conceptual Unified Modelling Language (UML) model defined in this document, which is part of the ISO/TC 211 harmonized model. Furthermore, additional descriptions, requirements and recommendations are included. A dictionary of elements in the UML model is provided in [Annex C](#).

The requirements, recommendations and permissions defined in this document are summarized in [Tables 4, 5](#) and [6](#).

6.2 Data quality — general requirements, recommendations and permissions

[Table 4](#) lists the requirements defined in this document.

Table 4 — List of requirements

Requirement class	https://standards.iso211.org/19157/-/1/req/content
Standardization target type	Instance of a data quality definition regardless of data encoding.
Dependency	https://standards.iso211.org/19103/-/1/ (Conceptual schema language)
Dependency	https://standards.iso211.org/19109/-/2/ (Rules for application schema)
Dependency	https://standards.iso211.org/19115/-/1/1/ (Metadata — Part 1: Fundamentals)
Requirement 1	https://standards.iso211.org/19157/-/1/1/req/content/dataQuality
Requirement 2	https://standards.iso211.org/19157/-/1/1/req/content/additionalQualityElement
Requirement 3	https://standards.iso211.org/19157/-/1/1/req/content/qualityMeasure
Requirement 4	https://standards.iso211.org/19157/-/1/1/req/content/additionalQualityMeasure
Requirement 5	https://standards.iso211.org/19157/-/1/1/req/content/dataQualityMetadata
Requirement 6	https://standards.iso211.org/19157/-/1/1/req/content/qualityEvaluationReport
Requirement 7	https://standards.iso211.org/19157/-/1/1/req/content/aggregatedResult
Requirement 8	https://standards.iso211.org/19157/-/1/1/req/xml

In addition to the requirements class in [Table 4](#), a recommendations class is defined in [Table 5](#) and a permission class is defined in [Table 6](#). These recommendations and permissions, when implemented, can contribute to improved content of a data quality definition. However, recommendations and permissions are optional and do not have an impact on the results of the conformance testing; thus the recommendation class in [Table 5](#) and the permission class defined in [Table 6](#) are not related to any of the conformance classes defined in [Clause 4](#).

Table 5 — List of recommendations

Recommendation class	https://standards.iso211.org/19157/-/1/1/req/optionalContent
Standardization target type	Instance of a data quality definition regardless of data encoding.
Dependency	https://standards.iso211.org/19157/-/1/1/req/content
Recommendation 1	https://standards.iso211.org/19157/-/1/1/rec/optionalContent/dateTime
Recommendation 2	https://standards.iso211.org/19157/-/1/1/rec/optionalContent/identifier
Recommendation 3	https://standards.iso211.org/19157/-/1/1/rec/optionalContent/additionalQualityMeasure
Recommendation 4	https://standards.iso211.org/19157/-/1/1/rec/optionalContent/description
Recommendation 5	https://standards.iso211.org/19157/-/1/1/rec/optionalContent/qualityEvaluationProcess
Recommendation 6	https://standards.iso211.org/19157/-/1/1/rec/optionalContent/evaluationMethodType
Recommendation 7	https://standards.iso211.org/19157/-/1/1/rec/optionalContent/reportReference
Recommendation 8	https://standards.iso211.org/19157/-/1/1/rec/optionalContent/aggregatedResult

Permission 3	https://standards.isotc211.org/19157/-1/1/per/permittedContent/sourceReference

7 Overview of data quality

Working with data quality includes the following points.

- Understanding the concepts of data quality related to geographic data. [Annex B](#) provides a description of data quality concepts used to establish the components for describing the quality of geographic data.
- Defining data quality conformance levels in data product specifications or based on user requirements. Establishment of data product specifications is described in ISO 19131.
- Specifying quality aspects in application schemas.
- Evaluating data quality and metaquality.
- Reporting data quality and metaquality.

NOTE 1 The development of application schemas is described in ISO 19109.

A data quality evaluation can be applied to a dataset series, a dataset or a subset of data within a dataset sharing common characteristics so that its quality can be evaluated.

Data quality elements and their descriptors are used to describe how well a dataset meets the criteria set forth in its data product specification or user requirements and provide quantitative quality information.

Requirement 1:	https://standards.isotc211.org/19157/-1/1/req/content/dataQuality
	Data quality shall be described in conformance with the components of data quality and data quality measures as defined by the UML figures in Clauses 8 and 9 of this document.

When data quality information describes data that have been created without a detailed data product specification or with a data product specification that lacks quantitative measures and descriptors, data quality may be evaluated in a non-quantitative subjective way with a descriptive result (see [8.5.4.4](#)) used to report the evaluation result for each of the applicable data quality elements.

Some quality-related information is provided by purpose, usage and lineage. This information is reported as metadata in conformance with ISO 19115-1.

NOTE 2 'Purpose' describes the rationale for creating a dataset and contains information about its intended use, which can potentially be not the same as the actual use of the dataset. 'Usage' describes the application(s) for which a dataset has been used, either by the data producer or by other data users. 'Lineage' describes the history of a dataset and recounts the life cycle of a dataset from collection and acquisition through compilation and derivation to its current form. This general, non-quantitative information is illustrative for users and can help in assessing the quality of a dataset, especially in cases where it is used for a particular application that differs from the intended application (see also [10.2.3](#)).

This document recognizes that data quality elements may have associated quality which is termed metaquality. Metaquality describes the quality of the data quality results in terms of defined characteristics.

NOTE 3 The concept of metaquality is described in [8.3.7](#) and the descriptors of metaquality are defined in [8.5.5](#).

[Figure 1](#) provides an overview of data quality information.

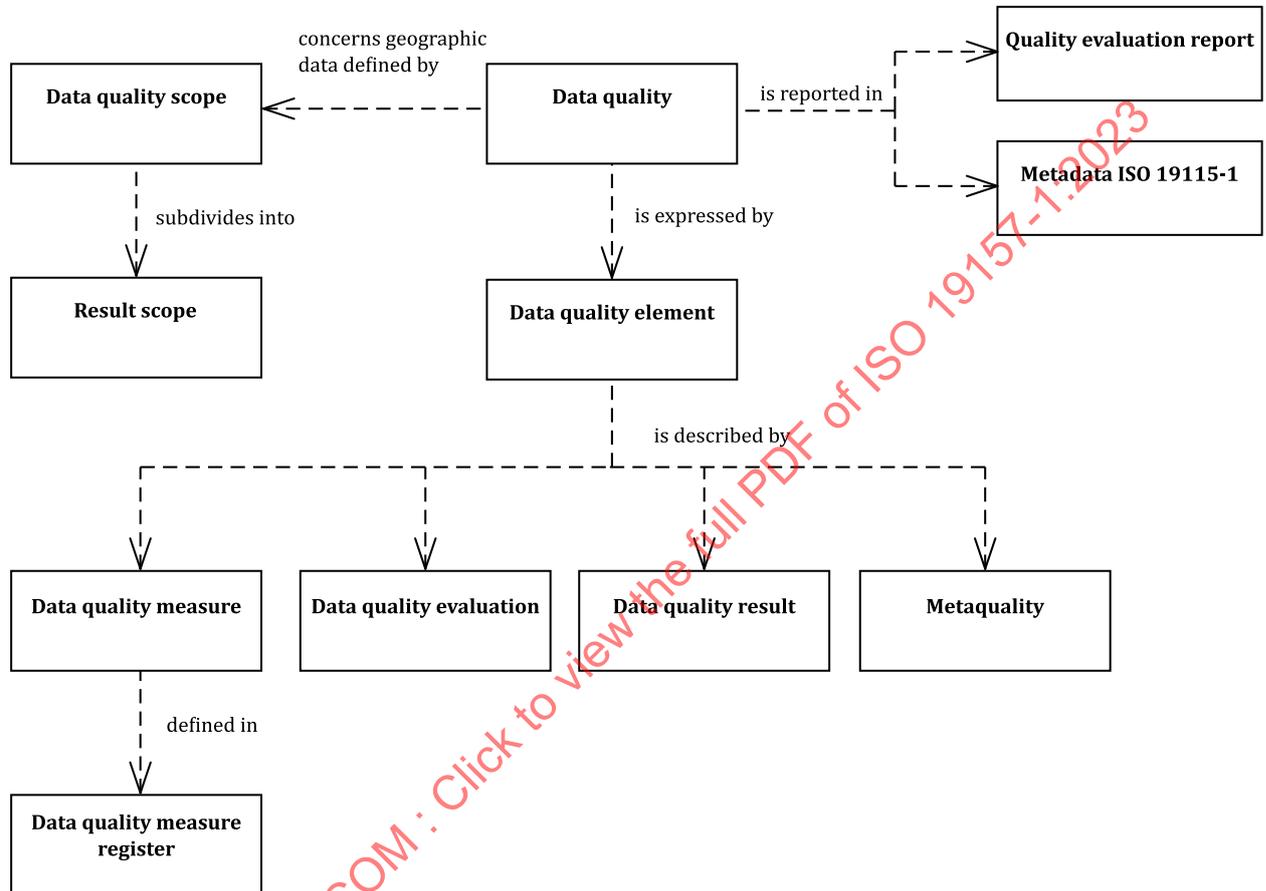

Figure 1 — Conceptual model of quality for geographic data

8 Components of data quality

8.1 Overview of the components

The components of data quality are described in [Clause 8](#). [Figure 2](#) presents an overview of the components and the connections between them. See the data dictionary defined in [Annex C](#) for more details about components and their attributes.

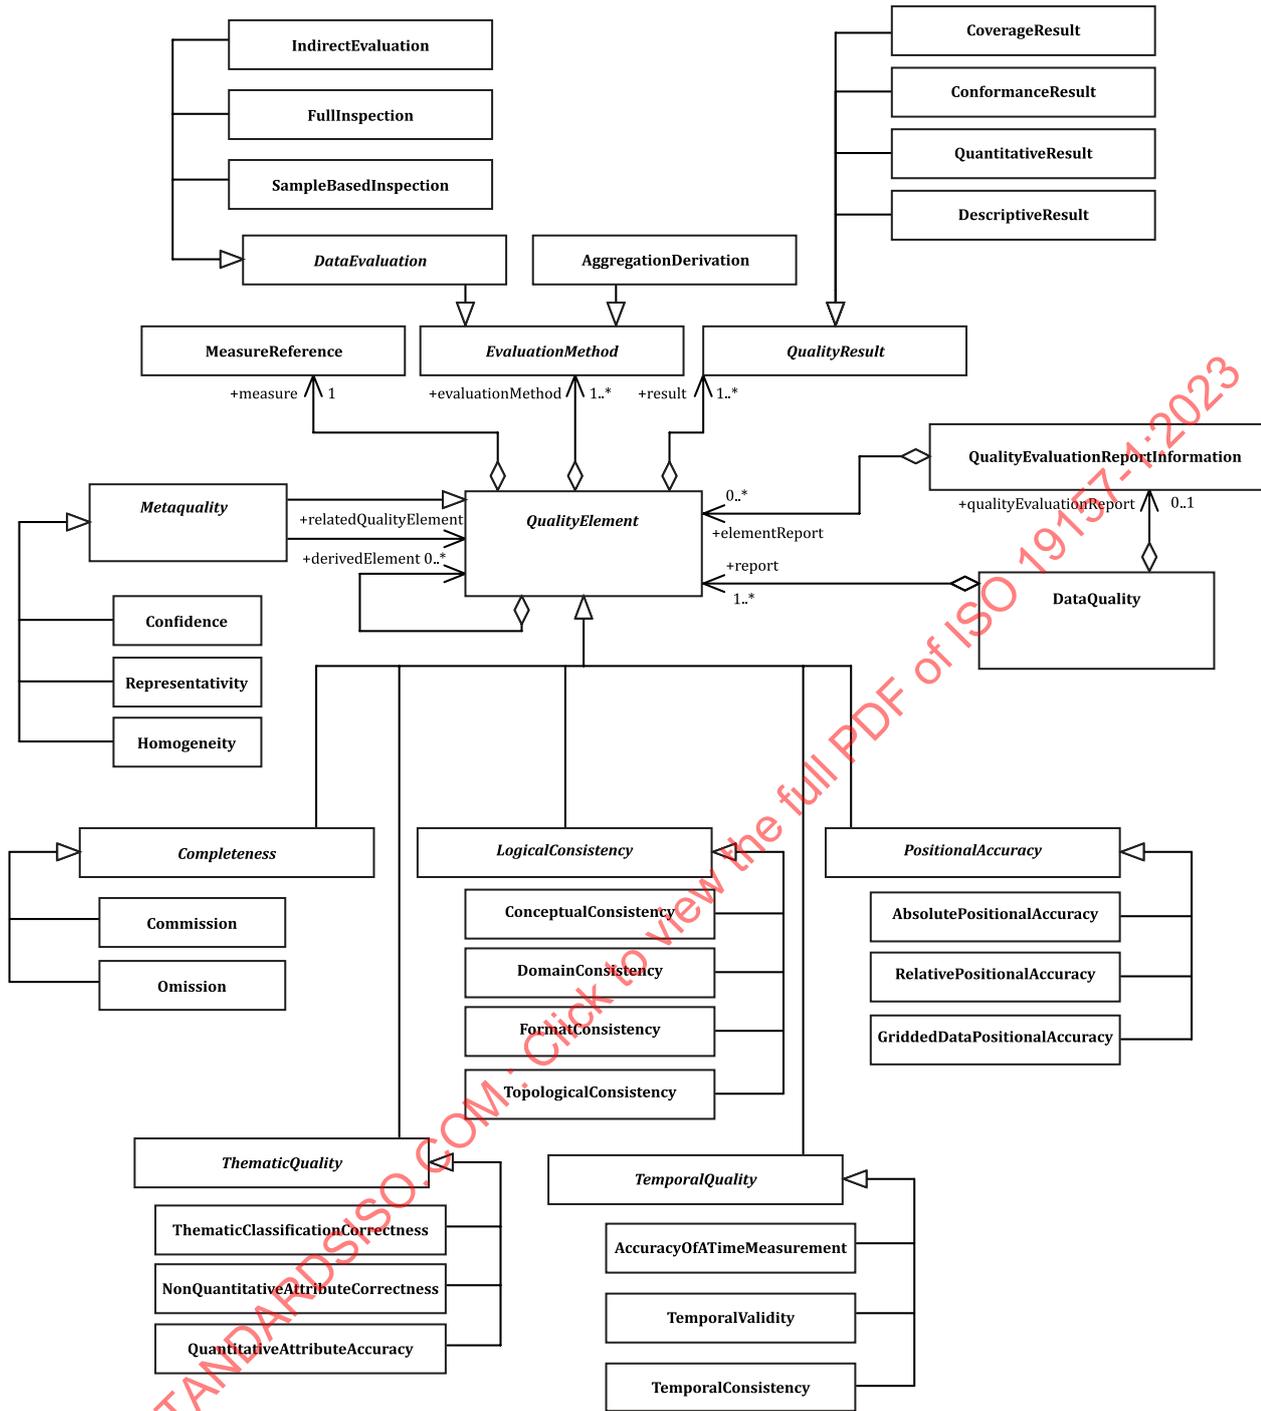

Figure 2 — Overview of the components of data quality

8.2 Data quality unit

When describing the quality of geographic data, different quality elements and different subsets of the data may be considered. In order to describe these, data quality units are used. A data quality unit is the combination of a scope and data quality elements; see [Figure 3](#) and [Table C.1](#).

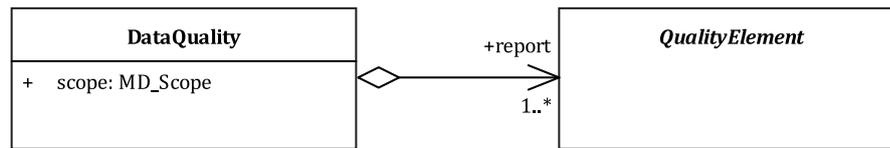

Figure 3 — Data quality unit

The scope of the data quality unit(s) specifies the extent, spatial and/or temporal, and/or common characteristic(s) that identify the data on which data quality is to be established and evaluated.

Since scopes are often different for individual data quality elements, one data quality report (metadata or quality evaluation report) may encompass several data quality units. These different scopes may be, for example, spatially separate, overlapping or even sharing the same extents.

NOTE If a dataset is a result of integration of datasets of various scopes, data quality values or weights of quality elements, such a new dataset needs to establish its new data quality unit, i.e. define its own data quality scope and specify quality elements of interest.

The following are examples of what defines a data quality scope (see also MD_Scope in ISO 19115-1):

- a) a dataset series;
- b) a dataset;
- c) a subset of data defined by one or more of the following characteristics:
 - 1) types of items (sets of feature types, feature attributes, feature operations or relationships among features),
 - 2) specific items (sets of feature instances, attribute values or instances of feature relationships),
 - 3) geographic extent,
 - 4) temporal extent (the time frame of reference and accuracy of the time frame);
- d) a coverage.

8.3 Data quality elements

8.3.1 General

A data quality element is a component describing a certain aspect of the quality of geographic data. In this document, these have been organized into groups of quality elements, with each group defined in 8.3.2 to 8.3.7. The relationship among various aspects of quality and their corresponding quality elements are illustrated in Figure 4, where groups of elements are represented by abstract classes and elements are represented by their subclasses.

NOTE Depending on the tool used and/or organizational preferences, implementations of the data quality conceptual model presented in Figure 4 vary. Advising on best implementation practice is out of the scope of this document.

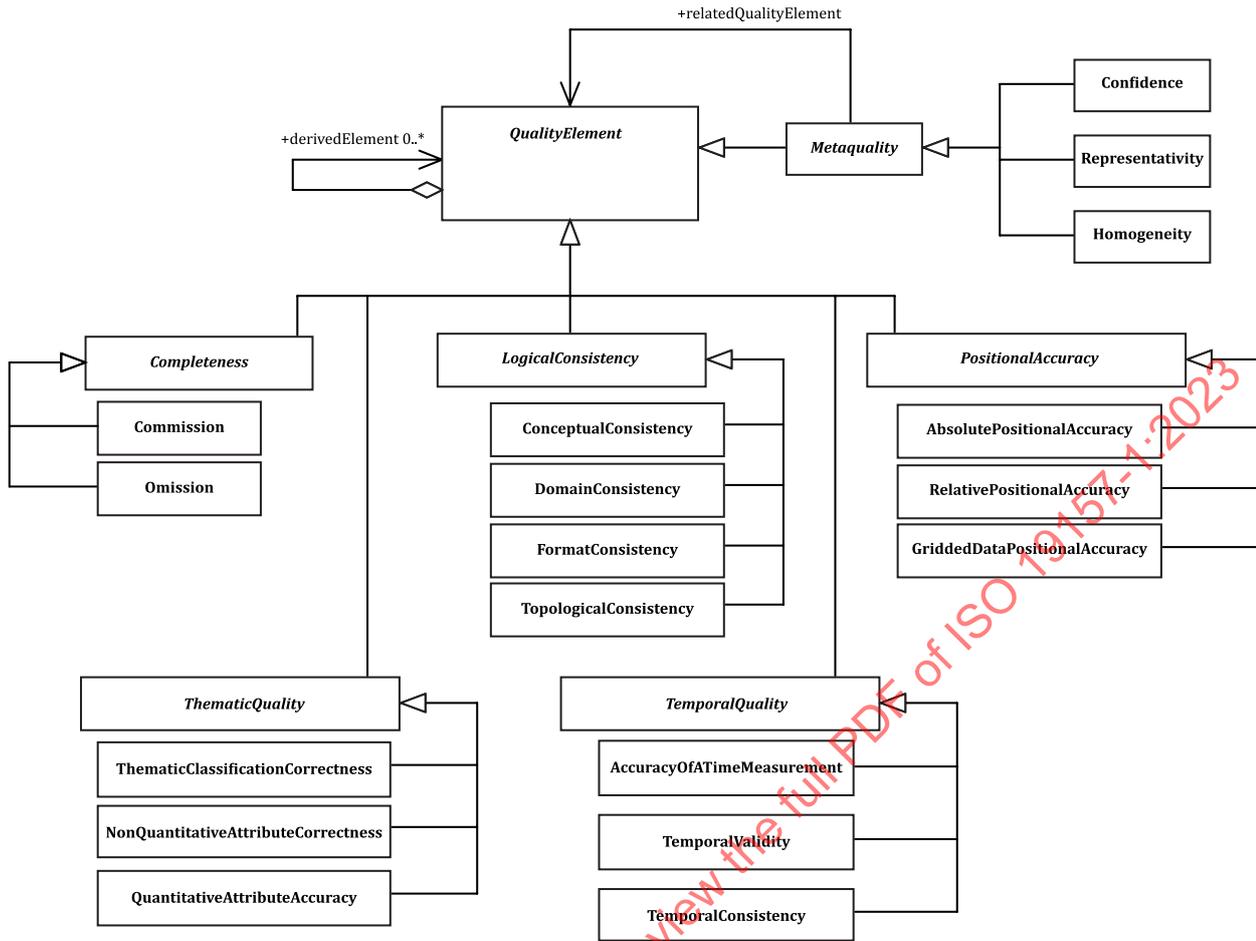

Figure 4 — Overview of the data quality elements

Permission 1:	<p>https://standards.iso/211.org/19157/-1/1/per/permittedContent/additionalQualityElement</p> <p>If quality elements defined in this document are not sufficient for expressing the quality of the dataset, new elements can be defined and used according to the requirements specified in 8.4.</p>
---------------	---

8.3.2 Completeness

Completeness is defined as a degree to which a dataset (or dataset series) representing a feature (or features) has values for all expected attributes and related entity instances at the time at which the dataset has been created (ISO 8000-2; ISO/IEC 25012). As such, completeness refers to the presence and/or absence of features, their attributes and relationships. In this document, two elements (and their associated measures) define completeness:

- commission: excess data present in a dataset;
- omission: data absent from a dataset.

8.3.3 Logical consistency

Logical consistency is defined as the degree of adherence to logical rules of data structure, attribution and relationships (data structure can be conceptual, logical or physical). If these logical rules are documented elsewhere (for example, in a data product specification) then the source should be

referenced (for example, in the data quality evaluation). This document specifies logical consistency with data quality elements (and their associated measures):

- conceptual consistency: adherence to rules of the conceptual schema;
- domain consistency: adherence of values to the value domains;
- format consistency: degree to which data are stored in accordance with the physical structure of the dataset;
- topological consistency: correctness of the explicitly encoded topological characteristics of a dataset.

8.3.4 Positional accuracy

Positional accuracy relates to measurement accuracy (ISO/IEC Guide 98-3; ISO/IEC Guide 99) and it represents a closeness of agreement between a measured position of features and a position accepted as true within a spatial reference system. Depending on the scope and type of the reference system, this document specifies the following three data quality elements for expressing positional accuracy:

- absolute or external accuracy: closeness of reported coordinate values to values accepted as true in a standard coordinate reference system;
- relative or internal accuracy: closeness of the relative positions of features in a related dataset to their respective relative positions accepted as true in a local coordinate reference system;
- gridded data positional accuracy: closeness of gridded data spatial position values to values accepted as true.

Positional accuracy is an estimate of the uncertainty of measurement results (ISO 19116) and should therefore be expressed with measures of uncertainty.

8.3.5 Temporal quality

Temporal quality is defined as the quality of the temporal attributes and temporal relationships of features. Temporal quality can be described by the following data quality elements (and their associated measures):

- accuracy of a time measurement: closeness of reported time measurements to values accepted as true;
- temporal consistency: correctness of the order of events.
- temporal validity: validity of data with respect to time.

NOTE 1 Timeliness, currentness (ISO/IEC 25012), up-to-dateness and actuality are used as synonyms for temporal validity.

NOTE 2 Temporal validity is different from domain consistency of temporal values. For example, a value of '33 March 2020' representing a date indicates a domain inconsistency. An example of temporal invalidity is a dataset that contains objects that did not exist in the timestamp associated with their record.

8.3.6 Thematic quality

Thematic quality is defined as the accuracy of quantitative attributes and the correctness of non-quantitative attributes and of the classifications of features and their relationships. This document specifies thematic quality with three data quality elements (and their associated measures):

- classification correctness: comparison of the classes assigned to features or their attributes to a universe of discourse (e.g. ground truth or reference data);

- non-quantitative attribute correctness: measure of whether a non-quantitative attribute is correct or incorrect;
- quantitative attribute accuracy: closeness of the value of a quantitative attribute to a value accepted as or known to be true.

8.3.7 Metaquality elements

Metaquality elements are a set of quantitative and qualitative statements about a quality evaluation and its result. The knowledge about the quality and the suitability of the evaluation method, the measure applied, and the given result may be of the same importance as the result itself.

See [D.5.3](#) for an example of metaquality evaluation.

Metaquality should be described using the following elements.

- Confidence: trustworthiness of a data quality result.

NOTE 1 Quantitative figures for confidence can be obtained by statistical parameters such as standard deviation or a confidence interval on a given confidence level.

EXAMPLE Confidence originates primarily from the method used and its reliability, as well as, to a lesser extent, from the concerned population.

- Representativity: degree to which the sample used has produced a result which is representative of the data within the data quality scope.

NOTE 2 A statistical method based on sampling could be considered as reliable as a global method when all the geographic zones and concerned time periods are covered and the population is sufficiently large. It is not only the size of the sample which is crucial but also how well it represents the actual state of the data. See also [10.2.2](#) and [Annex E](#).

- Homogeneity: expected or tested uniformity of the results obtained for a data quality evaluation.

NOTE 3 Homogeneity consists of comparing the evaluation results of several segments of a global dataset. This comparison can be expressed using root mean square errors for example (as in [E.5.3](#)). In the case of a general process, homogeneity cannot be evaluated because the result is global.

NOTE 4 These tests are often conducted when data has been captured by different operators, depending on the acquisition zone or the acquisition date.

8.4 Extending the data quality information model

This document recognizes that for many domain-specific purposes, it is necessary or convenient to extend the standard data quality information model as defined in [8.3](#). The extension includes adding data quality elements (or one of its specializations as defined in [8.3](#)) and data quality measures.

EXAMPLE Data producers can wish to provide means for their users to record feedback on a dataset. As an example, an information model for such feedback (i.e. new quality elements) can be defined with elements from Reference [\[36\]](#).

Requirement 2:	<p>https://standards.iso/2023/19157-1/1/req/content/additionalQualityElement</p> <p>A new quality element shall be defined as a specialization of <i>QualityElement</i>, (see 8.3) in conformance with the rules for metadata extensions (ISO 19115-1:2014, Annex C) and rules for domain profiles of standard schemas (ISO 19109:2015, 8.3).</p> <p>NOTE If applicable, elements defined in other International Standards (e.g. ISO/IEC 25000) can be used for extending the set of quality components as defined in Clause 8.</p>
----------------	---

8.5 Descriptors of data quality elements

8.5.1 General

A data quality element is described by a reference to a quality measure, an evaluation method, quality result and a metaquality element. These are shown in [Figure 5](#), and are described in [8.5.2](#) to [8.5.5](#).

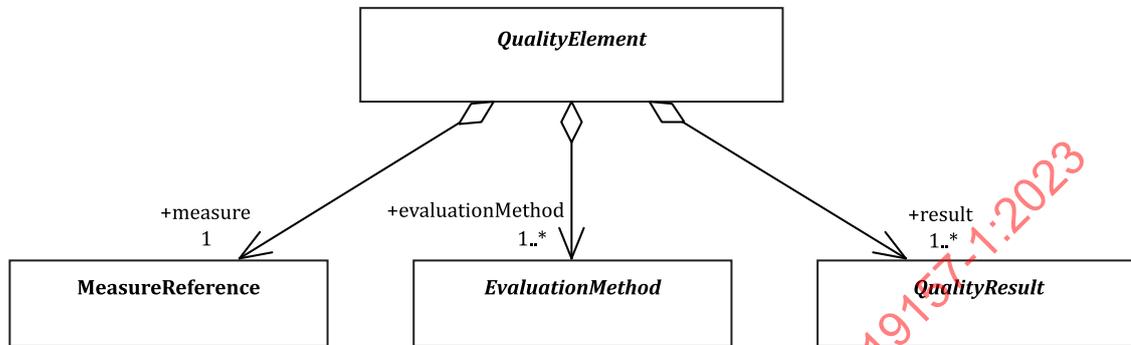

Figure 5 — Data quality element descriptors

8.5.2 Measure reference

Data quality elements refer to measures by means of a measure reference (see [Figure 6](#)), providing an identifier of a measure fully described elsewhere.

NOTE The full description can be found within a measure register or catalogue, which can form part of a data product specification or a quality evaluation report.

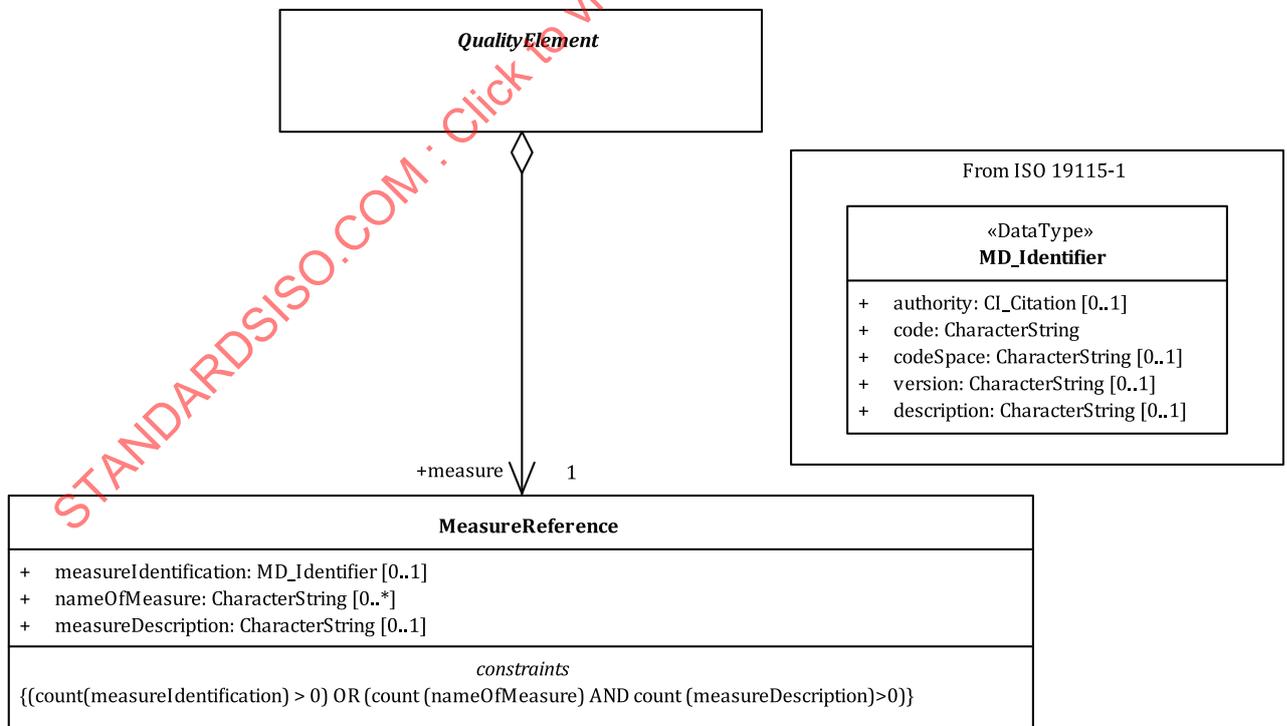

Figure 6 — Data quality measure reference

Data quality measures are further described in [Clause 9](#) of this document.

EXAMPLE The percentage of the values of an attribute which are correct.

This document recognizes that the quality of a dataset is measured using a variety of methods. A single data quality measure can be insufficient for fully evaluating the quality of the data specified by a data quality scope and providing a measure of quality for all possible utilizations of a dataset. A combination of data quality measures can give useful information. Multiple data quality measures may be reported for the data specified by a data quality scope. The data quality report should then include one instance of *QualityElement* for each measure applied.

8.5.3 Evaluation method

A data quality evaluation method describes those procedures and methods which are applied to the geographic data to arrive at a data quality result; see [Figure 7](#). Different evaluations are often used for the various data quality elements.

A data quality evaluation method is used for describing, or for referencing documentation describing, the methodology used to apply a data quality measure to the data specified by a data quality scope.

NOTE Data quality evaluation is further described in [Clause 10](#).

EXAMPLE Examples of documentation are data product specifications (e.g. ISO 19131), published articles or accepted industry standards.

Recommendation 1:	https://standards.iso211.org/19157/-1/1/rec/optionalContent/dateTime One date or range of dates (conforming to ISO 19108) should be included for each evaluation. If the evaluation was carried out on non-consecutive dates, each single date should be included.
-------------------	--

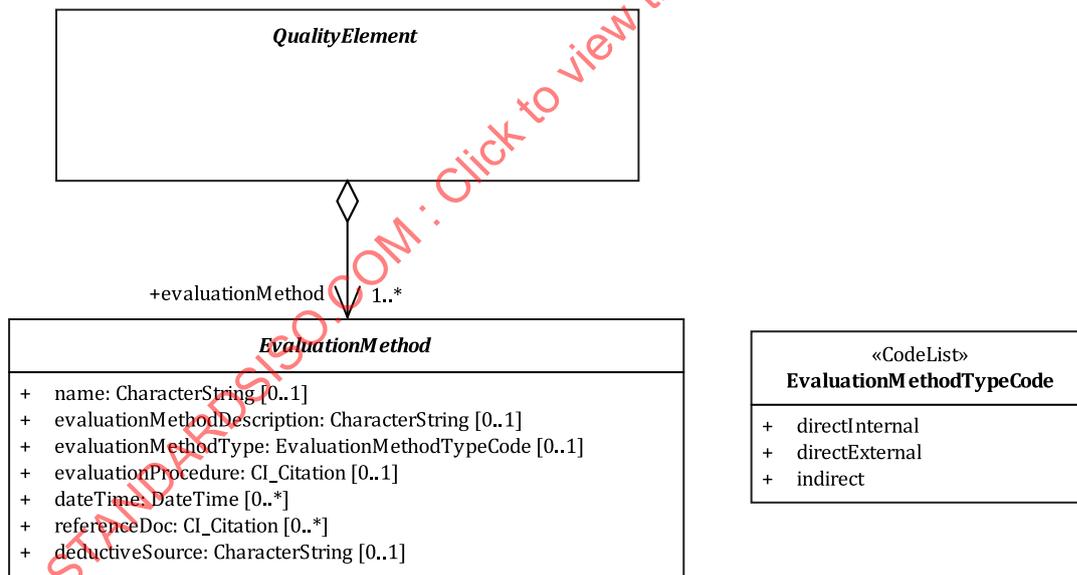

Figure 7 — Data quality evaluation method

8.5.4 Quality result

8.5.4.1 General

A data quality result is provided for each data quality element. This can be a quantitative result, a conformance result, a descriptive result or a coverage result; see also [Figure 8](#).

NOTE Different types of results can be provided for the same data quality element.

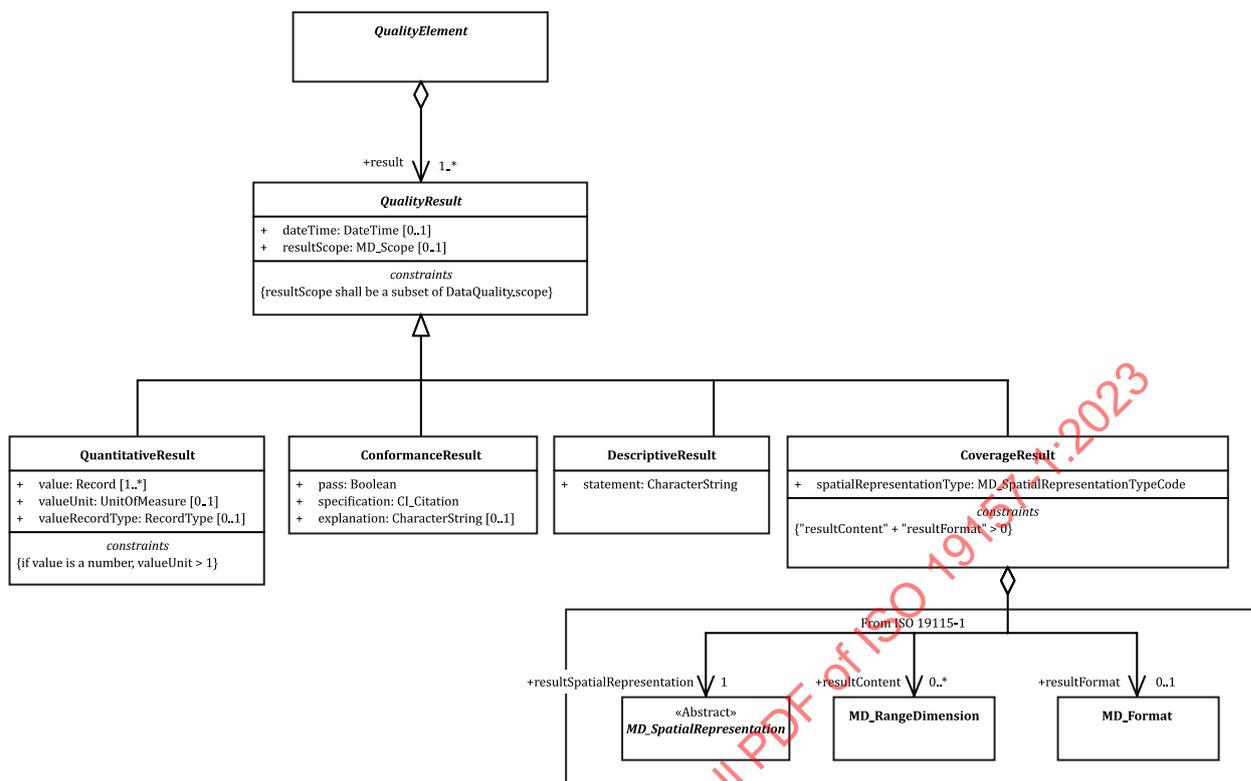

Figure 8 — Data quality result

Quality frequently differs between various parts of the dataset for which quality is evaluated. Therefore, several evaluations may be applied for the same data quality element to more fully and in more detail describe quantitative data quality. To avoid repeating the measure and evaluation procedure descriptions in several instances of data quality element (*QualityElement*), several results with individual result scopes can be used.

EXAMPLE A dataset contains features of identical type but whose positions have been established with various methods yielding different positional accuracies. The same quality evaluation method and the same measure are, however, applied for the whole dataset, and provide different results depending on the data acquisition method. In this case, it can be desirable to have several results with individual result scopes (the area covered by each data acquisition method) and one data quality scope (the dataset).

8.5.4.2 Quantitative result

A quantitative result may be a single value or multiple values, depending on the values of attributes *valueType* and *valueStructure* defined in the description of the measure applied.

The attribute *valueRecordType* is used to describe how the *valueType* and *valueStructure* defined in the measure are implemented to provide the value of the quantitative result.

NOTE The attribute *valueRecordType* is of type *RecordType*, which is a generic data type defined in ISO 19103. Its value changes depending on which implementation solution is used for providing the quantitative result. An example of Extensible Markup Language (XML) implementation for *recordType* is provided in ISO/TS 19139-1.

EXAMPLE 1 Using an XML implementation: simple example: value = 5, valueRecordType = gco:Integer, valueUnit = "metre."

EXAMPLE 2 Within the description of the measure, the *valueType* is an integer, the *valueStructure* is an $n \times n$ (square) matrix. The *value* attribute of the quantitative result provides the result matrix itself, within a numeric encoding using a particular XML type called *MatrixType*. The attribute *valueRecordType* provides the description of the type *MatrixType* in XML. If another encoding is used, the attribute *valueRecordType* will change to provide the description of the type *Matrix* in the other encoding, and the implementation of the attribute *value* will change accordingly, but the value itself will not change.

EXAMPLE 3 Measure “Rate of excess items” is used to evaluate the number of excess items in the dataset in relation to the number of items that are expected to be present. The quantitative result value is of value type Real. The value unit is used in this case to show that the value is a percentage; the value has been multiplied by 100. In this example the value unit is “%”.

8.5.4.3 Conformance result

A conformance result is the outcome of comparing the value or set of values obtained from applying a measure to the data specified by a data quality scope with a specified conformance quality level (e.g. as recorded in an ISO 19131-conformant data product specification).

When a conformance quality level is defined, the obtained result is compared with this to evaluate if the quality of the data meets the specified level of quality.

A conformance result may be provided for each measure. The conformance quality level is typically specified in suitable reference documentation such as the data product specification (e.g. an ISO 19131-conformant data product specification) or a user-defined requirements specification. If conformance is evaluated, a reference to the relevant reference documentation shall be made and the conformance quality level used shall be specified.

The conformance result is not to be used for specifying the conformance quality level in an ISO 19131-conformant data product specification.

Recommendation 2:	https://standards.iso211.org/19157/-1/1/rec/optionalContent/identifier An <i>identifier</i> should be provided for the <i>specification</i> attribute of <i>ConformanceResult</i> . NOTE <i>specification</i> is of type <i>CI_Citation</i> , in which, as defined by ISO 19115-1, the <i>identifier</i> is optional.
-------------------	--

Permission 2:	https://standards.iso211.org/19157/-1/1/per/permittedContent/conformanceResult If an evaluation has been performed against conformance levels originating from different sources, more than one data quality <i>ConformanceResult</i> may be provided for the same measure.
---------------	---

8.5.4.4 Descriptive result

In some cases (e.g. with thematic and geoscientific observations), it is not possible to produce a quantitative result for a data quality element. A subjective evaluation of an element can then be expressed with a textual statement as a data quality descriptive result.

EXAMPLE The relative positional accuracy is higher between a geological feature and a nearby feature from a base map (roads, rivers, lakes etc.) than the absolute positional accuracy on the geological feature itself.

This descriptive result can also be used to provide a short synthetic description of the result of the data quality evaluation, to accompany the complete quantitative result or replace it, if no quantitative value can be provided.

8.5.4.5 Coverage result

A data quality result can be provided as information in a coverage. A UML model for a coverage result is provided in [Figure 8](#).

8.5.5 Descriptors of a metaquality element

A metaquality element is described by the same descriptors as for the quality element: measure, evaluation method and result (see Figure 9).

NOTE The related quality element is the element on which the metaquality element applies.

See E.5.3 for an example of metaquality evaluation.

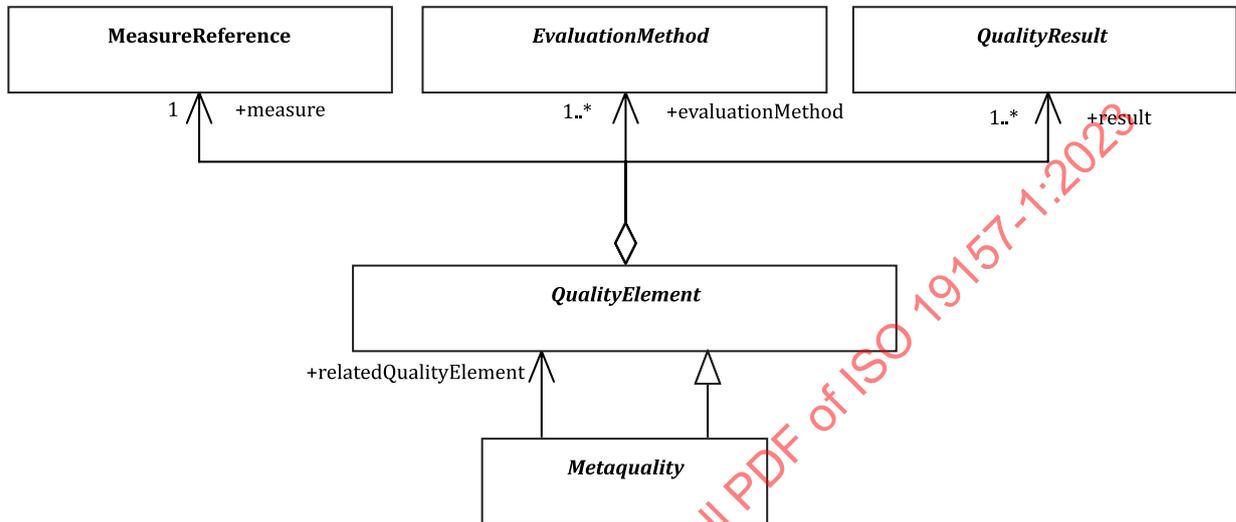

Figure 9 — Metaquality descriptors

9 Data quality measures

9.1 General

To facilitate dataset comparisons, evaluations and data quality reports (metadata or a quality evaluation report) have to be expressed in a comparable way, and it is necessary to have a common understanding of the data quality measures that have been used.

Requirement 3:	<p>https://standards.iso.org/19157/-1/1/req/content/qualityMeasure</p> <p>When possible, measures defined in a quality measures register for geographic information shall be used in data quality evaluations and to represent the result of the quality evaluation in quality evaluation reports and metadata.</p> <p>NOTE 1 If no measure as defined in a quality measures register for geographic information is applicable, additional, user-defined measures can be used (see 9.3).</p> <p>NOTE 2 Elements defined in other International Standards (e.g. ISO/IEC 25000) can be used for extending the quality model, if applicable.</p>
----------------	---

9.2 Standardized data quality measures

9.2.1 General

The structure of standard data quality measures is illustrated in Figure 10.

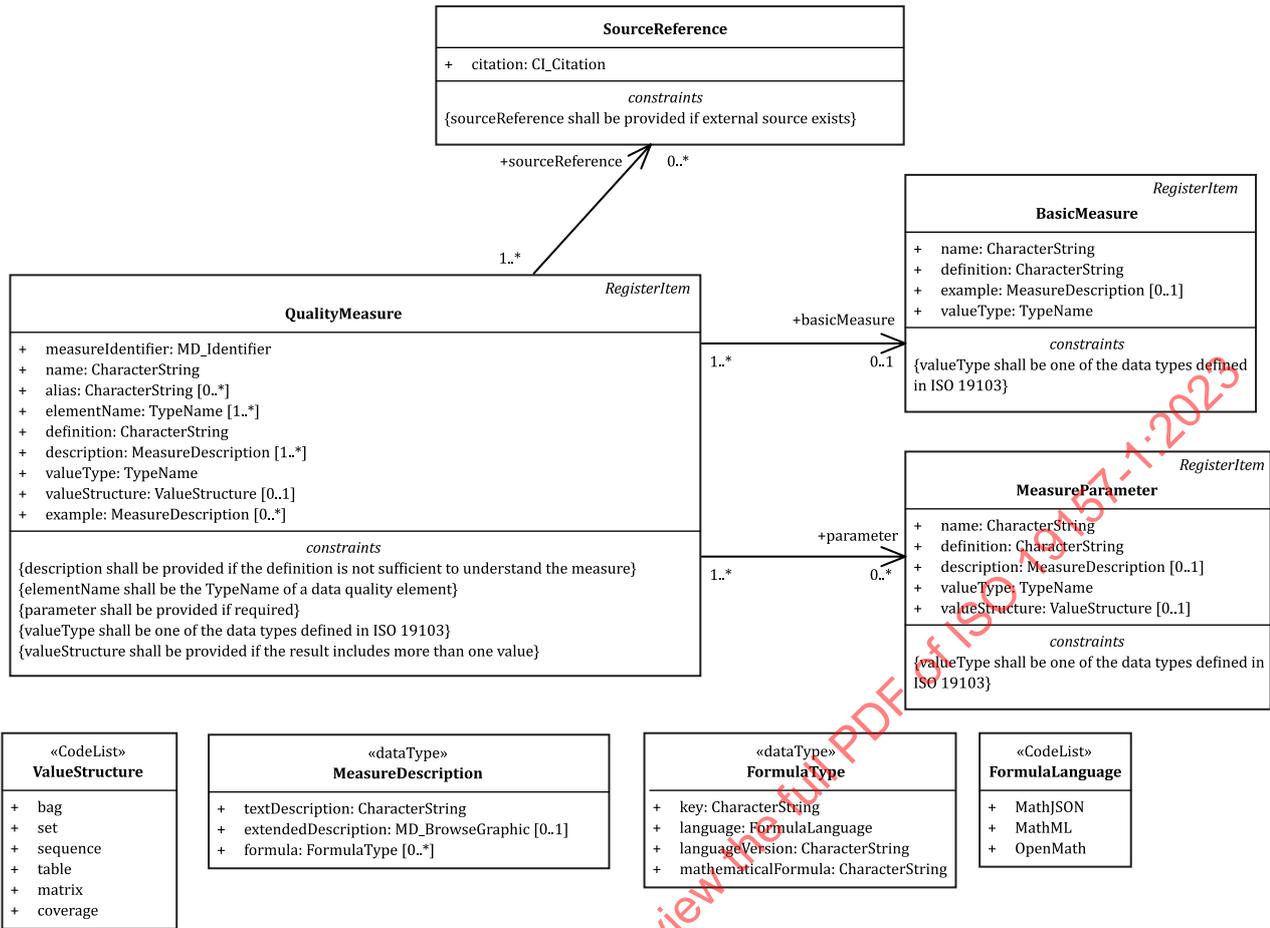

Figure 10 — Data quality measures

Each data quality measure is described by the following components:

- measure identifier (9.2.2);
- name (9.2.3);
- alias (9.2.4);
- element name (9.2.5);
- basic measure (9.2.6);
- definition (9.2.7);
- description (9.2.8);
- parameter (9.2.9);
- value type (9.2.10);
- value structure (9.2.11);
- source reference (9.2.12);
- example (9.2.13).

Multiple measures can be defined for each data quality element. The choice of which one to use will depend on the type of the data and its intended purpose. A list of standardized data quality measures is given in a data quality measure register defined in conformance with ISO 19135-1.

9.2.2 Measure identifier

The identifier is a value uniquely identifying a measure within a namespace.

NOTE This identifier enables references to the data quality measure within the data quality elements (see [8.5.2](#)).

9.2.3 Name

The name is the name of the measure.

NOTE If the measure already has a commonly used name, this name is be used. If no name exists, a name that reflects the nature of the measure is chosen.

9.2.4 Alias

The alias is another recognized name for the same data quality measure. It may be a different commonly-used name, or an abbreviation, or a short name. More than one alias may be provided.

9.2.5 Element name

The element name is the name of the data quality element (see [8.3](#) and [8.4](#)) to which a measure applies. More than one element name may be provided.

9.2.6 Basic measure

Basic measures are defined by their *name*, *definition*, *example* and *valueType* (see [Figure 10](#)).

The basic measures should also be used for creating new measures if applicable. For example, to report unclosed surface patches or other application-dependent measures.

Recommendation 3:	<p>https://standards.iso211.org/19157/-1/1/rec/optionalContent/additionalQualityMeasure</p> <p>Whenever possible, a <i>BasicMeasure</i> should be used as the basis for defining a new quality measure.</p> <p>NOTE A variety of measures are based on counting of erroneous items. There are also several measures dealing with the uncertainty of numerical values. In order to avoid repetition, the most common methods of constructing count-related measures, as well as general statistical measures, for one- and two-dimensional random variables are defined in terms of basic measures.</p>
-------------------	---

9.2.7 Definition

The definition is a representation of a concept by a descriptive statement which serves to differentiate it from related concepts (ISO 19104).

NOTE If the measure is derived from a basic measure, the definition is based on the basic measure definition and specialized for this measure.

9.2.8 Description

The measure description is the description of the measure including methods of calculation, with all formulae and/or illustrations needed to establish the result of applying the measure.

If the measure uses the concept of errors, it should be stated how an item is classified as incorrect. This is the case when the quality can only be reported as correct or incorrect.

Recommendation 4:	https://standards.iso211.org/19157/-1/1/rec/optionalContent/description If a measure uses the concept of errors for reporting correct or incorrect items, <i>description</i> should contain an explanation of when an item is classified as incorrect.
-------------------	---

9.2.9 Parameter

A measure parameter is an auxiliary variable used by the measure.

9.2.10 Value type

The value type is the data type used for reporting the result of the measure. The data types defined in ISO 19103 shall be used.

9.2.11 Value structure

A result may consist of multiple values. In such cases, the result shall be structured using the value structure as given in [C.3.3](#).

9.2.12 Source reference

The source reference is the citation of the documentation of the measure.

9.2.13 Example

The example is an example of applying the measure or the result obtained for the measure. More than one example may be provided.

9.3 User-defined data quality measures

Due to the nature of quality and geographic data, the list of standardized data quality measures cannot be complete. There can potentially be cases where the user of this document has to devise other data quality measures. When possible, these measures shall be defined using the data quality basic measures and the measure shall be defined using the structure given in [Clause 9](#). Additional examples of data quality measures can be found in ISO 19160-3:2020, Annex C.

Requirement 4:	https://standards.iso211.org/19157/-1/1/req/content/additionalQualityMeasure A new quality measure shall be defined as a specialization of <i>QualityMeasure</i> , or one of its subtypes (see Clause 9) according to the rules for metadata extensions (ISO 19115-1:2014, Annex C) and rules for domain profiles of standard schemas (ISO 19109:2015, 8.3). If the quality measure is derived from a basic measure, the basic measure shall be referenced. If an item is adopted from an external source, the reference to the external source shall be given. If a measure uses an auxiliary variable, a reference <i>MeasureParameter</i> shall be provided for the measure.
----------------	---

10 Data quality evaluation

10.1 The process for evaluating data quality

10.1.1 Introduction

Quality evaluation processes are used in different phases of a product life cycle, having different objectives in each phase. The phases of the life cycle considered here are specification, production, delivery, use and update.

The process for evaluating data quality is a sequence of steps to produce a data quality result.

10.1.2 The process flow

The quality evaluation process is a sequence of steps followed to produce a quality evaluation result. [Figure 11](#) illustrates a possible workflow for evaluating data quality; see also [Annex D](#) for a description of the concepts for evaluating and reporting data quality.

Recommendation 5:	https://standards.iso.org/19157-1/1/rec/content/qualityEvaluationProcess When evaluated geographic dataset is heterogeneous and quality is specified for its individual parts, separate evaluation should be carried out for individual parts of the dataset.
-------------------	---

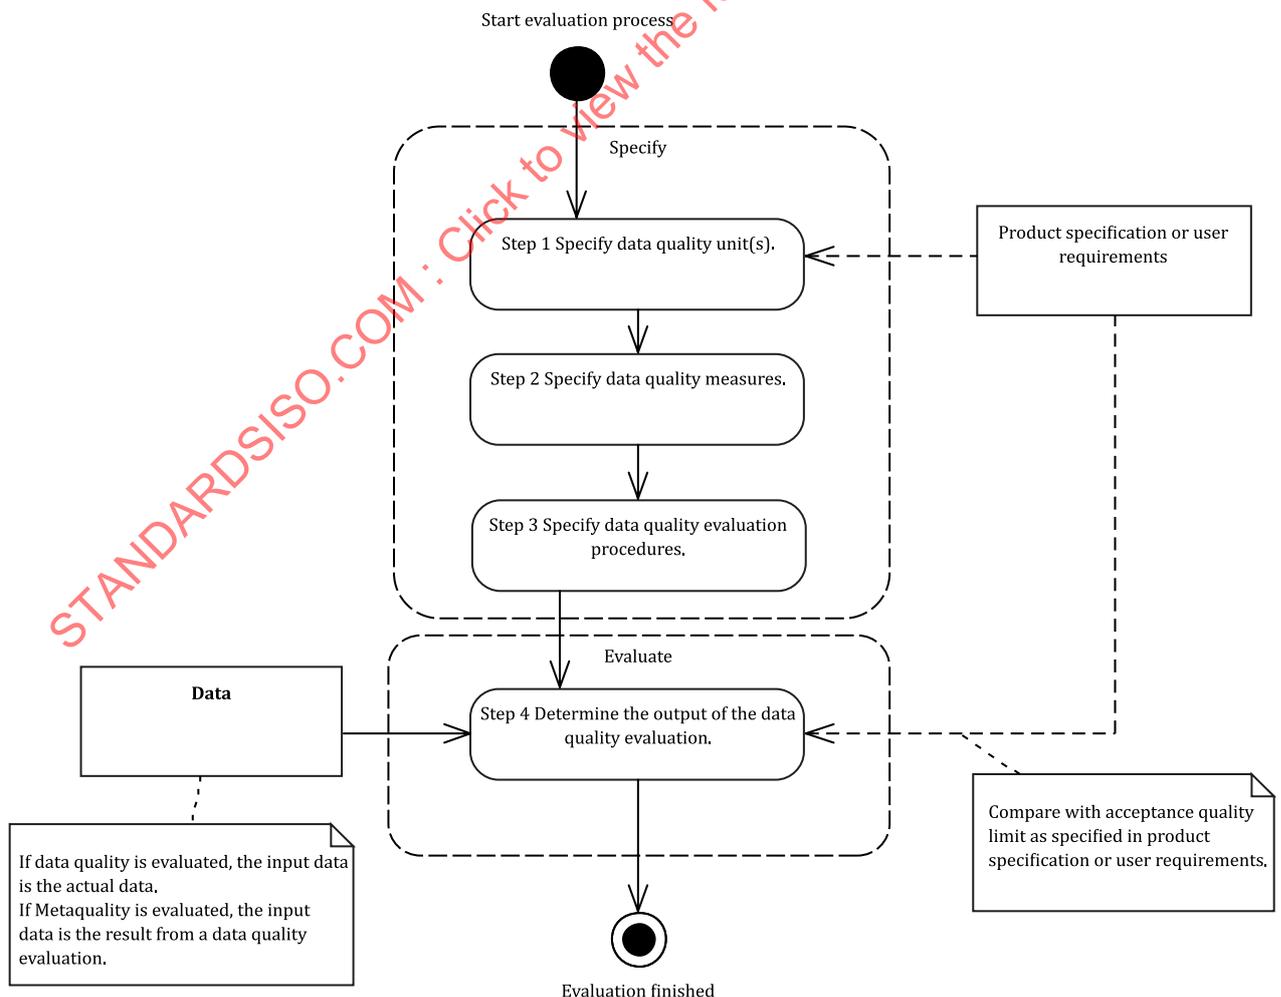

Figure 11 — Evaluating data quality

10.1.3 Process steps

Table 7 specifies the process steps involved in quality evaluation as illustrated in Figure 11.

Table 7 — Process steps

Process step	Action	Description
1	Specify data quality unit(s)	A data quality unit is composed of a scope and quality element(s); see 8.2. All data quality elements relevant to the data for which quality is to be described should be used. NOTE The data quality elements to be tested are described in 8.3 and Annex D provides guidelines for the use of quality elements. As described in 8.4, additional elements can be defined and used in quality evaluation.
2	Specify data quality measures	A measure should be specified for each data quality element. If no measure can be identified, a descriptive result may be provided.
3	Specify data quality evaluation procedures	A data quality evaluation procedure consists of applying one or more evaluation methods. Including: — standardized assessment method including conformance levels; — sampling strategy.
4	Determine the output of the data quality evaluation	A result is the output of applying the evaluation. A conformance to data product specification or user requirements is part of the quality evaluation output. The output is presented as metadata (e.g. in MD_Usage defined in ISO 19115-1) and a quality evaluation report.

Evaluation of metaquality may be performed after obtaining the output of the quality evaluation. The workflow described above is also a possible workflow for evaluating metaquality, with the following process steps: specify the metaquality element and the quality evaluation for which metaquality is evaluated, then specify a measure and an evaluation method and determine the output of the metaquality evaluation.

10.2 Data quality evaluation methods

10.2.1 Classification of data quality evaluation methods

A data quality evaluation procedure comprises one or more data quality evaluation methods. Data quality evaluation methods can be divided into two main classes: direct and indirect. Direct evaluation methods determine data quality through the comparison of the data with internal and/or external reference information. Indirect evaluation methods infer or estimate data quality using information on the data such as lineage.

Recommendation 6:	https://standards.iso/211.org/19157/-1/1/rec/optionalContent/evaluationMethodType
	Direct evaluation methods (<i>directInternal</i> or <i>directExternal</i>) should be used in preference to indirect evaluations.

The direct evaluation methods are further sub-classified by the source of the information needed to perform the evaluation, i.e. internal or external. Figure 12 shows the classes used for describing the evaluation methods.

NOTE Lineage is described in ISO 19115-1.

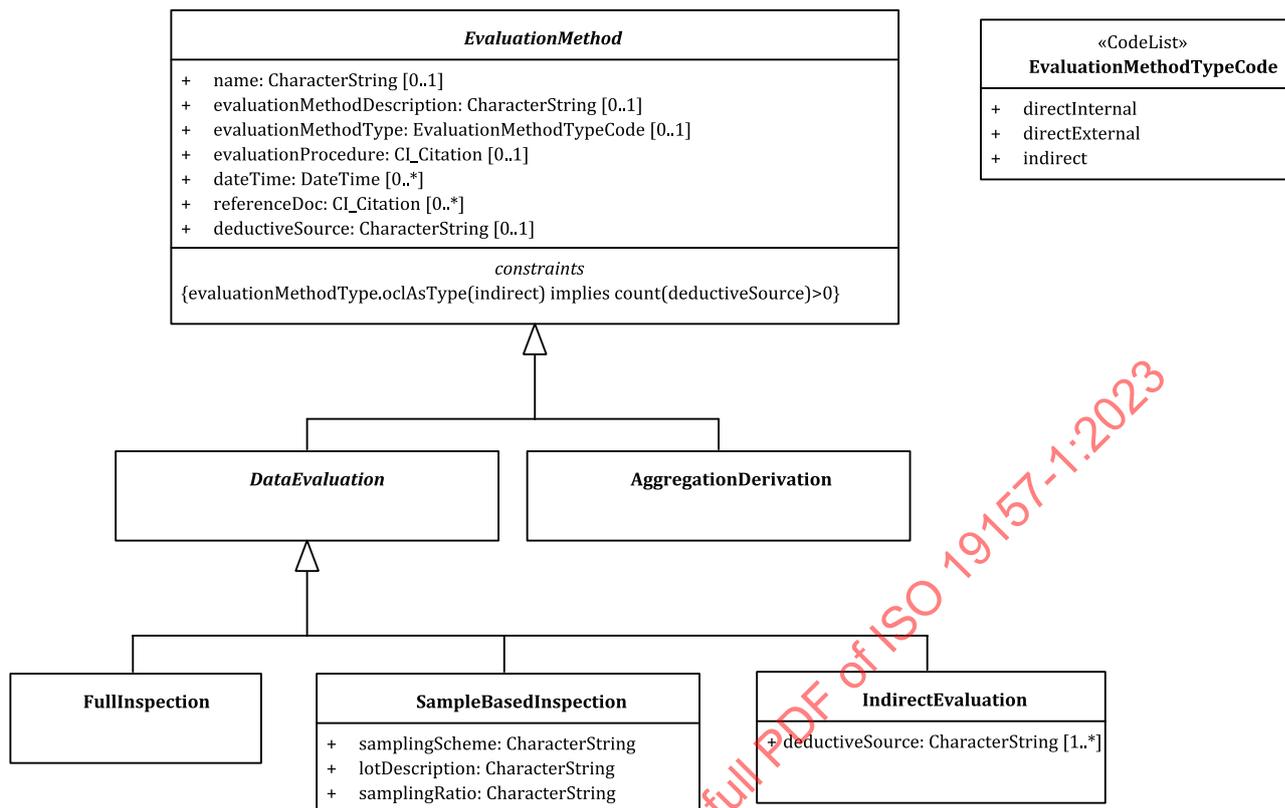

Figure 12 — Data quality evaluation methods

10.2.2 Direct evaluation

A direct evaluation method is a method of evaluating the quality of a dataset based on inspection of the items within the dataset.

The direct evaluation methods can be classified as internal or external. Internal direct data quality evaluation uses only data that resides in the dataset being evaluated. External direct quality evaluation requires reference data external to the dataset being tested.

NOTE 1 Reference data are data accepted as representing the universe of discourse.

For both external and internal direct evaluation methods, one of the following inspection methods may be used:

- full inspection: data quality evaluation tests every item specified by the data quality scope;
- sample-based inspection: data quality evaluation is performed on subsets of the geographic data defined by the data quality scope.

If the evaluation is based on a sample-based inspection the sample strategy should be explained in the quality evaluation report.

The full inspection is preferable. In case full inspection is not feasible, the sample-based inspection can be used. Annex E discusses sampling methods in detail.

10.2.3 Indirect evaluation

An indirect evaluation method is a method of evaluating the quality of a dataset based on external knowledge or experience of the data product and can be subjective.

This external knowledge may include information about dataset’s usage, lineage and purpose (see ISO 19115-1), or other data quality reports on the dataset or data used to produce the dataset. Data quality may be estimated, for example, from knowledge about the source, tools and methods used for the capturing of the data and evaluated against procedures and specifications worked out for this product. Indirectly evaluated data quality may also be based on experience alone or determined from the user feedback (for example, as reported in accordance with Reference [36]).

In some cases it can potentially be misleading or not even possible to report indirectly evaluated data quality as quantitative results. In such cases, the data quality may be described in textual form using a descriptive result; see 8.5.4.4.

10.3 Aggregation and derivation

Additional results may be produced by aggregating or deriving existing results without carrying out a new data quality evaluation.

Aggregation combines quality results from data quality evaluations based on different data quality elements or different data quality scopes.

Additional results may also be derived from existing results, for example, when a conformance result is obtained by comparing a quantitative result to a conformance level. This is useful if the result is expressed differently from the conformance level, for example.

NOTE 1 Aggregation can be used to aggregate results of different data quality elements to describe the conformance to a data product specification.

NOTE 2 Aggregation is further described in Annex G. Subclause 11.2.1 and Annex D describe how to report aggregation.

NOTE 3 Subclause 11.2.2 and Annex D describe how to report derivation.

EXAMPLE If the result is expressed with a significance level of 95 % and the conformance level is expressed with a significance level of 99 %, the result could be recalculated to be of the same significance level as the conformance level.

11 Data quality reporting

11.1 General

Data quality shall be reported as metadata and may be complemented with a quality evaluation report.

Requirement 5:	https://standards.iso211.org/19157/-1/1/req/content/dataQualityMetadata Data quality shall be reported as metadata in accordance with Clause 8, Clause 11 and Annex C of this document, and in accordance with ISO 19115-1.
----------------	--

In order to provide more details than reported as metadata, and including details of the data quality evaluation, such as the specific process steps executed in the evaluation, a quality evaluation report may additionally be created. The metadata description includes a reference to the quality evaluation report when it exists (see Figure 13).

Requirement 6:	https://standards.iso211.org/19157/-1/1/req/content/qualityEvaluationReport An optional quality evaluation report shall not replace the metadata.
----------------	--

Recommendation 7:	https://standards.iso211.org/19157/-1/1/rec/optionalContent/reportReference If a quality evaluation report exists for the reported data quality metadata, a reference to this report should be provided.
-------------------	---

NOTE 1 See also [B.4.3.2](#) for more information on how to report data quality and the complementary role between metadata and quality evaluation report.

NOTE 2 See [E.4](#) for examples of how to report data quality.

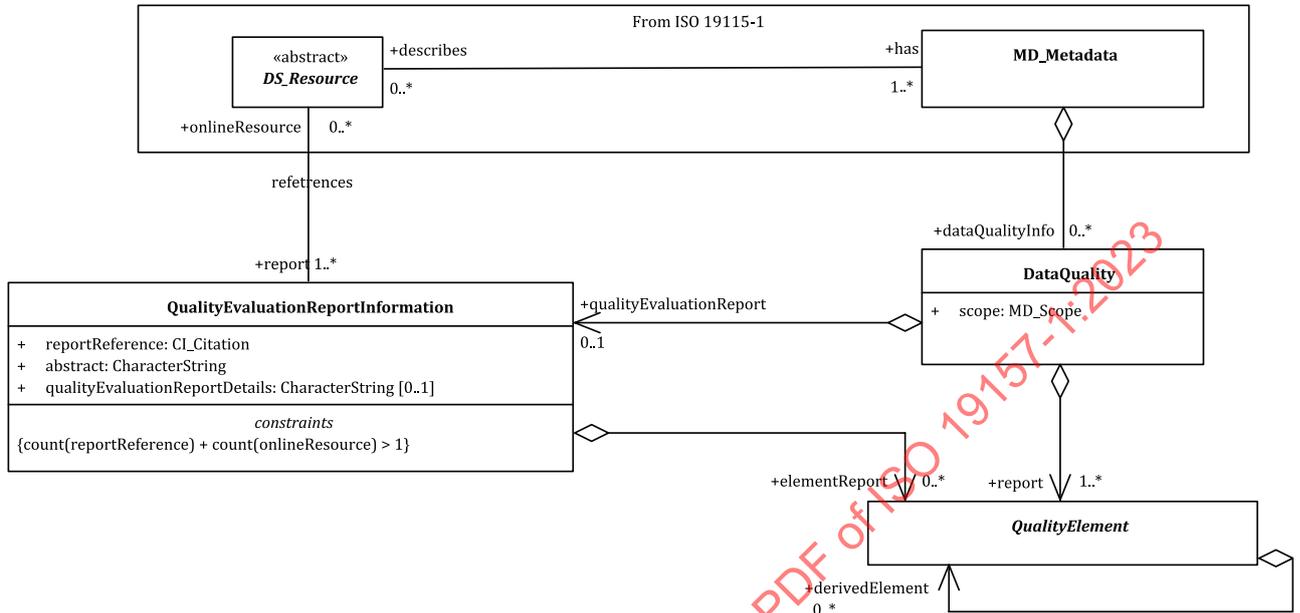

Figure 13 — Reporting data quality

11.2 Particular cases

11.2.1 Reporting aggregation (aggregated results)

A quality evaluation report may include information about aggregated results.

Recommendation 8:	https://standards.isotc211.org/19157/-1/1/rec/optionalContent/aggregatedResult Where the result has been aggregated, a quality evaluation report should be provided to complete the information provided in the metadata. This report includes fully-detailed information on the original result [with measure(s) and evaluation procedure(s)], aggregated result and aggregation method.
-------------------	--

Recommendation 9:	https://standards.isotc211.org/19157/-1/1/rec/optionalContent/sameQualityElement When several quality results for the same data quality element are aggregated into a single result of this element, the result should be reported in metadata as a result for this data quality element. See D.4.1.2 and D.4.1.3 for examples.
-------------------	---

Recommendation 10:	https://standards.isotc211.org/19157/-1/1/rec/optionalContent/differentQualityElement When several quality results for different data quality elements are aggregated into a single result, this should be reported in metadata as a result of evaluation of a dataset's conformance with the data product specification or user requirements. See D.4.1.4 for an example.
--------------------	---

Requirement 7:	https://standards.iso/211.org/19157/-1/1/req/content/aggregatedResult
	When an aggregated result is reported in metadata, a reference to the original quality evaluation results on individual element(s) shall be provided.

11.2.2 Reporting derivation (derived results)

When derived results are only reported in metadata, a quality evaluation report should also be generated to provide the original data quality results from which the derived result has been determined. The metadata should then provide the reference to the quality evaluation report and the original data quality result.

Recommendation 11:	https://standards.iso/211.org/19157/-1/1/rec/optionalContent/qualityEvaluationReport
	A quality evaluation report detailing the source of derivation (e.g. quality results, derivation method) should be generated for a derived result.

Recommendation 12:	https://standards.iso/211.org/19157/-1/1/rec/optionalContent/derivedResultMetadata
	Metadata on a derived result should provide a reference to the quality evaluation report and the original data quality result.

A conformance result is often derived from a quantitative result. If only the conformance result is provided in metadata, then the quantitative results should be provided in a quality evaluation report.

11.2.3 Reference to the original data quality result

Permission 3:	https://standards.iso/211.org/19157/-1/1/per/permittedContent/sourceReference
	When derived or aggregated result(s) are reported in metadata, the reference to the original data quality result may be provided using two attributes: <ul style="list-style-type: none"> — the attribute <i>derivedElement</i> references a quality element [and its result(s)] described in the metadata; — the attribute <i>qualityEvaluationReportDetails</i> references the part of the quality evaluation report where the original result(s) are described.

11.2.4 Hierarchy principle

This document recognizes the principle of the hierarchical level.

Data quality specified at upper level (e.g. series) is applicable at lower level (e.g. dataset); see [Table 8](#).

Table 8 — Hierarchical levels

Upper level ↑	Series	
	Dataset	
	Subset	
↓ Lower level	Feature type	Attribute type
	Feature instance	Attribute instance

NOTE Quality for an instance of a feature, a feature attribute or associations between features can be reported as an attribute for that instance as defined in ISO 19109.

Recommendation 13:	https://standards.iso211.org/19157/-1/1/rec/optionalContent/hierarchy
	If the data quality differs between upper and lower level, then supplemental information should be provided at lower level.

12 Requirements for XML encoding

The exchange of data quality specification in XML format requires encoding rules. This clause specifies such rules and an XML schema. The requirements class for the XML encoding is documented in [Table 3](#).

Requirement 8:	https://standards.iso211.org/19157/-1/1/req/xml
	A data quality XML document shall be conformant with the XML schema https://schemas.iso211.org/19157/-1/dqc/1.0.0/dqc.xsd .

The XML schema follows the rules stated in ISO/TS 19139-1 for translation of UML models to XML schema.

The XML schema also uses the patterns for decoupling XML namespaces outlined in ISO/TS 19115-3:2016, Clause 8.

The XML schema definitions pertain to the following namespace: <https://schemas.iso211.org/19157/-1/dqc/1.0>. This namespace is abbreviated dqc.

This XML schema implements all the UML classes defined in this document and imports all relevant classes from other International Standards.

More details regarding the XML encoding can be found in [Annex H](#).

Annex A (normative)

Abstract test suite

A.1 Content of a data product specification

Conformance test	https://standards.iso211.org/19157/-1/1/conf/content/allContent
Reference	All normative statements in requirements class https://standards.iso211.org/19157/-1/1/req/content (see Table 4 in Clause 6).
Test purpose	Verify that the content of a data quality definition conforms to the UML model and additional requirements related to the elements in the UML model.
Test method	Identify the individual object and their attributes and associations to other objects. Verify that each such element is in conformance with multiplicity and data type as expressed in the UML model. For each individual object check for additional requirements beyond the semantics in the model. Verify that each such element meets specified criteria.
Test type	Basic.

A.2 XML encoding

Conformance test	https://standards.iso211.org/19157/-1/1/conf/xml/xmlEncoding
Reference	All normative statements in requirements class https://standards.iso211.org/19157/-1/1/req/xml (see Clause 12 and Annex H)
Test purpose	Verify the syntax of a data quality definition from the XML document.
Test method	Validate the XML document using the XML schema https://schemas.iso211.org/19157/-1/dqc/1.0.0/dqc.xsd .
Test type	Basic.

Annex B (informative)

Data quality concepts and their use

B.1 Framework of data quality concepts

A dataset may be produced for a specific application or for a set of presupposed applications. The quality of a dataset can only be assessed by knowledge about its data quality elements and, for some cases, indirectly by its non-quantitative quality information usage, lineage and purpose (see ISO 19115-1). The data quality elements evaluate the difference between the dataset and the universe of discourse (i.e. the perfect dataset that corresponds to the data product specification). The non-quantitative quality information provides general information from which quality-related knowledge may be derived.

Data quality concepts provide an important framework for data producers, as well as for data users. A data producer is given the means for validating how well a dataset reflects its universe of discourse as defined in the data product specification. Data users can assess the quality of a dataset to ascertain if it is able to satisfy the requirements of the data user's application (see [Figure B.1](#)).

It should be noted that quality results reported are valid against the data product specification or the user requirements used. Care should be taken when comparing quality results where the universe of discourse (i.e. the specification or user requirements) is different. If these are changed, then quality evaluation should be repeated against the changed specification or requirements.

EXAMPLE Typical examples of this are related to model transformation in Spatial Data Infrastructures or generalization. For example, if the geometry of a feature type is changed, then positional accuracy results are changed as well.

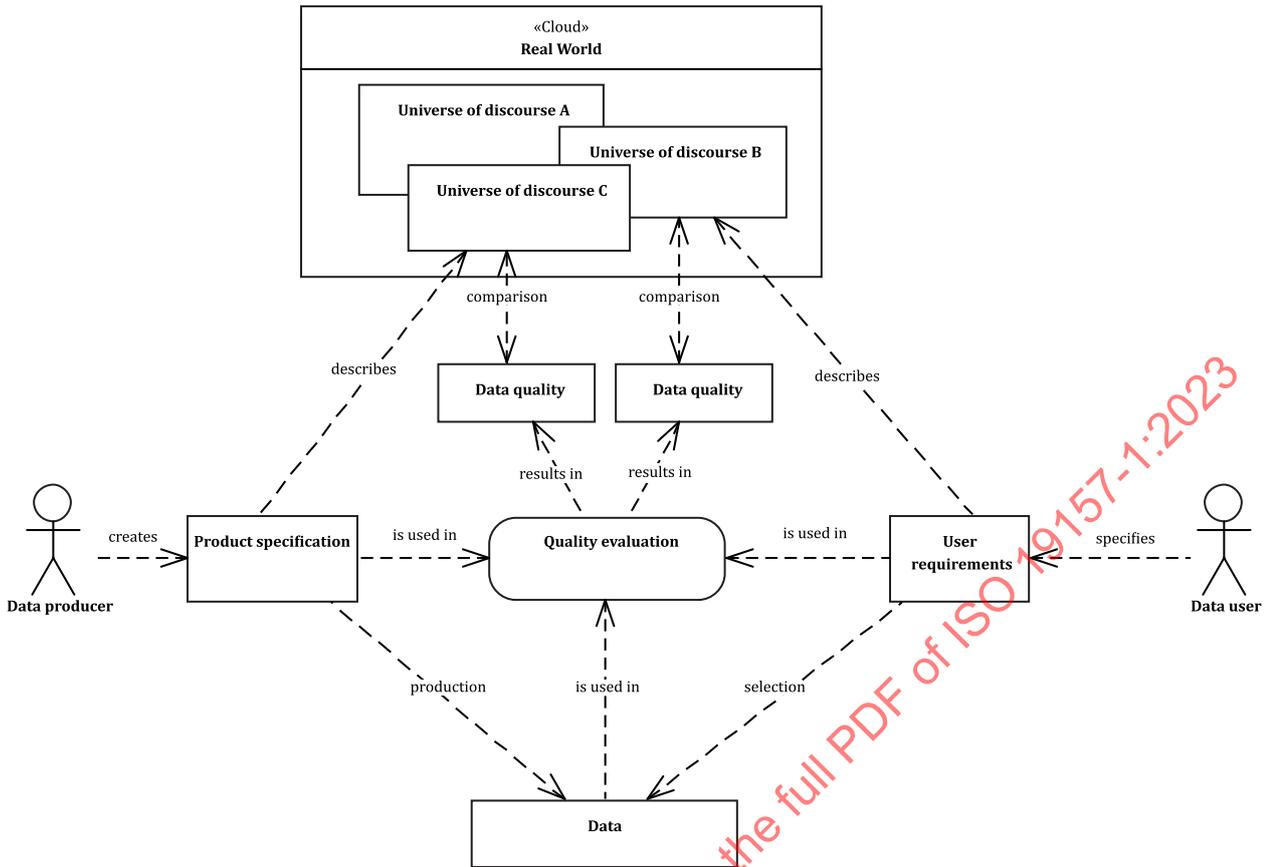

Figure B.1 — Framework of data quality concepts

B.2 The structure of datasets and components for quality description

A dataset may belong to a dataset series, meaning that all of the series' datasets are based on the same data product specification. The quality of all member datasets belonging to a dataset series may be the same.

A dataset can be viewed as containing a large but finite number of subsets of data. Subsets of data which share a commonality such as belonging to the same feature type, feature attribute or feature relationship or sharing a collection criteria or geographic or temporal extent do often have similar quality. A subset of data can be as small as a feature instance, attribute value or occurrence of a feature relationship and, theoretically, data quality concepts allow each feature instance, attribute value and occurrence of a feature relationship of a dataset to have its own quality. The quality of subsets of data within a dataset cannot be assumed to be the same as the quality of other parts of the dataset to which they belong. Data quality concepts allow for reporting the quality of a dataset and, additionally, for the differing quality of subsets of this dataset by identifying these groupings as the data specified by data quality scopes. The quality information reported for multiple data quality scopes smaller than the whole dataset for which quality is reported, provide a more complete and detailed picture of quality than the overall quality for the total dataset.

For a data producer, a data product specification describes a universe of discourse and contains the rules for constructing a dataset. For a data user, user requirements describe a universe of discourse, which may or may not match a dataset's universe of discourse. The quality of a dataset is how well it represents a universe of discourse. The quality of the same dataset can therefore differ depending on which universe of discourse it is evaluated against.

The quality of a dataset is described by data quality elements and their descriptors. Some quality-related information may also be provided by the non-quantitative elements usage, lineage and purpose. Metaquality provides quality information about quality evaluation.

Data quality elements allow for the evaluation of how well a dataset meets the criteria set forth in its data product specification or user requirements. Data quality elements can be evaluated in various ways and at different stages of a dataset's life cycle. Not all data quality elements are applicable to all types of datasets. Some data quality elements are applicable to larger datasets, while others are more suitable for subsets of data within a larger dataset. Some data quality elements are applicable for single instances of data as well as for larger numbers while some only are applicable for multiple instances.

This document identifies data quality elements primarily as a means of identifying and reporting separate categories of quality information. It additionally recognizes that data quality elements are frequently interrelated. For example, a coordinate error may generate at least two kinds of errors, a positional error and a topological error; see [Annex G](#). The meaning of the data quality elements in terms of the product and manner in which the data quality elements are handled are the responsibility of the quality evaluator.

All quality elements may be used to evaluate the conformance of the dataset against data product specification or a set of user-defined requirements. The evaluation may be based on a specific application or user requirements that cannot be described using the quality elements described above. In this case, components defined in other documents from the series (e.g. LI_Lineage from ISO 19115-1) can be used, or new elements can be defined according to the requirements for new quality elements defined in [8.4](#). Likewise, existing standard elements defined elsewhere may be referenced.

Data producers can demonstrate how a dataset is suitable for various identified usages. This can be done as free text in a dataset's identification (in the *abstract* of the MD_Identification class from ISO 19115-1) or, with MD_Usage class from ISO 19115-1, when a more detailed and structured explanation is needed.

Requirements for a dataset's fitness for use in the specific dataset's usage as defined by the producer can be provided in a data product specification by defining conformance quality levels for values of relevant quality elements.

EXAMPLE The property registers and the corresponding digital property map are suitable for property formation in the local reference system within urbanized areas.

Local positional accuracy real property boundary:	0,05 m
External positional accuracy real property boundary:	0,2 m
Omission joint property units:	< 1 %

B.3 When to use quality evaluation procedures

Quality evaluation procedures may be used in different phases of a product's life cycle. The stages of a product's life cycle during which quality evaluation may be applied are as follows.

- Development of a data product specification or user requirements: When developing a data product specification or defining user requirements, quality evaluation procedures may be used to facilitate the establishment of conformance quality levels that should be met by the final product. A data product specification or user requirements may include conformance quality levels for the data and quality evaluation procedures to be applied during production and updating.
- Quality control during dataset creation: At the production stage, the producer may apply quality evaluation procedures, either explicitly established or not contained in the data product specification, as part of the process of quality control. The description of the applied quality evaluation procedures, when used for production quality control, may be reported as lineage metadata including, but not necessarily limited to, the quality evaluation procedures applied, conformance quality levels established and the results.

- Inspection for conformance to a data product specification: On completion of the production, a quality evaluation process may be used to produce and report data quality results. These results may be used to determine whether a dataset conforms to its data product specification or not. If the dataset passes inspection (composed of a set of quality evaluation procedures), the dataset is considered to be ready for use. The results of the inspection operation should be reported in accordance with [Clause 11](#). See also the example in [Annex D](#) describing the evaluation and reporting of data quality. The outcome of the inspection will be either acceptance or rejection of the dataset. If the dataset is rejected, then, after the data has been corrected, a new inspection will be required before the product can be deemed to be in conformance with the data product specification.
- Evaluation of dataset conformance to user requirements: Quality evaluation procedures may be used to establish if a dataset meets the conformance quality levels specified in user requirements. Indirect as well as direct methods may be used in analyses of dataset conformance to user requirements.
- Quality control during dataset update: Quality evaluation procedures are applied to dataset update operations, both to the items being used for updates and to benchmark the quality of the dataset after an update has occurred.

B.4 Reporting quality information

B.4.1 Why report data quality

The need to report data quality exists for a number of reasons including the following:

- to aid discovery and encourage use of the dataset;
- to demonstrate the compliance to a data product specification or to user requirements;
- as part of supplier management initiatives;
- to permit downstream judgements about the quality of information derived from the dataset;
- to permit rational (optimal) decision-making when it is known that all data contains imperfections.

B.4.2 When to report quality information

Datasets are continually being created, updated and merged with the result that the quality or a component of the quality of a dataset may change. The quality of a dataset can be affected by three conditions:

- when any quantity of data is deleted from, modified or added to a dataset,
- when a dataset's data product specification is modified or new user-specified data quality requirements are identified,
- when the real world has changed.

The first condition, a modification to a dataset, may occur frequently. Many datasets are not static. There is an increase in the interchange of information, the use of datasets for multiple purposes and an accompanying update and refinement of datasets to meet multiple purposes. If the reported quality of a dataset is likely to change with modifications of the dataset, the quality of this dataset should be reassessed and updated as required when changes occur.

Complete knowledge of all applicable data quality elements should be available when a dataset is created. Only the data producer's usage (assuming the data producer actually uses the dataset) of a dataset can initially be reported. There is a reliance on data users to report uses of a dataset that differ from its intended purpose so that continual updates to this particular data quality overview element can be made to reflect occurring, unforeseen uses.

The second condition, a modification to a dataset's data product specification, is most likely to occur before initial dataset construction and prior to the release of quality information. It is conceivable, however, that as a dataset is used, its data product specification is updated so that future modifications to the dataset will better meet the actual needs. As the data product specification changes, the quality of the current dataset also changes. The quality information for a dataset should always reflect the current dataset given its current data product specification.

The third condition, a change of the real world, occurs continuously. Changes can be caused by natural phenomena such as movements in the Earth's crust or erosion, but they are most often a result of human activity. Changes are often very rapid and dramatic. For this reason, the date of data collection is equally as important as the date of quality evaluation when judging the quality of a dataset. In some cases, when known, even the rate of change is of interest. The update frequency of the dataset can also be of interest in some cases. However, this document recognizes that it can potentially not be possible to create a new data quality report every time the real world changes.

B.4.3 How to report quality information with metadata and a quality evaluation report

B.4.3.1 General

Quality information may be reported as metadata and as a quality evaluation report. These two mechanisms complement each other by allowing the reporting of data quality evaluation with different levels of detail.

- The metadata aims at providing short, synthetic and generally-structured information to enable metadata interoperability and web services usage.
- The quality evaluation report may be used to provide fully-detailed information about the data quality evaluation. The quality evaluation report is to be referenced from the metadata as explained in [Clause 11](#).

For example, in the case of aggregation of different quality results, the quality evaluation report will provide full information on the original results (with evaluation procedures and measures applied), the aggregated result and the aggregation method, whereas the metadata can potentially describe only the aggregated result with a reference to the original results described in the quality evaluation report.

B.4.3.2 Reporting quality information as metadata

The class MD_Metadata, defined in ISO 19115-1, aggregates from zero to many data quality units (instances of the class DataQuality, as specified in this document); see [Figure B.2](#).

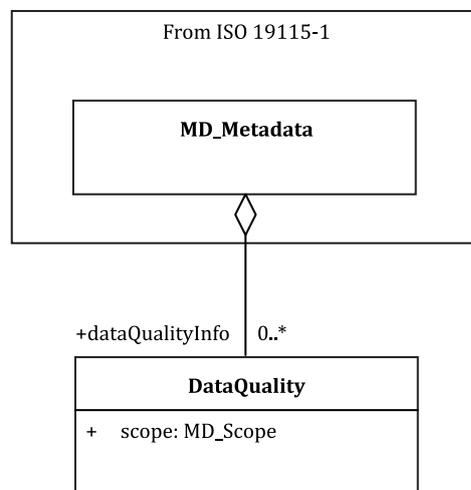

Figure B.2 — Data quality information

B.4.3.3 Reporting quality information within a quality evaluation report

The standardization of terminology (e.g. the data quality elements) and structure of the underlying data quality information will be of benefit to users familiar with the standard and facilitate better understanding and comparison. Furthermore, a statement of conformance to the standard within the report may be of value to users.

A quality evaluation report should contain a scope to easily identify the extent to which the report covers the dataset under evaluation.

Each report should contain sufficient information to meaningfully describe the relevant aspects of data quality and their results. This may take the form of references to supporting documentation such as a data product specification or measure register.

The full structure of this quality evaluation report has intentionally not been standardized so that each individual organization is able to adapt it for its own needs, practices and evaluation procedures. The report may be in free text. However, the amount of quality information may be important. It is therefore important to present the report in a succinct, easily understood and easily retrievable way. For example, a report may follow the structure described in this document. An example of a quality evaluation report is provided in [Annex D](#).

Annex C (normative)

Data dictionary for data quality

C.1 Data dictionary overview

C.1.1 Introduction

This data dictionary describes the characteristics of the data quality model defined in [Clauses 8, 9, 10](#) and [11](#). The dictionary is specified in tables with columns and rows in a hierarchy to establish relationships and an organization for the information.

The shaded table rows represent classes. The unshaded table rows represent class attributes and associations. The classes and class attributes within the data dictionary tables are defined by six table columns described in [C.1.2](#) to [C.1.7](#).

C.1.2 Name/role name

This is a label assigned to the class or class attribute. Class names start with an uppercase letter. Spaces do not appear in a class name. Instead, multiple words are concatenated, with each new sub-word starting with a capital letter (example: XnnnYmmm). Class names are unique within the entire data dictionary of this document. Class attribute names are unique within a class, not the entire data dictionary of this document. Class attribute names are made unique, within an application, by the combination of the class name and class attribute names. Role names are used to identify abstract model associations and are preceded by "Role name" to distinguish them from other class attributes. Names and role names may be in a language other than that used in this document.

C.1.3 Definition

This is the class or class attribute description.

C.1.4 Obligation/condition

C.1.4.1 General

This is a descriptor indicating whether a class or class attribute shall always be documented in the dataset or whether it is sometimes documented [i.e. contains value(s)]. This descriptor may have the following values: M (mandatory), C (conditional), or O (optional).

C.1.4.2 Mandatory (M)

This descriptor specifies that the class or class attribute shall be documented.

C.1.4.3 Conditional (C)

This descriptor specifies an electronically manageable condition under which at least one class, class attribute or association is mandatory. "Conditional" is used for one of the three following possibilities.

- Expressing a choice between two or more options. At least one option is mandatory and shall be documented.
- Documenting a class, class attribute or association if another class has been documented.

- Documenting a class attribute or association if a specific value for another class attribute has been documented. To facilitate reading by humans, the specific value is used in plain text. However, the code shall be used to verify the condition in an electronic user interface.

If the answer to the condition is positive, then the class, class attribute or association shall be mandatory.

C.1.4.4 Optional (0)

This descriptor specifies that the class, class attribute or association may or may not need to be documented. Optional classes or optional class attributes have been defined to provide a guide to those looking to fully document their data. (Use of this common set of defined elements will help promote interoperability among geographic data users and producers worldwide.) If an optional class is not used, the class attributes contained within that class (including mandatory attributes) will also not be used. Optional classes may have mandatory class attributes; those class attributes only become mandatory if the optional class is used.

C.1.5 Maximum occurrence

This descriptor specifies the maximum number of instances the class, class attribute or association may have. Single occurrences are shown by “1”; repeating occurrences are represented by “N”. Fixed number occurrences other than one are allowed, and will be represented by the corresponding number (i.e. “2”, “3”, etc).

C.1.6 Data type

This descriptor specifies a set of distinct values for representing the class attributes; for example, integer, real, string, DateTime, and Boolean. The data type column is also used to define classes, stereotypes and class associations.

NOTE Data types are defined in ISO 19103:2015, 6.5.2.

C.1.7 Domain

For a class (shaded rows), the domain indicates the line numbers covered by class attributes and associations for that class.

For a class attribute or association, the domain specifies the values allowed. The use of free text indicating unrestricted textual information used for the content of the field, or “unspecified domain” which may be any alphanumeric set of characters.

NOTE Domains are defined in ISO 19115-1:2014, B.1.7.

C.2 Data quality package data dictionary

C.2.1 Data quality

C.2.1.1 General

The global UML model for the whole data quality package is shown in [Figure 2](#).

[Table C.1](#) describes the properties of the UML model shown in [Figure 3](#) and [Figure 13](#).

Table C.1 — Data quality

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
1	DataQuality	Degree to which a set of inherent characteristics of data fulfils a requirement.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Aggregated Class (MD_Metadata)	Lines 2–4
2	Scope	The specific data to which the data quality information applies.	M	1	Class	MD_Scope <<DataType >> (ISO 19115-1)
3	Role name: report	A reference to the report (metadata or quality evaluation report) associated with the quality element.	M	N	Association	QualityElement (Abstract class) (C.2.1.2)
4	Role name: QualityEvaluationReport	A reference to the report (metadata or quality evaluation report) associated with the quality element.	O	1	Association	QualityEvaluationReport-Information (C.2.1.6)

C.2.1.2 Data quality element

Table C.2 describes the UML model shown in [Figure 2](#), [Figure 4](#), [Figure 5](#), [Figure 10](#) and [Figure 13](#).

Table C.2 — Data quality element

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
5	QualityElement	Aspect of quantitative quality information.	Use obligation from referencing object.	Use maximum occurrence from referencing object	Aggregated Class (DataQuality) (Abstract class)	Lines 6–9
6	Role name: evaluation-Method	Evaluation information.	M	N	Association	EvaluationMethod (C.2.1.4)
7	Role name: result	Value (or set of values) obtained from applying a data quality measure or the outcome of evaluating the obtained value (or set of values) against a specified acceptable conformance quality level.	M	N	Association	QualityResult (Abstract class) (C.2.1.5)

Table C.2 (continued)

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
8	Role name: derivedElement	In case of aggregation or derivation, indicates the original element.	0	N	Association	QualityElement (Abstract class) (C.2.1.2)
9	Completeness	Presence and absence of features, their attributes and their relationships.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (QualityElement) (Abstract class)	Lines 6–9
10	Commission	Excess data present in the dataset, as described by the scope.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (Completeness)	Lines 6–9
11	Omission	Data absent from the dataset, as described by the scope.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (Completeness)	Lines 6–9
12	LogicalConsistency	Degree of adherence to logical rules of data structure, attribution and relationships (data structure can be conceptual, logical or physical).	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (QualityElement) (Abstract class)	Lines 6–9
13	Conceptual-Consistency	Adherence to rules of the conceptual schema.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (Logical Consistency)	Lines 6–9
14	DomainConsistency	Adherence of values to the value domains.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (Logical Consistency)	Lines 6–9
15	FormatConsistency	Degree to which data are stored in accordance with the physical structure of the dataset, as described by the scope.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (Logical Consistency)	Lines 6–9
16	Topological-Consistency	Correctness of the explicitly encoded topological characteristics of the dataset as described by the scope.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (Logical Consistency)	Lines 6–9

Table C.2 (continued)

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
17	<i>PositionalAccuracy</i>	Accuracy of the position of features.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (QualityElement) (Abstract class)	Lines 6–9
18	AbsolutePositionalAccuracy	Closeness of reported coordinate values to values accepted as true in a standard coordinate reference system.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (PositionalAccuracy)	Lines 6–9
19	RelativePositionalAccuracy	Closeness of the relative positions of features in the scope to their respective relative positions accepted as true in a local coordinate reference system.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (PositionalAccuracy)	Lines 6–9
20	GriddedDataPositionalAccuracy	Closeness of gridded data position values to values accepted as true.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (PositionalAccuracy)	Lines 6–9
21	<i>ThematicQuality</i>	Accuracy of quantitative attributes and the correctness of non-quantitative attributes and of the classifications of features and their relationships.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (QualityElement) (Abstract class)	Lines 6–9
22	ThematicClassificationCorrectness	Comparison of the classes assigned to features or their attributes to a universe of discourse.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (ThematicQuality)	Lines 6–9
23	NonQuantitativeAttributeCorrectness	Measure of whether a non-quantitative attribute is correct or incorrect	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (ThematicQuality)	Lines 6–9
24	QuantitativeAttributeAccuracy	Closeness of the value of a quantitative attribute to a value accepted as or known to be true.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (ThematicAccuracy)	Lines 6–9

Table C.2 (continued)

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
25	<i>TemporalQuality</i>	Accuracy of the temporal attributes and temporal relationships of features.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (QualityElement) (Abstract class)	Lines 6–9
26	AccuracyOfA-TimeMeasurement	Closeness of reported time measurements to values accepted as true.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (TemporalQuality)	Lines 6–9
27	TemporalValidity	Validity of data with respect to time.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (TemporalQuality)	Lines 6–9
28	<i>Metaquality</i>	Information about the reliability of data quality results.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (QualityElement) (Abstract class)	Lines 30 and 6–9
29	<i>Role name: relatedQualityElement</i>	The quality element where the metaquality information applies.	M	1	Association	QualityElement (Abstract class) (C.2.1.2)
30	Confidence	Trustworthiness of a data quality result.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (Metaquality)	Lines 30 and 6–9
31	Representativity	Degree to which the sample used has produced a result which is representative of the data within the data quality scope.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (Metaquality)	Lines 30 and 6–9
32	Homogeneity	Expected or tested uniformity of the results obtained for a data quality evaluation.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (Metaquality)	Lines 30 and 6–9

C.2.1.3 Measure reference

Table C.3 describes the UML model shown in Figure 6.

Table C.3 — Measure reference

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
33	MeasureReference	Reference to the measure used.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Aggregated Class (Element)	Lines 35–37
34	measureIdentification	Identifier of the measure, value uniquely identifying the measure within a namespace.	0	1	Class	MD_Identifier << DataType >> (see ISO 19115-1:2014, Table B.17.2)
35	nameOfMeasure	Name of the test applied to the data.	C/if measureIdentification not documented.	N	Character string	Free text
36	measureDescription	Description of the measure.	C/if measureIdentification not documented.	1	Character string	Free text

C.2.1.4 Data quality evaluation

Table C.4 describes the UML model shown in [Figure 7](#), [Figure 11](#) and [Figure 12](#).

Table C.4 — Data quality evaluation

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
37	<i>Evaluation-Method</i>	Description of the evaluation method and procedure applied.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Aggregated Class (QualityElement)	Lines 39–45
38	name	Name of the evaluation method.	0	1	Character-String	Free text
39	evaluation-MethodDescription	Description of the evaluation method.	0	1	Character-String	Free text
40	evaluation-MethodType	Type of method used to evaluate quality of the data.	0	1	Class	EvaluationMethodType Code << CodeList >> (C.3.2)
41	evaluationProcedure	Reference to the procedure information.	0	1	Class	CI_Citation << DataType >> (see ISO 19115-1:2014, Table B.16)
42	dateTime	Date or range of dates on which a data quality measure was applied.	0	N	Class	DateTime (see ISO 19103:2015)

Table C.4 (continued)

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
43	referenceDoc	Information on documents which are referenced in developing and applying a data quality evaluation method.	0	N	Class	CI_Citation << DataType >> (see ISO 19115-1:2014, Table B.16)
44	deductive-Source	Information on which data are used as sources in deductive evaluation method.	0	1	Character-String	Free text
45	DataEvaluation	Data evaluation method.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (Evaluation-Method) (Abstract class)	Lines 39–45
46	FullInspection	Data quality evaluation tests every item specified by the data quality scope.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (DataEvaluation)	Lines 39–45
47	SampleBasedInspection	Data quality evaluation is performed on subsets of the geographic data defined by the data quality scope.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (DataEvaluation)	Lines 39–45 and 49–51
48	samplingScheme	Information on the type of sampling scheme and description of the sampling procedure.	M	1	Character-String	Free text
49	lotDescription	Information on how lots are defined.	M	1	Character-String	Free text
50	samplingRatio	Information on how many samples on average are extracted for inspection from each lot of population.	M	1	Character-String	Free text
51	IndirectEvaluation	Data quality evaluation based on external knowledge of experience of the data product.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (DataEvaluation)	Lines: 39–45

Table C.4 (continued)

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
52	Aggregation-Derivation	Aggregation or derivation method.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (Evaluation-Method)	Lines 39–45

C.2.1.5 Data quality result

Table C.5 describes the UML model shown in Figure 8.

Table C.5 — Data quality result

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
53	<i>QualityResult</i>	Generalization of more specific result classes.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Aggregated Class (Element) (Abstract class)	Lines 55-56
54	resultScope	Scope of the result.	0	1	Class	MD_Scope (ISO 19115-1:2014)
55	dateTime	Date when the result was generated.	0	1	Class	DateTime (see ISO 19103:2015)
56	QuantitativeResult	The values or information about the value(s) (or set of values) obtained from applying a data quality measure	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (Result)	Lines 58-60 and 55-56
57	value	Quantitative value or values, content determined by the evaluation procedure used, accordingly with the value type and valueStructure defined for the measure.	M	N	Class	Record (see ISO 19103:2015)
58	valueUnit	Value unit for reporting a data quality result.	C/If value is described with a number.	1	Class	UnitOfMeasure (see ISO 19103:2015)
59	valueRecord-Type	Value type for reporting a data quality result, depends on the implementation.	0	1	Class	RecordType << Metaclass >> (see ISO 19103:2015)

Table C.5 (continued)

60	ConformanceResult	Information about the outcome of evaluating the obtained value (or set of values) against a specified acceptable conformance quality level.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (QualityResult)	Lines 62-64 and 55-56
61	specification	Citation of data product specification or user requirement against which data are being evaluated.	M	1	Class	CI_Citation << DataType >> (see ISO 19115-1:2014, Table B.16)
62	explanation	Explanation of the meaning of conformance for this result.	0	1	CharacterString	Free text
63	pass	Indication of the conformance result where 0 = fail and 1 = pass.	M	1	Boolean	1 = yes 0 = no
64	DescriptiveResult	Data quality descriptive result.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified Class (Result)	Lines 66 and 55-56
65	statement	Textual expression of the descriptive result.	M	1	CharacterString	Free text
66	CoverageResult	Result of a data quality measure organizing the measured values as a coverage.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Specified class (Result)	Lines 68-71 and 55-56
67	spatialRepresentationType	Method used to spatially represent the coverage result.	M	1	Class	MD_SpatialRepresentationTypeCode <<CodeList>> (ISO 19115-1:2014/Amd 1:2018)
68	<i>Role name:</i> resultSpatialRepresentation	Provides the digital representation of data quality measures composing the coverage result.	M	1	Association	MD_SpatialRepresentation <<Abstract>> (ISO 19115-1:2014/Amd 1:2018)

Table C.5 (continued)

69	Role name: resultContent	Provides the description of the content of the result coverage when the quality coverage is included with the resource being described, i.e. semantic definition of the data quality measures.	C/if result-Format not provided.	N	Association	MD_RangeDimension (ISO 19115-1:2014)
70	Role name: resultFormat	Provides information about the format of the result coverage data.	C/if result-Content not provided.	1	Association	MD_Format (ISO 19115-1:2014)

C.2.1.6 Quality evaluation report information

Table C.6 describes the UML model shown in Figure 13.

Table C.6 — Quality evaluation report information

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
71	QualityEvaluationReportInformation	Reference to an external quality evaluation report.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Class	Lines 73-77
72	reportReference	Reference to the associated quality evaluation report.	C/if onlineResource not provided.	1	Class	CI_Citation << DataType >> (see ISO 19115-1:2014, Table B.16)
73	abstract	Abstract for the associated quality evaluation report.	M	1	Character-String	Free text
74	qualityEvaluationReportDetails	Reference to the original results in the quality evaluation report.	O	N	Character-String	Free text
75	Role name: elementReport	Data quality elements covered by the quality evaluation report.	O	N	Association	QualityElement
76	Role name: onlineResource	Reference to an online resource.	C/if reportReference not provided.	N	Association	DS_Resource <<Abstract>> (see ISO 19115-1:2014)

C.2.2 Data quality measure

C.2.2.1 General

The UML model for measures information is shown in Figure 10.

C.2.2.2 Data quality measures

Table C.7 describes the UML model shown in Figure 10.

Table C.7 — Data quality measures

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
77	QualityMeasure	Data quality measure.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Class	Lines 79-90
78	measureIdentifier	Value uniquely identifying the measure within a namespace.	M	1	Class	MD_Identifier << DataType >> (see ISO 19115-1:2014, Table B.17.2)
79	name	Name of the data quality measure applied to the data.	M	1	Character-String	Free text
80	alias	Another recognized name, an abbreviation or a short name for the same data quality measure.	O	N	Character-String	Free text
81	elementName	Name of the data quality element for which quality is reported.	M	N	Class	TypeName << interface >> (see ISO 19103:2015)
82	definition	Definition of the fundamental concept for the data quality measure.	M	1	Character-String	Free text
83	description	Description of the data quality measure, including all formulae and/or illustrations needed to establish the result of applying the measure.	M	N	Class	MeasureDescription << Datatype >> (C.2.2.5)
84	valueType	Value type for reporting a data quality result (shall be one of the data types defined in ISO 19103:2015).	M	1	Class	TypeName << interface >> (see ISO 19103:2015)
85	valueStructure	Structure for reporting a complex data quality result.	O	1	Class	ValueStructure << CodeList >> (C.3.3)
86	example	Illustration of the use of a data quality measure.	O	N	Class	MeasureDescription (C.2.2.5)

Table C.7 (continued)

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
87	Role name: basicMeasure	Name of the data quality basic measure from which the data quality measure is derived.	C/if derived from basic measure.	1	Association	BasicMeasure (C.2.2.3)
88	Role name: sourceReference	Reference to the source of an item that has been adopted from an external source.	C/if an external source exists.	N	Association	SourceReference (C.2.2.6)
89	Role name: parameter	Auxiliary variable used by the data quality measure, including its name, definition and optionally its description.	C/if required.	N	Association	MeasureParameter (C.2.2.4)

C.2.2.3 Data quality basic measure

Table C.8 describes the UML model shown in Figure 10.

Table C.8 — Data quality basic measure

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
90	BasicMeasure	Data quality basic measure.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Class	Lines 92-95
91	name	Name of the data quality basic measure applied to the data.	M	1	Character-String	Free text
92	definition	Definition of the data quality basic measure.	M	1	Character-String	Free text
93	example	Illustration of the use of a data quality measure.	O	1	Class	MeasureDescription << Datatype >> (C.2.2.5)
94	valueType	Value type for the result of the basic measure (shall be one of the data types defined in ISO 19103:2015).	M	1	Class	TypeName << interface >> (see ISO 19103:2015)

C.2.2.4 Data quality parameter

Table C.9 describes the UML model shown in Figure 10.

Table C.9 — Data quality parameter

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
95	MeasureParameter	Data quality parameter.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Class	Lines 97-101
96	name	Name of the data quality parameter.	M	1	Character-String	Free text
97	definition	Definition of the data quality parameter.	M	1	Character-String	Free text
98	description	Description of the data quality parameter.	0	1	Class	MeasureDescription << Datatype >> (C.2.2.5)
99	valueType	Value type of the data quality parameter (shall be one of the data types defined in ISO 19103:2015).	M	1	Class	TypeName << interface >> (see ISO 19103:2015)
100	valueStructure	Structure of the data quality parameter.	0	1	Class	ValueStructure << CodeList >> (C.3.3)

C.2.2.5 Data quality measure description

Table C.10 describes the UML model shown in Figure 10.

Table C.10 — Data quality measure descriptor

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
101	MeasureDescription	Data quality measure description.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Class	Lines 103-105
102	textDescription	Text description.	M	1	Character-String	Free text
103	extendedDescription	Illustration.	0	1	Class	MD_BrowseGraphic (see ISO 19115-1:2014, Table B.17.3)
104	formula	Description of formulas for the quality measure.	0	N	Class	FormulaType << Datatype >> (C.2.2.7)

C.2.2.6 Data quality measure source reference

Table C.11 describes the UML model shown in Figure 10.

Table C.11 — Data quality measure source reference

	Name / role name	Definition	Obligation / condition	Maximum occurrence	Data type	Domain
105	SourceReference	Reference to the source of the data quality measure.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Class	Line 107
106	citation	Reference to the source.	M	1	Class	CI_Citation << DataType >> (see ISO 19115-1:2014, Table B.16)

C.2.2.7 Data quality formula type

Table C.12 describes the UML model shown in [Figure 10](#)

Table C.12 — Data quality formula type

	Name/role name	Definition	Obligation/condition	Maximum occurrence	Data type	Domain
107	FormulaType	Description of the formula.	Use obligation from referencing object.	Use maximum occurrence from referencing object.	Class	Lines 109-112
108	key	Explanation of the formula.	M	1	Character-String	
109	language	The language used to express the formula.	M	1	Class	FormulaLanguage << CodeList >> (C.3.3)
110	languageVersion	The version of the language.	M	1	Character-String	
111	mathematical-Formula	The formula in the chosen language.	M	1	Character-String	

C.3 Code lists

C.3.1 Introduction

The stereotype classes << CodeList >> can be found below. These stereotype classes do not contain “obligation/condition”, “maximum occurrence”, “data type” and “domain” columns. As a << CodeList >> is extendable, none of these stereotype classes contain a value such as “other”.

C.3.2 Evaluation method type

Table C.13 describes the UML model shown in [Figure 12](#)

Table C.13 — Evaluation method type

	Name	Definition
1	EvaluationMethodTypeCode	Type of method for evaluating an identified data quality measure.

Table C.13 (continued)

	Name	Definition
2	directInternal	Method of evaluating the quality of a dataset based on inspection of items within the dataset, where all data required is internal to the dataset being evaluated.
3	directExternal	Method of evaluating the quality of a dataset based on inspection of items within the dataset, where reference data external to the dataset being evaluated is required.
4	indirect	Method of evaluating the quality of a dataset based on external knowledge.

C.3.3 Value structure

[Table C.14](#) describes the UML model shown in [Figure 10](#).

Table C.14 — Value structure

	Name	Definition
1	ValueStructure	Structure of the data quality parameter.
2	bag	Finite, unordered collection of related items (objects or values) that may contain duplicates (ISO 19103).
3	set	Unordered collection of related items (objects or values) with no repetition (ISO 19103).
4	sequence	Finite, ordered collection of related items (objects or values) that may be repeated (ISO 19103).
5	table	An arrangement of data in which each item may be identified by means of arguments or keys (ISO/IEC 2382),
6	matrix	Rectangular array of numbers (ISO/TS 19129).
7	coverage	Feature that acts as a function to return values from its range for any direct position within its domain (ISO/FDIS 19123-1).

C.3.4 Formula language

[Table C.15](#) describes the UML model shown in [Figure 10](#).

Table C.15 — Formula language

	Name	Definition
1	FormulaLanguage	The coding language of the formula.
2	MathJSON	A JSON-based format to represent math formulae (w3c.github.io).
3	MathML	XML-based language for describing mathematical notation (mozilla.org).
4	OpenMath	Extensible standard for representing the semantics of mathematical objects (openmath.org).

Annex D (informative)

Evaluating and reporting data quality

D.1 Introduction

This annex provides one main example describing the evaluation and reporting of data quality.

A few additional examples are provided in [E.5](#), pointing to the metadata reporting of specific cases like descriptive result, metaquality and sampling evaluation.

D.2 Dataset description

D.2.1 Data product specification

D.2.1.1 General

The data product specification defined in the following subclauses describes the universe of discourse. The specification defines those features, attributes and relationships that are considered important and should be present in the dataset.

NOTE This is not a complete example of a data product specification (see ISO 19131).

The product will comprise transport network (paths and roads), buildings (houses and industrial buildings) and trees.

D.2.1.2 Feature types

Each feature type, with zero or more attributes, is listed in [Table D.1](#). Each attribute name is followed by a value type (e.g. code list, data type, character string or integer) and by an optional value domain.

Table D.1 — Feature types

	Feature type	Attribute name	Value type	Value domain
Buildings	Industrial building			
	House	family name	CharacterString	
		number of occupants	Integer	
Transport network	Path			
	Road	condition	CodeList: Pavement	surfaced, unsurfaced
	Tree	height	CodeList: Tree-Height	A: from 1 m to 3 m; B: from 3 m to 5 m; C: from 5 m to 10 m; D: more than 10 m.

D.2.1.3 Rules

The feature types in [Table D.1](#) shall adhere to the following rules:

- trees with a height of less than 1 m shall not be recorded;

- the attribute “condition” of a road may have no value (“undetermined value”);
- the attributes “name” and “number of occupants” of a house may have no value (“undetermined value”).

D.2.1.4 Conformance quality levels

Overall data quality requirement: a dataset shall pass only if it conforms to quality requirements as listed below.

- a) Only feature types and attributes defined in this data product specification can be present in the dataset.

Transport network.

- b) Max. two items can be missing for each feature type.
- c) Max. two items can be in excess for each feature type.
- d) Max. two feature instances can be misclassified as another of the transport network feature type and zero as other feature types.

Buildings.

- e) Max. two items can be missing for each feature type.
- f) Max. two items can be in excess for each feature type.
- g) Max. two feature instances can be misclassified as another of the building feature types and zero as other feature types.

Trees:

- h) Max. 10 % missing trees.
- i) Max. 10 % trees in excess.
- j) Max. 20 % of the trees can have wrong height.
- k) No feature instances can be misclassified as other feature types.

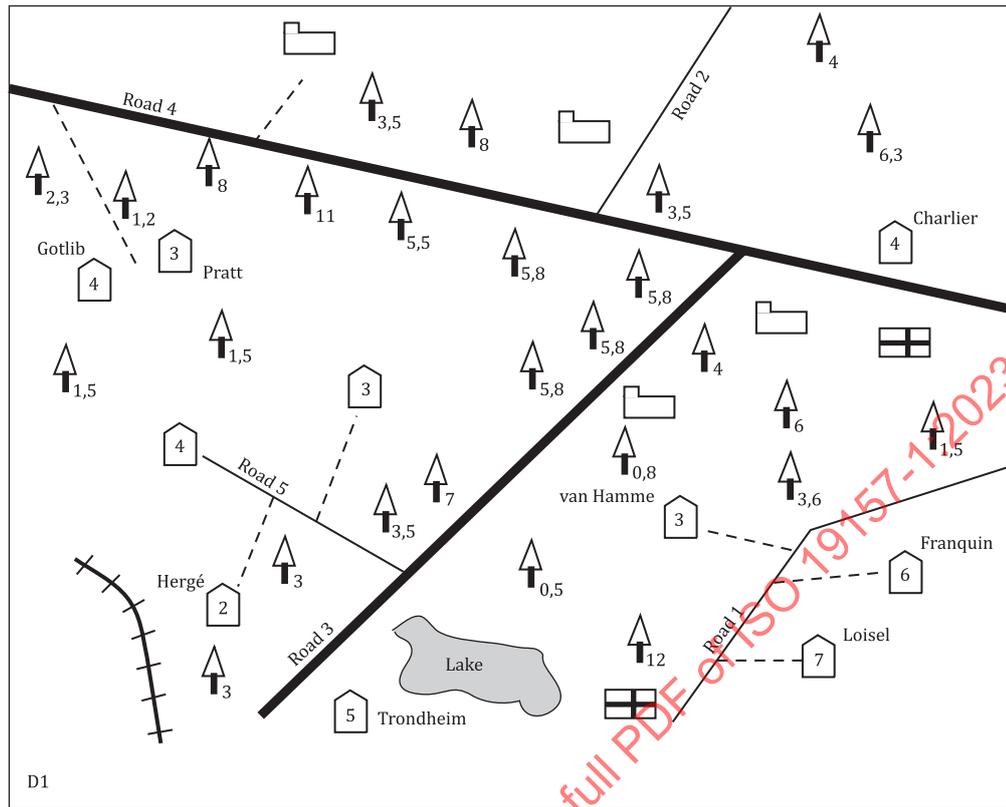

D.2.2 Representation of the real world, the universe of discourse and the dataset

The relationship between the three figures in this subclause is as follows:

- a) [Figure D.1](#) represents the “real world”, which generally contains more features than will be contained in the dataset;
- b) [Figure D.2](#) represents the “universe of discourse” given by the data product specification; it is that part of the real world that is to be included in the dataset, if the dataset is completely and accurately produced;
- c) [Figure D.3](#) represents the dataset as produced.

In all of the figures:

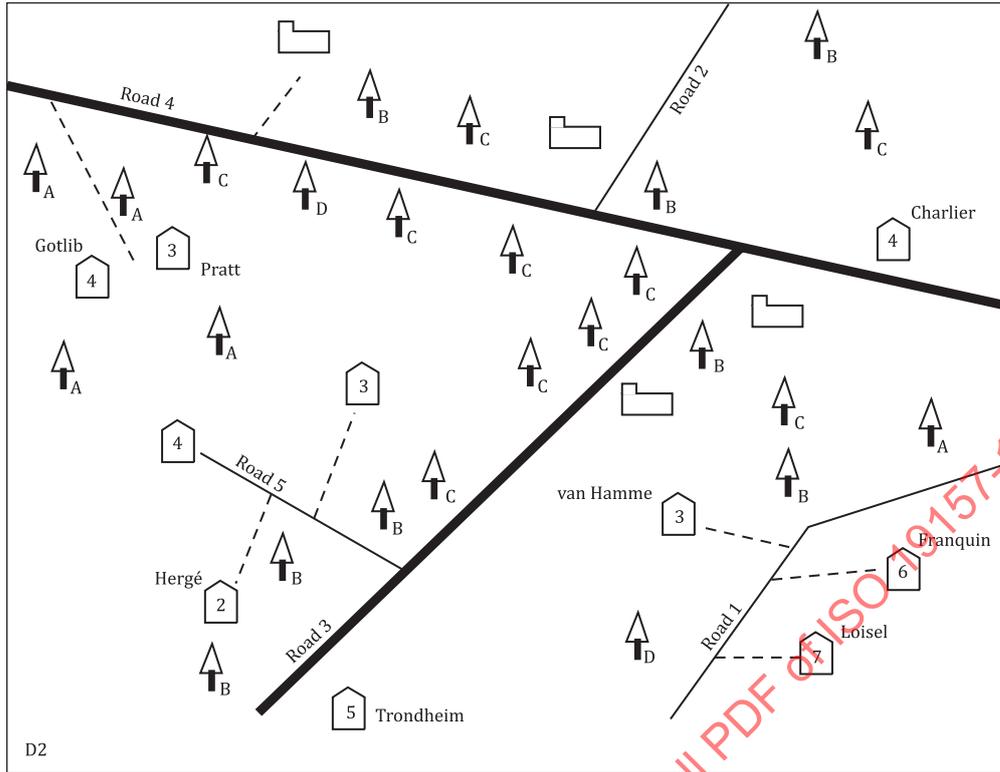

- the digit or letter representing the domain of digits under the symbol of a tree is the height of the tree in metres,
- the digit in the symbol of a house is the number of occupants of the house,
- the name of the occupants of a house is noted beside the symbol of the house.

Key

- | | | | |
|---|------------------------------|---|------------------------|
|  | hospital building |  | railway |
|  | industrial building |  | house with x occupants |
|  | tree with height of x metres |  | road: surfaced |
|  | path |  | road: unsurfaced |

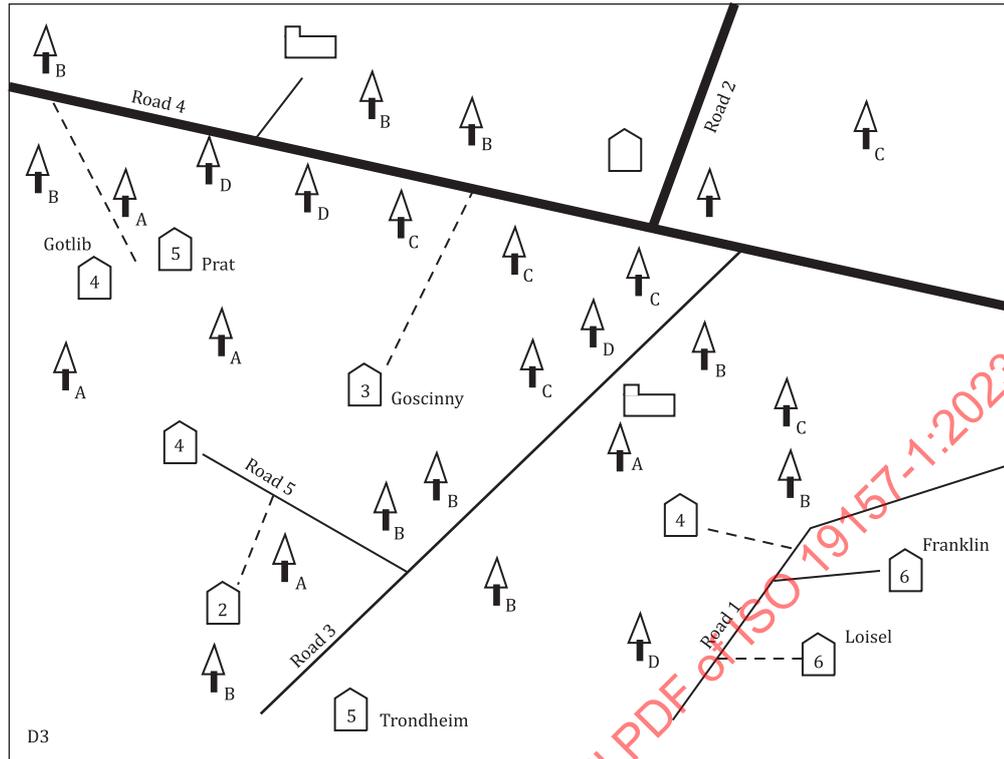

Figure D.1 — Graphical representation of the “real world”

Key

- | | | | |
|--|---------------------------------|---|------------------------|
|  | industrial building |  | house with x occupants |
|  | tree with height of 5 m to 10 m |  | road: surfaced |
|  | path |  | road: unsurfaced |

Figure D.2 — Graphical representation of the universe of discourse

**Key**

	industrial building		house with x occupants
	tree with height of 5 m to 10 m		road: surfaced
	path		road: unsurfaced

Figure D.3. — Graphical representation of the dataset

D.3 Quality evaluation process

D.3.1 Specify data quality unit(s)

A data quality unit is composed by a scope and quality element(s). In this example the completeness and thematic quality are evaluated to conform to the data product specification.

- The first quality unit is composed by conceptual consistency, completeness (commission and omission) and thematic classification correctness evaluated on the whole dataset.
- Two other quality units are composed by aggregated conceptual consistency, completeness (commission and omission) and thematic classification correctness evaluated on the transport networks and buildings.
- One quality unit is composed by quantitative attribute accuracy evaluated on feature type (tree).

Guidelines for choosing appropriate data quality elements are provided in [Annex F](#).

D.3.2 Specify data quality measures

For describing logical consistency, the following measure is used:

- Measure 9, “conceptual schema compliance”.

For describing completeness, the following measures are used:

- Measure 1, “excess item”;
- Measure 2, “number of excess items”;
- Measure 3, “rate of excess items”;
- Measure 5, “missing item”;
- Measure 6, “number of missing items”;
- Measure 7, “rate of missing items”.

For describing thematic quality, the following measure is used:

- Measure 62, “misclassification matrix”.

For describing overall conformance to the specification, the following measure is used:

- Measure 101, “data product specification passed”.

D.3.3 Specify data quality evaluation procedures

For this example, a direct external procedure is used.

Full inspection is used for this example.

NOTE An example of a sampling procedure is described in [D.5.5](#).

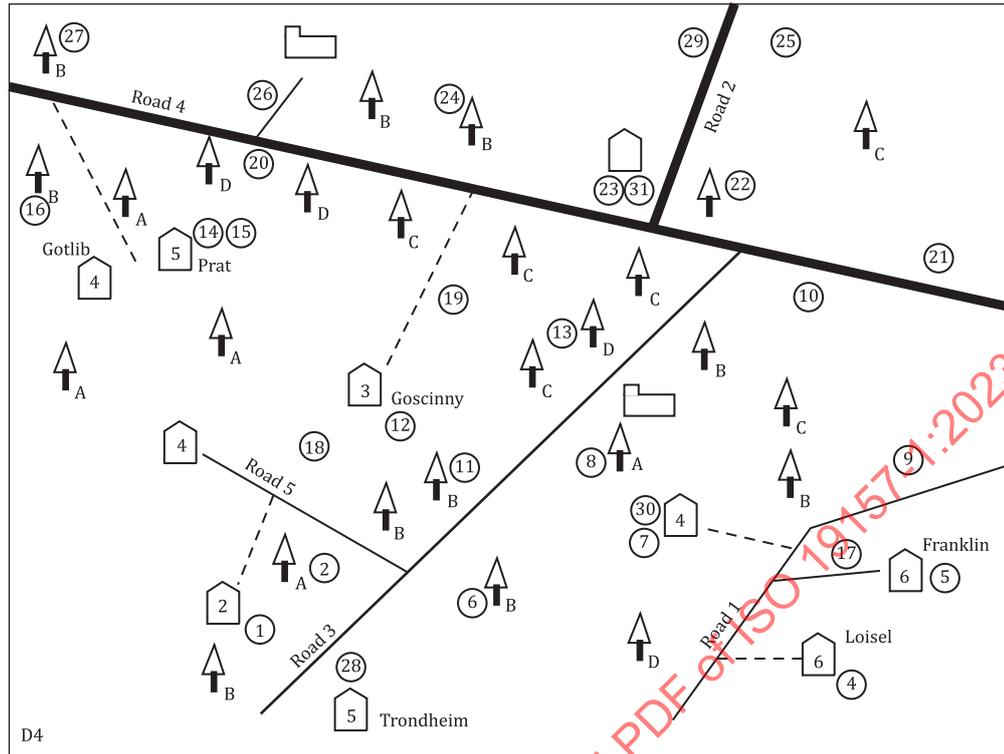

D.3.4 Specify conformance quality levels

The dataset is expected to be conformant to the data quality levels specified in [D.2.1.4](#).

D.3.5 Determine the output of the data quality evaluation (result)

D.3.5.1 Identification of errors

By comparing the dataset represented by [Figure D.3](#) with the universe of discourse represented by [Figure D.2](#), a list of errors in the example dataset can be produced, represented by [Figure D.4](#).

**Key**

	industrial building		error number
	tree with height of 3,5 m		house with x occupants
	path		road: surfaced
	road: unsurfaced		

Figure D.4 — Graphical representation of dataset error locations

The following is a list of detected errors with error numbers given for reference.

- Errors of omission and commission in recording of trees. Three trees (No. 6, No. 8, No. 27) are in excess and two trees are missing (No. 9, No. 25).
- Errors of omission and commission in recording paths. One path is missing (No. 18) and one is in excess (No. 19).
- A house replaces an industrial building (No. 23).
- Two paths are miscoded as roads (No. 17, No. 26).
- A house is missing (No. 21).
- Attribute error on roads. Two roads have the wrong “condition” (No. 29, No. 28).
- Two trees with a height less than 1 m are represented in the dataset (No. 6, No. 8) as excess items.
- Tree height attribute class code is missing. A tree is missing a class code while it is B in the universe of discourse (No. 22).
- Tree height attribute is misclassified. Six trees have the wrong height class assigned (No. 2, No. 11, No. 13, No. 16, No. 20, No. 24).

- House name attribute “family name” errors. The houses named “van Hamme” (No. 7) and “Hergé” (No. 1) in the universe of discourse have no name in the dataset. The house named “Gosciny” in the dataset (No. 12) has no name in the universe of discourse.
- House name attribute “family name” errors. The houses named “Franquin” (No. 5) and “Pratt” (No. 15) in the universe of discourse are named “Franklin” and “Prat” respectively in the dataset.
- House occupant count attribute errors. The occupant count attribute is missing for one house (No. 31) and wrong for three houses (No. 4, No. 14, No. 30).
- Omission error in industrial buildings. One industrial building is missing (No. 10).

NOTE The classification of errors as omission/commission, completeness or thematic quality is subjective. For example, the misclassification of a house as an industrial building could alternately be considered as an error of omission of the one and commission of the other.

D.3.5.2 Logical consistency

Only feature types and attributes defined in the data product specification are present in the dataset. See the conformance result for conceptual consistency in [Table D.2](#).

Table D.2 — Conformance result for logical consistency

Scope	Quality element	Conformance requirements	Number of evaluations	Counts yes/no	Pass
Dataset	Conceptual consistency	1) Only feature types and attributes defined in the application schema can be present in the dataset.	1 (no errors detected)	1/0	Yes

D.3.5.3 Completeness

D.3.5.3.1 General

Completeness in this example is classified by feature class. The types of measures tested for are commission and omission. The results are shown in [Tables D.3](#) to [D.5](#).

D.3.5.3.2 Quantitative result

[Table D.3](#) depicts a way to classify completeness using quantitative values.

Table D.3 — Completeness by feature class

Feature class	Number of instances in the universe of discourse	Commission count	Commission percentage ^a	Omission count	Omission percentage ^b
Path	7	1	14	1	43
Road ^c	5	2	40	0	0
Tree	25	1	12	2	8
Industrial building	4	0	0	1	50
House	10	0	10	1	10

^a Commission percentage = number of included items/number of items in the universe of discourse × 100.
^b Omission percentage = number of omitted items/number of items in the universe of discourse × 100.
^c If there is a small distinction between an unpaved road and a large path, the error 2 commission of roads could be a misclassification; see [D.3.5.4.2](#).

D.3.5.3.3 Derived conformance result

Table D.4 presents the conformance results derived from the quantitative results.

Table D.4 — Completeness conformance

Evaluation ID	Quality element	Measure and measure ID	Feature type	Conformance requirements	AQL ^a	Error count	Pop	Pass
1	Commission	Excess item (2)	Path	c	2	1	7	Yes
2	Omission	Missing item (5)	Path	b	2	3	7	No
3	Commission	Excess item (2)	Road	c	2	2	5	Yes
4	Omission	Missing item (5)	Road	b	2	0	5	Yes
5	Commission	Excess item (1)	Tree	i	10 %	3	25	No
6	Omission	Missing item (5)	Tree	h	10 %	2	25	Yes
7	Commission	Excess item (2)	Industrial building	f	2	0	4	Yes
8	Omission	Missing item (5)	Industrial building	e	2	2	4	Yes
9	Commission	Excess item (2)	House	f	2	1	10	Yes
10	Omission	Missing item (5)	House	e	2	1	10	Yes

^a AQL = acceptance quality limit

D.3.5.3.4 Aggregated conformance result

Conformance results regarding transport networks (paths and roads) and buildings (industrial and houses) are aggregated in Table D.5 using the following rule: if one of the original results is “No” the aggregated result will be “No”. (100 % pass fail; see Annex G)

Table D.5 — Aggregated completeness conformance

Scope	Quality element	Conformance requirements	Number of evaluations and ID (see Table D.4)	Counts yes/no	Pass
Transport network	Omission	b) Max. two missing for each feature type	2 (evaluation ID b and d)	1/1	No
Transport network	Commission	c) Max. two in excess for each feature type	2 (evaluation ID a and c)	2/0	Yes
Buildings	Omission	e) Max. two missing for each feature type	2 (evaluation ID h and j)	2/0	Yes
Buildings	Commission	f) Max. two in excess for each feature type	2 (evaluation ID g and i)	2/0	Yes

D.3.5.4 Thematic quality — classification correctness

D.3.5.4.1 General

Information about completeness can be further clarified by thematic quality information. For example, two of the three omitted paths are in fact classified as roads (see Table D.6). The results are shown in Tables D.6 to D.8.

D.3.5.4.2 Quantitative result

One way of depicting errors associated with thematic quality is by using the measure “misclassification matrix”.

Table D.6 is a misclassification matrix that shows errors by feature class. It explains how well the instances in the dataset are classified. The different percentages should always refer to the population in the dataset.

NOTE A misclassification matrix is a square matrix where the i, j element corresponds to the quantity classified as belonging to class j when it actually belongs to class i .

Table D.6 — Feature misclassification matrix

Universe of discourse	Dataset					
	Path	Road	Tree	Industrial building	House	Sum
Path	4	2	0	0	0	6
Road	0	5	0	0	0	5
Tree	0	0	23	0	0	23
Industrial building	0	0	0	2	1	3
House	0	0	0	0	9	9
Sum	4	7	23	2	10	46

The discrepancy between the sum and the number of items in the universe of discourse and the dataset comes from the missing and excess items.

D.3.5.4.3 Derived conformance result

Table D.7 presents the conformance results derived from the quantitative results.

Table D.7 — Thematic quality conformance

Evaluation ID	Quality element	Measure	Feature type	Conformance requirements	AQL	Mis-classification count	Pass
11	Thematic classification correctness	Number of incorrectly classified features	Path	d	2	2	Yes
12	Thematic classification correctness	Number of incorrectly classified features	Road	d	2	0	Yes
13	Thematic classification correctness	Number of incorrectly classified features	Industrial building	g	2	1	Yes
14	Thematic classification correctness	Number of incorrectly classified features	House	g	2	0	Yes
15	Thematic classification correctness	Number of incorrectly classified features	Tree	k	0	0	Yes

D.3.5.4.4 Aggregated conformance result

Conformance results regarding transport networks (paths and roads) and buildings (industrial and houses) are aggregated in Table D.8 using the following method: if one of the original results is “No” the aggregated result will be “No” (100 % pass fail; see Annex G).

Table D.8 — Aggregated classification correctness conformance

Scope	Quality element	Conformance requirements	Number of evaluations and ID (see Table D.7)	Counts yes/no	Pass
Transport network	Thematic classification correctness	d) Max. two feature instances in each feature type misclassified as another of the transport network feature type.	2 (evaluation No. 11 and 12)	2/0	Yes
Buildings	Thematic classification correctness	g) Max. two feature instances misclassified as another of the building feature types.	2 (evaluation No. 13 and 14)	2/0	Yes

D.3.5.5 Thematic quality – quantitative attribute accuracy

D.3.5.5.1 General

The type of measure tested for in this example is quantitative attribute accuracy. In Table D.9, only features that have a homologue in the same feature type (“class”) are taken into account. The results are shown in Table D.9 and Table D.10.

D.3.5.5.2 Quantitative result

Attribute height of trees is shown in Table D.9.

Table D.9 — Feature attribute height misclassification matrix — Tree height

Universe of discourse	Dataset				Sum
	Class A 1 m to 3 m	Class B 3 m to 5 m	Class C 5 m to 10 m	Class D > 10 m	
Class A	3	1	0	0	4
Class B	1	5	0	0	6
Class C	0	2	6	2	10
Class D	0	0	0	2	2
Sum	4	8	6	4	22

One tree is missing a class code and is therefore not counted in the misclassification matrix. This error could be reported as a domain consistency error.

D.3.5.5.3 Derived conformance result

Table D.10 presents the conformance results derived from the quantitative results.

Table D.10 — Thematic quality conformance

Quality element	Measure and measure ID	Feature type/attribute	Conformance requirements	AQL	Misclassification count	Pop	Pass
Quantitative attribute accuracy	Misclassification matrix (62)	Tree/height Class	j	20 %	6	22	No

D.3.5.6 Aggregated conformance to data product specification

In Table D.11, all the conformance results for buildings, transport network and trees are aggregated together with the conformance to the conceptual schema to provide the conformance to the data product specification following the registered measure “data product specification passed”.

Table D.11 — Conformance to the data product specification

Scope	Conformance requirements	Number of evaluations	Counts yes/no	Conformant
Dataset	To be conformant with the data quality requirements, a dataset shall pass all the data quality requirements in the application schema.	11 requirements	8/3 (Not passed req. 2, 9 and 10)	Dataset NOT conformant

D.4 Reporting data quality

D.4.1 Reporting as metadata

D.4.1.1 General

Subclauses [D.4.1.2](#) to [D.4.1.4](#) present examples of how to report the quality results as metadata, as described in this document ([Clause 11](#) and [Annex C](#)) and in ISO 19115-1. Indeed, one instance of MD_Metadata aggregates one or more instances of DataQuality.

In the examples, some instances of classes (DataQuality and QualityElement) have been given an identifier (ID) according to XML principles. These identifiers are used when referencing to those instances within other classes.

D.4.1.2 Reporting commission

[Table D.12](#) presents an example of how to report the quantitative results, derived conformance result and aggregated conformance result for the transport network feature types.

The mechanism for reporting these results is similar for the other feature types of the dataset.

Table D.12 — Reporting commission as metadata

XML element	Example	Comment
DataQuality		
scope: MD_Scope		
level: MD_ScopeCode	Dataset	Scope of this data quality unit
QualityEvaluationReport: QualityEvaluationReportInformation		
reportReference: CI_Citation		Reference and abstract of the attached quality evaluation report.
title: CharacterString	Reporting as quality evaluation report, see D.4.2 .

	dateType: CI_DateTypeCode	Creation	
	explanation: CharacterString	3 requirements out of 11 are not fulfilled: the dataset is not conformant.	
	pass: Boolean	False	

D.4.2 Reporting in a quality evaluation report

The structure of the quality evaluation report is free.

D.5 Additional examples

D.5.1 General

Some concepts have not been described in the previous example. The additional examples in [D.5.2](#) to [D.5.4](#) show how to report descriptive result, metaquality and sampling evaluation procedures.

Some concepts have not been described in the examples in [D.4](#).

D.5.2 Reporting descriptive results as metadata

Sometimes it can be impossible to express the evaluation of a data quality element in a quantitative way. Descriptive result could then be used. [Table D.15](#) is an example of the reporting as metadata of descriptive results.

Table D.15 — Reporting descriptive result as metadata

XML element		Example	Comment
	DataQuality		
	scope: MD_Scope		
	level: MD_ScopeCode	Dataset	The dataset describes archaeological objects.
	report: RelativeInternalPositionalAccuracy		
	evaluation: IndirectEvaluation		
	evaluationMethodType: EvaluationMethodTypeCode	Indirect	
	evaluationMethodDescription: CharacterString	Compares absolute positional accuracy of the archaeological objects and the absolute positional accuracy of the rivers.	

Table D.15 (continued)

XML element		Example	Comment
	deductiveSource: CharacterString	Positional accuracy of the rivers nearby the archaeological camp.	
	result: DescriptiveResult		
	statement: CharacterString	Relative positional accuracy between archaeological objects and rivers is higher than the absolute positional accuracy of the archaeological objects (5 m).	

D.5.3 Reporting metaquality as metadata

The absolute positional accuracy of the topological survey on an archaeological site is evaluated: the result is 5 m accuracy.

An evaluation of the quality of the evaluation is then provided using the confidence metaquality element, for which a measure called “Safety Factor” is used.

[Table D.16](#) describes how to report metaquality as metadata.

Table D.16 — Reporting metaquality as metadata

XML element		Example	Comment
DataQuality			
	scope: MD_Scope		
	level: MD_ScopeCode	Dataset	
	report: AbsolutExternalPositionalAccuracy <i>id = positionalaccuracy1</i>		Absolute positional accuracy report.
	measure: MeasureReference		An ID is provided to the data quality element in order to be able to reference it in the following metaquality element.
	nameOfMeasure: CharacterString	Root mean square error planimetry.	
	measureIdentification: MD_Identifier		
	code: CharacterString	47	
	measureDescription: CharacterString	Standard deviation where the true value is not estimated from the observations but known a priori.	All optional attributes have not been filled here.
	evaluation: FullInspection		
	evaluationMethodType: EvaluationMethodTypeCode	directExternal	
	evaluationProcedure: CI_Citation

value: Record	2.4	
valueUnit: UnitOfMeasure		

D.5.4 Reporting alternatives

D.5.4.1 Example of quality report using coverage result

The actuality of a dataset can be described by the latest control date. In this example a date is expressed as a year when an area was updated (e.g. from aerial photography, or for a theme updated from another dataset). [Figure D.5](#) illustrates the example of using a coverage result to report the evaluation of dataset's actuality. In the example in [Figure D.5](#) on the left, the updated part of the database is reported as a coverage, with pixel values representing the update year. The example in [Figure D.5](#) on the right shows a date when the data has been controlled with respect to completeness and positional accuracy for a scope (e.g. buildings and roads).

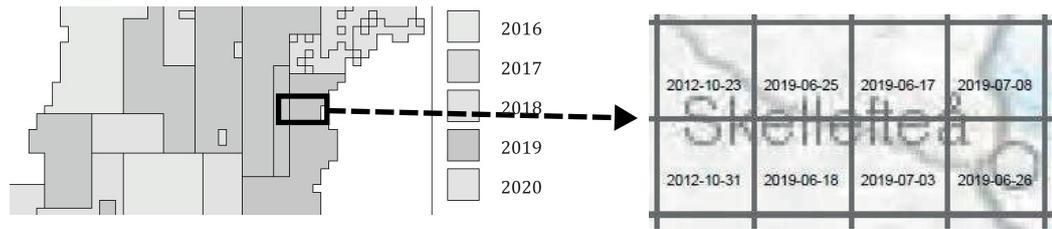

Figure D.5 — Coverage result to report evaluation of dataset's actuality

D.5.4.2 Example of quality report for lidar data height model using free text

General information about quality

The measured or estimated quality applies to the entirety of the surface scanned. For the area in question, it is therefore important to refer to metadata for information on survey technique, time of scanning and point density. Good knowledge of the local terrain conditions is also valuable in the interpretation of data.

Completeness

The point density on ground varies with terrain type, type of vegetation, the season in which laser scanning was performed and a number of other factors. This variation means that in some areas there are deficiencies in the point density, while in other places the point density is high.^[34]

D.5.4.3 Example of quality report for INSPIRE hydrography positional accuracy

Geometrical requirements on positional accuracy depend on the object's distinctness within a geographically limited area. Concrete objects have higher requirements than objects with diffuse boundaries.

Objects in the water have very high positional accuracy.

The shoreline is measured at normal water level, except in regulated lakes and rivers where it is measured at the maximum damming limit. The position of the shoreline may vary due to different water levels. Updating is only carried out when it is clear that there has been a major lasting change.

The positional accuracy of streams is high in open surfaces but is varied in forest areas where it is difficult to see through the canopy. Large errors regarding streams are gradually being corrected using laser/height data in forest areas. Other hydrographic objects have very high positional accuracy.^[35]

D.5.5 How to report sampling procedure

This example is based upon a topographic database produced by a European national land survey. The quality conformance levels have been defined in the data product specification.

Road feature type is evaluated in this example through a sampling evaluation.

The sampling procedure is applied using the principles of ISO 2859-1, as described in [Table D.17](#).

Table D.17 — Procedure for sampling

Process step	Example
Define a sampling method	Multistage sampling. Selecting enough sampling units so that sample ratio is fulfilled. Sampling is based on weighted features.
Define items	All features.
Divide the data quality scope (population) into lots	Number of datasets.
Divide lots into sampling units	N-number 1 km × 1 km squares.

Table D.17 (continued)

Process step	Example
Define the sampling ratio or the size of the sample	Sample size depends on the AQL value for that lot.
Select sampling units	Select required number of sampling units so that sampling ratio or sample size for items is fulfilled.
Inspect items in the sampling units	Inspect every item in the sampling units.

If the quality requirement for the feature is 1 nonconformity per 100 units (AQL = 1), then all features collected are checked from the data source. Inspection by sampling is done when the AQL = 4 or 15.

A lot used for testing should consist of datasets produced as far as possible at the same time and with the same methods. From the lot, sampling units of N -number 1 km × 1 km squares are selected so that the number of features in the sample is sufficient for an AQL = 4.

[Table D.18](#) is an example of how to report sampling procedure information as metadata.

Table D.18 — Reporting results of sampling evaluation as metadata

XML element	Example
DataQuality	
scope: MD_Scope	
level: MD_ScopeCode	Feature Type.
levelDescription: MD_ScopeDescription	
features: GF_FeatureType	Road.
report: Commission	
measure: MeasureReference	
nameOfMeasure: CharacterString	Number of excess items.
measureIdentification: MD_Identifier	
code: CharacterString	2
measureDescription: CharacterString	Number of items within the dataset that should not have been in the dataset.
evaluation: SampleBasedInspection	
evaluationMethodType: Evaluation-MethodTypeCode	directExternal
evaluationMethodDescription: CharacterString	Multistage sampling. Selecting enough sampling units so that the sample ratio is fulfilled. Sampling is based on weighted features.
evaluationProcedure: CI_Citation	
title: CharacterString	Annex E

Annex E (informative)

Sampling methods for evaluating data quality

E.1 Introduction

This annex provides guidelines for defining samples and devising sampling methods. For sampling for evaluating conformance to a data product specification, the ISO 2859 series and ISO 3951-1 may be applied. These documents were originally developed for non-spatial use. This annex describes how to apply the ISO 2859 series and ISO 3951-1 and other spatial sampling techniques to geographic data.

E.2 Lot and item

Lot and item are important concepts in the sampling inspection method specified in the ISO 2859 series and ISO 3951-1. A lot is the minimum unit for which quality may be evaluated. An item is the minimum unit to be inspected and should be defined by the data producer in accordance with the data product specification.

E.3 Sample size

The size of a population, and consequently the size of samples, may be defined according to different bases on items. The definition of a sample size requires an explicit indication of the items. Examples of different bases are presented in [Table E.1](#).

The difference between the perspectives is illustrated in [Figure E.1](#). The whole figure represents the data within the data quality scope. The figure depicts a possible sample area of approximately 15 % of the total data quality scope area, but only about 10 % of the curve length within the sample area, and 0 % of the vertices.

NOTE 1 The data quality scope is the area in the outer box. The sample area is the shaded box.

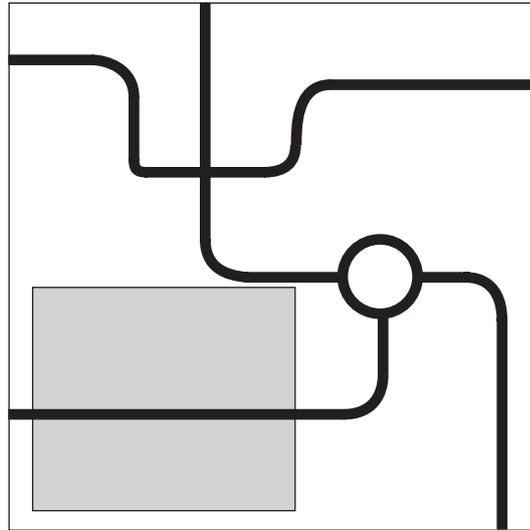

To help overcome sample difficulties such as those in [Figure E.1](#), the size and location of a sample can be defined using a combination of different criteria, thus enforcing the representativity of the sample.

NOTE 2 The data quality scope is the area in the outer box. The sample area is the shaded box.

EXAMPLE It is recommended that the sample includes 10 % of the area covered by the dataset and contains not less than 5 % of the total curve length describing the objects in the dataset.

Table E.1 — Different basis for defining population

Basis	Size of the dataset	Sample size
Features	Number of features of a given type.	Number of features of a given type expressed as a percentage of the total number of objects.
Area covered	Area covered by the dataset.	Area covered by the sample expressed as a percentage of the total area.
Curves	Total length of the curves in the dataset.	Length of the sampled curves expressed as a percentage of the total length.
Vertices	Total number of vertices describing curves or areas in the dataset.	Number of vertices in the sample expressed as a percentage of the total number of vertices.

NOTE The data quality scope is the area in the outer box. The sample area is the shaded box.

Figure E.1 — Effect of sample area location on representativity of items in the sample

E.4 Sampling strategies

E.4.1 Introduction

This clause provides guidelines for defining samples and sampling methods, considering specific aspects of geographic data. The sampling strategies described in this annex are shown graphically in [Figure E.2](#). There are two aspects to a sampling strategy: the items to be sampled (area or feature), and the manner by which the items are selected (probability or judgement).

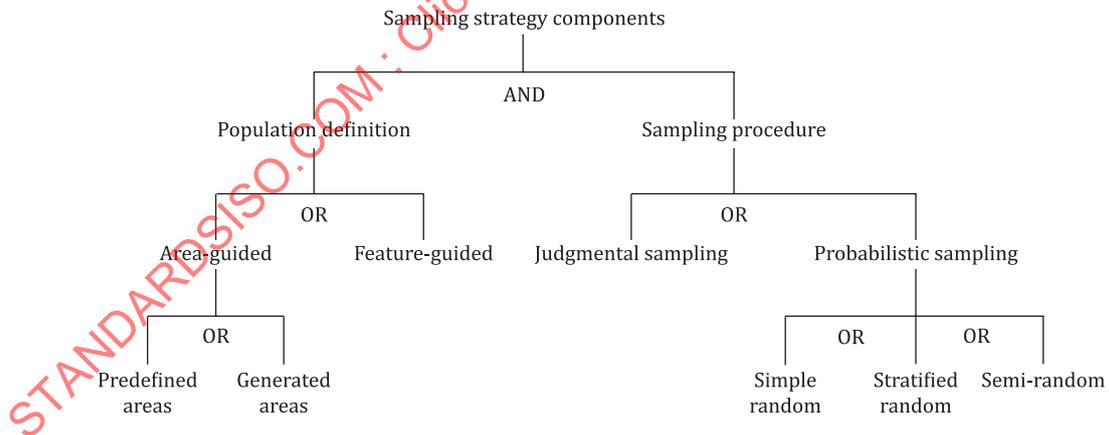

Figure E.2 — Sampling strategy relationships

E.4.2 Probabilistic versus judgemental sampling

E.4.2.1 Differences

Probabilistic sampling applies sampling theory and involves random selection of the sample items. The essential characteristic of probabilistic sampling is that each member of the population from which the sample is selected has a known probability of selection. When probabilistic sampling is used, statistical inferences may be made about the sampled population. Judgemental sample designs involve selection of samples based on expert knowledge or professional judgement.

E.4.2.2 Simple random sampling

Simple random sampling is probability-based and involves the selection of samples randomly. The particular sample (e.g. features, location, time) is selected using random numbers to identify the items and all possible selections are equally likely. Simple random sampling is useful when the population of interest is relatively homogeneous in the characteristics being sampled, i.e. no major patterns and clusters. This method may not result in representative coverage of an area, i.e. it is possible that the sample selected will be only from a part of the area.

E.4.2.3 Stratified random sampling

Stratified sampling requires the population to be separated into non-overlapping strata or subpopulations that are more homogeneous among sample items in the same strata than among sample items in different strata. This sampling strategy has the potential for greater precision in estimates of mean and variance than that of a non-stratified strategy for the same population.

E.4.2.4 Semi-random sampling

Semi-random or systematic sampling applies random selection of the initial sample items (e.g. location, time, or feature) and rules for selection for all remaining items. An example of semi-random or systematic sampling is grid sampling where the initial position of a grid is randomly determined and samples are taken at regularly spaced intervals (grid cells) over space. Systematic grid sampling is used to search for clusters and to infer means, percentiles or other parameters, and is useful for estimating spatial trends or patterns. This method provides a practical and easy way to ensure coverage of an area.

E.4.3 Feature-guided versus area-guided sampling

E.4.3.1 Feature-guided sampling (non-spatial sampling)

A feature-guided sampling strategy selects sample items based on the non-spatial attributes of the features and not on their spatial location. A sample within a data quality scope can be selected randomly, assuming homogeneous production characteristics for the entire data quality scope. In some cases, simple random sampling can potentially not produce a satisfactory sample because homogeneity is perhaps found only for subsets and homogeneous distribution of samples is perhaps required; i.e. major patterns or clusters occur in the characteristics being sampled. In that case, a stratified or semi-random sampling can potentially give better results.

NOTE If the sampling method is defined by selecting features randomly, then there is the risk of the occurrence of a sample being concentrated in a small area (which can potentially not be acceptable).

Semi-random sampling may be used to ensure the verification of different criteria on the sample size and/or location, to satisfy supplementary constraints for the samples or to reduce costs of the inspection process.

EXAMPLE A power company needs to evaluate the correctness of the attributes surveyed for features of different types. Two methods were considered: a random selection and a semi-random selection (selecting randomly the features of one type and then collecting the objects of different types in the neighbourhood of the first one until the samples for each type become fulfilled) leading to a reduced field inspection cost.

E.4.3.2 Area-guided sampling (spatial sampling)

In an area-guided sampling strategy, selection of sampling units is based on spatial considerations. The sampling units may be existing geographic areas (e.g. political or statistical areas) or some other partitioning of the universe of discourse for which the inspection is conducted. This type of sampling may be used as a first stage of sampling, followed by a feature-guided sampling within each subarea.

EXAMPLE Random selection of UTM 1 km × 1 km grid areas in order to evaluate the attributes of the objects contained in that area.

Figure E.3 illustrates the result of the definition of areas to be submitted for inspection, obtained by random generation of centre point coordinates of squares of equal area (constrained to be non-overlapping).

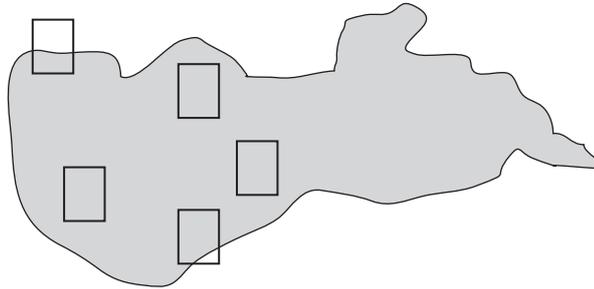

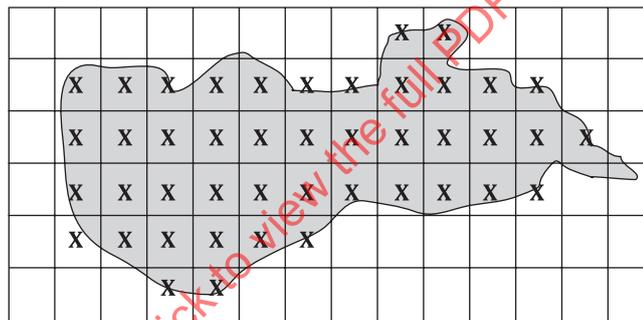

Figure E.3 — Example of area-guided random sampling

When coverage of the entire area is important, then the sample locations should be determined according to a regular or semi-regular pattern.

Figure E.4 illustrates an example of semi-random (systematic) sampling with the sampled features distributed along a regular pattern used to evaluate the positional accuracy of a dataset.

NOTE The “X” denotes the grid cells selected by rule for inclusion in the sample.

Figure E.4 — Example of area-guided regular and non-random sampling

Spatial partitioning with different sizes in different areas of the dataset may be needed in semi-random sampling, if the distribution of features is non-homogeneous. When using a grid of constant cell size, a rule is needed to include or exclude cells that are not completely inside the area of interest.

E.5 Probability-based sampling

E.5.1 General considerations

In applying sampling, the following points need to be taken into account.

- a) The areas covered by a geographic dataset can potentially form a continuous space. When splitting the dataset into lots, special attention should be paid to the omission or commission of items crossing over the lot boundaries.
- b) A variety of factors, including the quality of source data and skill of operators, can affect the quality of geographic data. The data producer should be careful to define many factors in order to achieve homogeneity in terms of quality.

Depending on the sample design, design weights (which in a probability sample corresponds to the reciprocal value of the probability of being included into the sample) may be used to define items in a sample lot.
