- Otherwise, let `C` be `remove_reference_t<COMMON-REF(X&, Y&)>&&`. If `A` and `B` are both rvalue reference types, `C` is well-formed, and `is_convertible_v<A, C> && is_convertible_v<B, C>` is true, then `COMMON-REF(A, B)` is `C`.
- Otherwise, let `D` be `COMMON-REF(const X&, Y&)`. If `A` is an rvalue reference and `B` is an lvalue reference and `D` is well-formed and `is_convertible_v<A, D>` is true, then `COMMON-REF(A, B)` is `D`.
- Otherwise, if `A` is an lvalue reference and `B` is an rvalue reference, then `COMMON-REF(A, B)` is `COMMON-REF(B, A)`.
- Otherwise, `COMMON-REF(A, B)` is ill-formed.

If any of the types computed above is ill-formed, then `COMMON-REF(A, B)` is ill-formed.

For the `common_type` trait applied to a template parameter pack `T` of types, the member `type` shall be either defined or not present as follows:

- If `sizeof...(T)` is zero, there shall be no member `type`.
- If `sizeof...(T)` is one, let `T0` denote the sole type constituting the pack `T`. The member *typedef-name* `type` shall denote the same type, if any, as `common_type_t<T0, T0>`; otherwise there shall be no member `type`.

- If `sizeof...(T)` is two, let the first and second types constituting `T` be denoted by `T1` and `T2`, respectively, and let `D1` and `D2` denote the same types as `decay_t<T1>` and `decay_t<T2>`, respectively.
 - If `is_same_v<T1, D1>` is false or `is_same_v<T2, D2>` is false, let `C` denote the same type, if any, as `common_type_t<D1, D2>`.
 - NOTE 3 None of the following will apply if there is a specialization `common_type<D1, D2>`.
 - Otherwise, if

```
decay_t<decltype(false ? declval<D1>() : declval<D2>())>
```

denotes a valid type, let `C` denote that type.
 - Otherwise, if `COND-RES(CREF(D1), CREF(D2))` denotes a type, let `C` denote the type `decay_t<COND-RES(CREF(D1), CREF(D2))>`.

In either case, the member `typedef-name type` shall denote the same type, if any, as `C`. Otherwise, there shall be no member `type`.

- If `sizeof...(T)` is greater than two, let `T1`, `T2`, and `R`, respectively, denote the first, second, and (pack of) remaining types constituting `T`. Let `C` denote the same type, if any, as `common_type_t<T1, T2>`. If there is such a type `C`, the member `typedef-name type` shall denote the same type, if any, as `common_type_t<C, R...>`. Otherwise, there shall be no member `type`.

Notwithstanding the provisions of 21.3.3, and pursuant to 16.4.5.2.1, a program may specialize `common_type<T1, T2>` for types `T1` and `T2` such that `is_same_v<T1, decay_t<T1>>` and `is_same_v<T2, decay_t<T2>>` are each true.

NOTE 4 Such specializations are needed when only explicit conversions are desired between the template arguments.

Such a specialization need not have a member named `type`, but if it does, the *qualified-id* `common_type<T1, T2>::type` shall denote a cv-unqualified non-reference type to which each of the types `T1` and `T2` is explicitly convertible. Moreover, `common_type_t<T1, T2>` shall denote the same type, if any, as does `common_type_t<T2, T1>`. No diagnostic is required for a violation of this Note's rules.

For the `common_reference` trait applied to a parameter pack `T` of types, the member `type` shall be either defined or not present as follows:

- If `sizeof...(T)` is zero, there shall be no member `type`.
- Otherwise, if `sizeof...(T)` is one, let `T0` denote the sole type in the pack `T`. The member `typedef type` shall denote the same type as `T0`.
- Otherwise, if `sizeof...(T)` is two, let `T1` and `T2` denote the two types in the pack `T`. Then
 - Let `R` be `COMMON-REF(T1, T2)`. If `T1` and `T2` are reference types, `R` is well-formed, and `is_convertible_v<add_pointer_t<T1>, add_pointer_t<R>> && is_convertible_v<add_pointer_t<T2>, add_pointer_t<R>>` is true, then the member `typedef type` denotes `R`.
 - Otherwise, if `basic_common_reference<remove_cvref_t<T1>, remove_cvref_t<T2>, XREF(T1), XREF(T2)>::type` is well-formed, then the member `typedef type` denotes that type.
 - Otherwise, if `COND-RES(T1, T2)` is well-formed, then the member `typedef type` denotes that type.
 - Otherwise, if `common_type_t<T1, T2>` is well-formed, then the member `typedef type` denotes that type.
- Otherwise, there shall be no member `type`.
- Otherwise, if `sizeof...(T)` is greater than two, let `T1`, `T2`, and `Rest`, respectively, denote the first, second, and (pack of) remaining types comprising `T`. Let `C` be the type `common_reference_t<T1, T2>`. Then:
 - If there is such a type `C`, the member `typedef type` shall denote the same type, if any, as `common_reference_t<C, Rest...>`.
 - Otherwise, there shall be no member `type`.

Notwithstanding the provisions of 21.3.3, and pursuant to 16.4.5.2.1, a program may partially specialize `basic_common_reference<T, U, TQual, UQual>` for types `T` and `U` such that `is_same_v<T, decay_t<T>>` and `is_same_v<U, decay_t<U>>` are each true.

NOTE 5 Such specializations can be used to influence the result of `common_reference`, and are needed when only explicit conversions are desired between the template arguments.

Such a specialization need not have a member named `type`, but if it does, the *qualified-id* `basic_common_reference<T, U, TQual, UQual>::type` shall denote a type to which each of the types `TQual<T>` and `UQual<U>` is convertible. Moreover, `basic_common_reference<T, U, TQual, UQual>::type` shall denote the same type, if any, as does `basic_common_reference<U, T, UQual, TQual>::type`. No diagnostic is required for a violation of these rules.

EXAMPLE 2 Given these definitions:

```
using PF1 = bool (&)();
using PF2 = short (*)(long);

struct S {
    operator PF2() const;
    double operator()(char, int&);
    void fn(long) const;
    char data;
};

using PMF = void (S::*)(long) const;
using PMD = char S::*;
```

the following assertions will hold:

```
static_assert(is_same_v<invoke_result_t<S, int>, short>);
static_assert(is_same_v<invoke_result_t<S&, unsigned char, int&>, double>);
static_assert(is_same_v<invoke_result_t<PF1>, bool>);
static_assert(is_same_v<invoke_result_t<PMF, unique_ptr<S>, int>, void>);
static_assert(is_same_v<invoke_result_t<PMD, S>, char&&>);
static_assert(is_same_v<invoke_result_t<PMD, const S*>, const char&>);
```

21.3.9 Logical operator traits

[meta.logical]

This subclause describes type traits for applying logical operators to other type traits.

```
template<class... B> struct conjunction : see below { };
```

The class template `conjunction` forms the logical conjunction of its template type arguments.

For a specialization `conjunction<B1, ..., BN>`, if there is a template type argument `Bi` for which `bool(Bi::value)` is `false`, then instantiating `conjunction<B1, ..., BN>::value` does not require the instantiation of `Bj::value` for $j > i$.

NOTE 1 This is analogous to the short-circuiting behavior of the built-in operator `&&`.

Every template type argument for which `Bi::value` is instantiated shall be usable as a base class and shall have a member `value` which is convertible to `bool`, is not hidden, and is unambiguously available in the type.

The specialization `conjunction<B1, ..., BN>` has a public and unambiguous base that is either

- the first type `Bi` in the list `true_type`, `B1, ..., BN` for which `bool(Bi::value)` is `false`, or
- if there is no such `Bi`, the last type in the list.

NOTE 2 This means a specialization of `conjunction` does not necessarily inherit from either `true_type` or `false_type`.

The member names of the base class, other than `conjunction` and `operator=`, shall not be hidden and shall be unambiguously available in `conjunction`.

```
template<class... B> struct disjunction : see below { };
```

The class template `disjunction` forms the logical disjunction of its template type arguments.

For a specialization `disjunction<B1, ..., BN>`, if there is a template type argument `Bi` for which `bool(Bi::value)` is `true`, then instantiating `disjunction<B1, ..., BN>::value` does not require the instantiation of `Bj::value` for $j > i$.

NOTE 3 This is analogous to the short-circuiting behavior of the built-in operator `||`.

Every template type argument for which `Bi::value` is instantiated shall be usable as a base class and shall have a member `value` which is convertible to `bool`, is not hidden, and is unambiguously available in the type.

The specialization `disjunction<B1, ..., BN>` has a public and unambiguous base that is either

- the first type `Bi` in the list `false_type`, `B1, ..., BN` for which `bool(Bi::value)` is `true`, or
- if there is no such `Bi`, the last type in the list.

NOTE 4 This means a specialization of `disjunction` does not necessarily inherit from either `true_type` or `false_type`.

The member names of the base class, other than `disjunction` and `operator=`, shall not be hidden and shall be unambiguously available in `disjunction`.

```
template<class B> struct negation : see below { };
```

The class template `negation` forms the logical negation of its template type argument. The type `negation<B>` is a *Cpp17UnaryTypeTrait* with a base characteristic of `bool_constant<!bool(B::value)>`.

21.3.10 Member relationships

[meta.member]

```
template<class S, class M>
constexpr bool is_pointer_interconvertible_with_class(M S::*m) noexcept;
```

Mandates: `S` is a complete type.

Returns: `true` if and only if `S` is a standard-layout type, `M` is an object type, `m` is not null, and each object `s` of type `S` is pointer-interconvertible (6.8.4) with its subobject `s.*m`.

```
template<class S1, class S2, class M1, class M2>
constexpr bool is_corresponding_member(M1 S1::*m1, M2 S2::*m2) noexcept;
```

Mandates: `S1` and `S2` are complete types.

Returns: `true` if and only if `S1` and `S2` are standard-layout struct (11.2) types, `M1` and `M2` are object types, `m1` and `m2` are not null, and `m1` and `m2` point to corresponding members of the common initial sequence (11.4) of `S1` and `S2`.

NOTE The type of a pointer-to-member expression `&C::b` is not always a pointer to member of `C`, leading to potentially surprising results when using these functions in conjunction with inheritance.

EXAMPLE

```
struct A { int a; };           // a standard-layout class
struct B { int b; };           // a standard-layout class
struct C: public A, public B { }; // not a standard-layout class

static_assert( is_pointer_interconvertible_with_class( &C::b ) );
// Succeeds because, despite its appearance, &C::b has type
// "pointer to member of B of type int".
static_assert( is_pointer_interconvertible_with_class<C>( &C::b ) );
// Forces the use of class C, and fails.

static_assert( is_corresponding_member( &C::a, &C::b ) );
// Succeeds because, despite its appearance, &C::a and &C::b have types
// "pointer to member of A of type int" and
// "pointer to member of B of type int", respectively.
static_assert( is_corresponding_member<C, C>( &C::a, &C::b ) );
// Forces the use of class C, and fails.
```

21.3.11 Constant evaluation context

[meta.const.eval]

```
constexpr bool is_constant_evaluated() noexcept;
```

Effects: Equivalent to:

```
if consteval {
    return true;
} else {
    return false;
}
```

```

using deci = ratio<1, 10>;
using deca = ratio<10, 1>;
using hecto = ratio<100, 1>;
using kilo = ratio<1'000, 1>;
using mega = ratio<1'000'000, 1>;
using giga = ratio<1'000'000'000, 1>;
using tera = ratio<1'000'000'000'000, 1>;
using peta = ratio<1'000'000'000'000'000, 1>;
using exa = ratio<1'000'000'000'000'000'000, 1>;
using zetta = ratio<1'000'000'000'000'000'000'000, 1>; // see below
using yotta = ratio<1'000'000'000'000'000'000'000'000, 1>; // see below
}

```

21.4.3 Class template ratio

[ratio.ratio]

```

namespace std {
    template<intmax_t N, intmax_t D = 1> class ratio {
    public:
        static constexpr intmax_t num;
        static constexpr intmax_t den;
        using type = ratio<num, den>;
    };
}

```

If the template argument `D` is zero or the absolute values of either of the template arguments `N` and `D` is not representable by type `intmax_t`, the program is ill-formed.

NOTE These rules ensure that infinite ratios are avoided and that for any negative input, there exists a representable value of its absolute value which is positive. This excludes the most negative value.

The static data members `num` and `den` shall have the following values, where `gcd` represents the greatest common divisor of the absolute values of `N` and `D`:

- `num` shall have the value $\text{sgn}(N) * \text{sgn}(D) * \text{abs}(N) / \text{gcd}$.
- `den` shall have the value $\text{abs}(D) / \text{gcd}$.

21.4.4 Arithmetic on ratios

[ratio.arithmetic]

Each of the alias templates `ratio_add`, `ratio_subtract`, `ratio_multiply`, and `ratio_divide` denotes the result of an arithmetic computation on two ratios `R1` and `R2`. With `X` and `Y` computed (in the absence of arithmetic overflow) as specified by Table 56, each alias denotes a `ratio<U, V>` such that `U` is the same as `ratio<X, Y>::num` and `V` is the same as `ratio<X, Y>::den`.

If it is not possible to represent `U` or `V` with `intmax_t`, the program is ill-formed. Otherwise, an implementation should yield correct values of `U` and `V`. If it is not possible to represent `X` or `Y` with `intmax_t`, the program is ill-formed unless the implementation yields correct values of `U` and `V`.

Table 56 — Expressions used to perform ratio arithmetic [tab:ratio.arithmetic]

Type	Value of X	Value of Y
<code>ratio_add<R1, R2></code>	$R1::\text{num} * R2::\text{den} + R2::\text{num} * R1::\text{den}$	$R1::\text{den} * R2::\text{den}$
<code>ratio_subtract<R1, R2></code>	$R1::\text{num} * R2::\text{den} - R2::\text{num} * R1::\text{den}$	$R1::\text{den} * R2::\text{den}$
<code>ratio_multiply<R1, R2></code>	$R1::\text{num} * R2::\text{num}$	$R1::\text{den} * R2::\text{den}$
<code>ratio_divide<R1, R2></code>	$R1::\text{num} * R2::\text{den}$	$R1::\text{den} * R2::\text{num}$

EXAMPLE

```

static_assert(ratio_add<ratio<1, 3>, ratio<1, 6>>::num == 1, "1/3+1/6 == 1/2");
static_assert(ratio_add<ratio<1, 3>, ratio<1, 6>>::den == 2, "1/3+1/6 == 1/2");
static_assert(ratio_multiply<ratio<1, 3>, ratio<3, 2>>::num == 1, "1/3*3/2 == 1/2");
static_assert(ratio_multiply<ratio<1, 3>, ratio<3, 2>>::den == 2, "1/3*3/2 == 1/2");

```

```
// The following cases may cause the program to be ill-formed under some implementations
static_assert(ratio_add<ratio<1, INT_MAX>, ratio<1, INT_MAX>>::num == 2,
    "1/MAX+1/MAX == 2/MAX");
static_assert(ratio_add<ratio<1, INT_MAX>, ratio<1, INT_MAX>>::den == INT_MAX,
    "1/MAX+1/MAX == 2/MAX");
static_assert(ratio_multiply<ratio<1, INT_MAX>, ratio<INT_MAX, 2>>::num == 1,
    "1/MAX * MAX/2 == 1/2");
static_assert(ratio_multiply<ratio<1, INT_MAX>, ratio<INT_MAX, 2>>::den == 2,
    "1/MAX * MAX/2 == 1/2");
```

21.4.5 Comparison of ratios

[ratio.comparison]

```
template<class R1, class R2>
    struct ratio_equal : bool_constant<R1::num == R2::num && R1::den == R2::den> { };
```

```
template<class R1, class R2>
    struct ratio_not_equal : bool_constant<!ratio_equal_v<R1, R2>> { };
```

```
template<class R1, class R2>
    struct ratio_less : bool_constant<see below> { };
```

If $R1::num \times R2::den$ is less than $R2::num \times R1::den$, `ratio_less<R1, R2>` shall be derived from `bool_constant<true>`; otherwise it shall be derived from `bool_constant<false>`. Implementations may use other algorithms to compute this relationship to avoid overflow. If overflow occurs, the program is ill-formed.

```
template<class R1, class R2>
    struct ratio_less_equal : bool_constant<!ratio_less_v<R2, R1>> { };
```

```
template<class R1, class R2>
    struct ratio_greater : bool_constant<ratio_less_v<R2, R1>> { };
```

```
template<class R1, class R2>
    struct ratio_greater_equal : bool_constant<!ratio_less_v<R1, R2>> { };
```

21.4.6 SI types for ratio

[ratio.si]

For each of the *typedef-names* `yocto`, `zepto`, `zetta`, and `yotta`, if both of the constants used in its specification are representable by `intmax_t`, the typedef is defined; if either of the constants is not representable by `intmax_t`, the typedef is not defined.

22 General utilities library

[utilities]

22.1 General

[utilities.general]

This Clause describes utilities that are generally useful in C++ programs; some of these utilities are used by other elements of the C++ standard library. These utilities are summarized in [Table 57](#).

Table 57 — General utilities library summary [tab:utilities.summary]

	Subclause	Header
22.2	Utility components	<utility>
22.3	Pairs	
22.4	Tuples	<tuple>
22.5	Optional objects	<optional>
22.6	Variants	<variant>
22.7	Storage for any type	<any>
22.8	Expected objects	<expected>
22.9	Fixed-size sequences of bits	<bitset>
22.10	Function objects	<functional>
22.11	Type indexes	<typeindex>
22.12	Execution policies	<execution>
22.13	Primitive numeric conversions	<charconv>
22.14	Formatting	<format>
22.15	Bit manipulation	<bit>

22.2 Utility components

[utility]

22.2.1 Header <utility> synopsis

[utility.syn]

The header <utility> contains some basic function and class templates that are used throughout the rest of the library.

```
// all freestanding
#include <compare>           // see 17.11.1
#include <initializer_list>  // see 17.10.2

namespace std {
    // 22.2.2, swap
    template<class T>
        constexpr void swap(T& a, T& b) noexcept(see below);
    template<class T, size_t N>
        constexpr void swap(T (&a)[N], T (&b)[N]) noexcept(is_nothrow_swappable_v<T>);

    // 22.2.3, exchange
    template<class T, class U = T>
        constexpr T exchange(T& obj, U&& new_val) noexcept(see below);

    // 22.2.4, forward/move
    template<class T>
        constexpr T&& forward(remove_reference_t<T>& t) noexcept;
    template<class T>
        constexpr T&& forward(remove_reference_t<T>&& t) noexcept;
    template<class T, class U>
        [[nodiscard]] constexpr auto forward_like(U&& x) noexcept -> see below;
    template<class T>
        constexpr remove_reference_t<T>&& move(T&&) noexcept;
```

```

template<class T>
constexpr conditional_t<
    !is_nothrow_move_constructible_v<T> && is_copy_constructible_v<T>, const T&, T&&>
    move_if_noexcept(T& x) noexcept;

// 22.2.5, as_const
template<class T>
constexpr add_const_t<T>& as_const(T& t) noexcept;
template<class T>
void as_const(const T&&) = delete;

// 22.2.6, declval

template<class T1, class T2>
    constexpr const T1&& get(const pair<T1, T2>&& p) noexcept;
template<class T2, class T1>
    constexpr T2& get(pair<T1, T2>& p) noexcept;
template<class T2, class T1>
    constexpr const T2& get(const pair<T1, T2>& p) noexcept;
template<class T2, class T1>
    constexpr T2&& get(pair<T1, T2>&& p) noexcept;
template<class T2, class T1>
    constexpr const T2&& get(const pair<T1, T2>&& p) noexcept;

// 22.3.5, pair piecewise construction
struct piecewise_construct_t {
    explicit piecewise_construct_t() = default;
};

```

```

inline constexpr piecewise_construct_t piecewise_construct{};
template<class... Types> class tuple;           // defined in <tuple> (22.4.2)

// in-place construction
struct in_place_t {
    explicit in_place_t() = default;
};
inline constexpr in_place_t in_place{};

template<class T>
    struct in_place_type_t {
        explicit in_place_type_t() = default;
    };
template<class T> constexpr in_place_type_t<T> in_place_type{};

template<size_t I>
    struct in_place_index_t {
        explicit in_place_index_t() = default;
    };
template<size_t I> constexpr in_place_index_t<I> in_place_index{};
}

```

22.2.2 swap

[utility.swap]

```

template<class T>
constexpr void swap(T& a, T& b) noexcept(see below);

```

Constraints: `is_move_constructible_v<T>` is true and `is_move_assignable_v<T>` is true.

Preconditions: Type `T` meets the *Cpp17MoveConstructible* (Table 31) and *Cpp17MoveAssignable* (Table 33) requirements.

Effects: Exchanges values stored in two locations.

Remarks: The exception specification is equivalent to:

```
is_nothrow_move_constructible_v<T> && is_nothrow_move_assignable_v<T>
```

```

template<class T, size_t N>
constexpr void swap(T (&a)[N], T (&b)[N]) noexcept(is_nothrow_swappable_v<T>);

```

Constraints: `is_swappable_v<T>` is true.

Preconditions: `a[i]` is swappable with `b[i]` for all `i` in the range `[0, N)`.

Effects: As if by `swap_ranges(a, a + N, b)`.

22.2.3 exchange

[utility.exchange]

```

template<class T, class U = T>
constexpr T exchange(T& obj, U&& new_val) noexcept(see below);

```

Effects: Equivalent to:

```

T old_val = std::move(obj);
obj = std::forward<U>(new_val);
return old_val;

```

Remarks: The exception specification is equivalent to:

```
is_nothrow_move_constructible_v<T> && is_nothrow_assignable_v<T&, U>
```

22.2.4 Forward/move helpers

[forward]

The library provides templated helper functions to simplify applying move semantics to an lvalue and to simplify the implementation of forwarding functions. All functions specified in this subclause are signal-safe (17.13.5).

```

template<class T> constexpr T&& forward(remove_reference_t<T>& t) noexcept;
template<class T> constexpr T&& forward(remove_reference_t<T>&& t) noexcept;

```

Mandates: For the second overload, `is_lvalue_reference_v<T>` is false.

Returns: `static_cast<T&&>(t)`.

EXAMPLE 1

```
template<class T, class A1, class A2>
shared_ptr<T> factory(A1&& a1, A2&& a2) {
    return shared_ptr<T>(new T(std::forward<A1>(a1), std::forward<A2>(a2)));
}

struct A {
    A(int&, const double&);
};

void g() {
    shared_ptr<A> sp1 = factory<A>(2, 1.414); // error: 2 will not bind to int&
    int i = 2;
    shared_ptr<A> sp2 = factory<A>(i, 1.414); // OK
}
```

In the first call to `factory`, `A1` is deduced as `int`, so `2` is forwarded to `A`'s constructor as an rvalue. In the second call to `factory`, `A1` is deduced as `int&`, so `i` is forwarded to `A`'s constructor as an lvalue. In both cases, `A2` is deduced as `double`, so `1.414` is forwarded to `A`'s constructor as an rvalue.

```
template<class T, class U>
```

```
[[nodiscard]] constexpr auto forward_like(U&& x) noexcept -> see below;
```

Mandates: `T` is a referenceable type (3.43).

- Let `COPY_CONST(A, B)` be `const B` if `A` is a `const` type, otherwise `B`.
- Let `OVERRIDE_REF(A, B)` be `remove_reference_t<B>&&` if `A` is an rvalue reference type, otherwise `B&`.
- Let `V` be

```
OVERRIDE_REF(T&&, COPY_CONST(remove_reference_t<T>, remove_reference_t<U>))
```

Returns: `static_cast<V>(x)`.

Remarks: The return type is `V`.

EXAMPLE 2

```
struct accessor {
    vector<string>* container;
    decltype(auto) operator[](this auto&& self, size_t i) {
        return std::forward_like

```

```
template<class T> constexpr remove_reference_t<T>&& move(T&& t) noexcept;
```

Returns: `static_cast<remove_reference_t<T>&&>(t)`.

EXAMPLE 3

```
template<class T, class A1>
shared_ptr<T> factory(A1&& a1) {
    return shared_ptr<T>(new T(std::forward<A1>(a1)));
}

struct A {
    A();
    A(const A&); // copies from lvalues
}
```

```

    A(A&&);           // moves from rvalues
};

void g() {
    A a;
    shared_ptr<A> sp1 = factory<A>(a);           // "a" binds to A(const A&)
    shared_ptr<A> sp2 = factory<A>(std::move(a)); // "a" binds to A(A&&)
}

```

In the first call to `factory`, `A1` is deduced as `A&`, so `a` is forwarded as a non-const lvalue. This binds to the constructor `A(const A&)`, which copies the value from `a`. In the second call to `factory`, because of the call `std::move(a)`, `A1` is deduced as `A`, so `a` is forwarded as an rvalue. This binds to the constructor `A(A&&)`, which moves the value from `a`.

```

template<class T> constexpr conditional_t<
    !is_nothrow_move_constructible_v<T> && is_copy_constructible_v<T>, const T&, T&&>
    move_if_noexcept(T& x) noexcept;

    Returns: std::move(x).

```

22.2.5 Function template `as_const`

[utility.as.const]

```
template<class T> constexpr add_const_t<T>& as_const(T& t) noexcept;
```

Returns: `t`.

22.2.6 Function template `declval`

[declval]

The library provides the function template `declval` to simplify the definition of expressions which occur as unevaluated operands (7.2.3).

```
template<class T> add_rvalue_reference_t<T> declval() noexcept; // as unevaluated operand
```

Mandates: This function is not odr-used (6.3).

Remarks: The template parameter `T` of `declval` may be an incomplete type.

EXAMPLE

```
template<class To, class From> decltype(static_cast<To>(declval<From>())) convert(From&&);
```

declares a function template `convert` which only participates in overload resolution if the type `From` can be explicitly converted to type `To`. For another example see class template `common_type` (21.3.8.7).

22.2.7 Integer comparison functions

[utility.intcmp]

```
template<class T, class U>
constexpr bool cmp_equal(T t, U u) noexcept;
```

Mandates: Both `T` and `U` are standard integer types or extended integer types (6.8.2).

Effects: Equivalent to:

```

using UT = make_unsigned_t<T>;
using UU = make_unsigned_t<U>;
if constexpr (is_signed_v<T> == is_signed_v<U>)
    return t == u;
else if constexpr (is_signed_v<T>)
    return t < 0 ? false : UT(t) == u;
else
    return u < 0 ? false : t == UU(u);

```

```
template<class T, class U>
constexpr bool cmp_not_equal(T t, U u) noexcept;
```

Effects: Equivalent to: `return !cmp_equal(t, u);`

```
template<class T, class U>
constexpr bool cmp_less(T t, U u) noexcept;
```

Mandates: Both `T` and `U` are standard integer types or extended integer types (6.8.2).

Effects: Equivalent to:

```

using UT = make_unsigned_t<T>;
using UU = make_unsigned_t<U>;
if constexpr (is_signed_v<T> == is_signed_v<U>)
    return t < u;
else if constexpr (is_signed_v<T>)
    return t < 0 ? true : UT(t) < u;
else
    return u < 0 ? false : t < UU(u);

template<class T, class U>
constexpr bool cmp_greater(T t, U u) noexcept;
Effects: Equivalent to: return cmp_less(u, t);

template<class T, class U>
constexpr bool cmp_less_equal(T t, U u) noexcept;
Effects: Equivalent to: return !cmp_greater(t, u);

template<class T, class U>
constexpr bool cmp_greater_equal(T t, U u) noexcept;
Effects: Equivalent to: return !cmp_less(t, u);

template<class R, class T>
constexpr bool in_range(T t) noexcept;
Mandates: Both T and R are standard integer types or extended integer types (6.8.2).
Effects: Equivalent to:
    return cmp_greater_equal(t, numeric_limits<R>::min()) &&
           cmp_less_equal(t, numeric_limits<R>::max());

```

NOTE These function templates are not usable for comparing `byte`, `char`, `char8_t`, `char16_t`, `char32_t`, `wchar_t`, and `bool`.

22.2.8 Function template `to_underlying` [utility.underlying]

```

template<class T>
constexpr underlying_type_t<T> to_underlying(T value) noexcept;
Returns: static_cast<underlying_type_t<T>>(value).

```

22.2.9 Function `unreachable` [utility.unreachable]

```
[[noreturn]] void unreachable();
```

Preconditions: `false` is `true`.

NOTE This precondition is never satisfied, thus the behavior of calling `unreachable` is undefined.

EXAMPLE

```

int f(int x) {
    switch (x) {
        case 0:
        case 1:
            return x;
        default:
            std::unreachable();
    }
}

int a = f(1);           // OK, a has value 1
int b = f(3);           // undefined behavior

```

22.3 Pairs [pairs]

22.3.1 General [pairs.general]

The library provides a template for heterogeneous pairs of values. The library also provides a matching function template to simplify their construction and several templates that provide access to `pair` objects as if they were tuple objects (see 22.4.7 and 22.4.8).

22.3.2 Class template pair

[pairs.pair]

```

namespace std {
    template<class T1, class T2>
    struct pair {
        using first_type = T1;
        using second_type = T2;

        T1 first;
        T2 second;

        pair(const pair&) = default;
        pair(pair&&) = default;
        constexpr explicit(see below) pair();
        constexpr explicit(see below) pair(const T1& x, const T2& y);
        template<class U1 = T1, class U2 = T2>
            constexpr explicit(see below) pair(U1&& x, U2&& y);
        template<class U1, class U2>
            constexpr explicit(see below) pair(pair<U1, U2>& p);
        template<class U1, class U2>
            constexpr explicit(see below) pair(const pair<U1, U2>& p);
        template<class U1, class U2>
            constexpr explicit(see below) pair(pair<U1, U2>&& p);
        template<class U1, class U2>
            constexpr explicit(see below) pair(const pair<U1, U2>&& p);
        template<pair-like P>
            constexpr explicit(see below) pair(P&& p);
        template<class... Args1, class... Args2>
            constexpr pair(piecewise_construct_t,
                           tuple<Args1...> first_args, tuple<Args2...> second_args);

        constexpr pair& operator=(const pair& p);
        constexpr const pair& operator=(const pair& p) const;
        template<class U1, class U2>
            constexpr pair& operator=(const pair<U1, U2>& p);
        template<class U1, class U2>
            constexpr const pair& operator=(const pair<U1, U2>& p) const;
        constexpr pair& operator=(pair&& p) noexcept(see below);
        constexpr const pair& operator=(pair&& p) const;
        template<class U1, class U2>
            constexpr pair& operator=(pair<U1, U2>&& p);
        template<class U1, class U2>
            constexpr const pair& operator=(pair<U1, U2>&& p) const;
        template<pair-like P>
            constexpr pair& operator=(P&& p);
        template<pair-like P>
            constexpr const pair& operator=(P&& p) const;

        constexpr void swap(pair& p) noexcept(see below);
        constexpr void swap(const pair& p) const noexcept(see below);
    };

    template<class T1, class T2>
        pair(T1, T2) -> pair<T1, T2>;
}

```

Constructors and member functions of `pair` do not throw exceptions unless one of the element-wise operations specified to be called for that operation throws an exception.

The defaulted move and copy constructor, respectively, of `pair` is a constexpr function if and only if all required element-wise initializations for move and copy, respectively, would be constexpr-suitable (9.2.6).

If `(is_trivially_destructible_v<T1> && is_trivially_destructible_v<T2>)` is true, then the destructor of `pair` is trivial.

`pair<T, U>` is a structural type (13.2) if `T` and `U` are both structural types. Two values `p1` and `p2` of type `pair<T, U>` are template-argument-equivalent (13.6) if and only if `p1.first` and `p2.first` are template-argument-equivalent and `p1.second` and `p2.second` are template-argument-equivalent.

```
constexpr explicit(see below) pair();
```

Constraints:

- `is_default_constructible_v<T1>` is true and
- `is_default_constructible_v<T2>` is true.

Effects: Value-initializes `first` and `second`.

Remarks: The expression inside `explicit` evaluates to `true` if and only if either `T1` or `T2` is not implicitly default-constructible.

NOTE 1 This behavior can be implemented with a trait that checks whether a `const T1&` or a `const T2&` can be initialized with `{}`.

```
constexpr explicit(see below) pair(const T1& x, const T2& y);
```

Constraints:

- `is_copy_constructible_v<T1>` is true and
- `is_copy_constructible_v<T2>` is true.

Effects: Initializes `first` with `x` and `second` with `y`.

Remarks: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<const T1&, T1> || !is_convertible_v<const T2&, T2>
```

```
template<class U1 = T1, class U2 = T2> constexpr explicit(see below) pair(U1&& x, U2&& y);
```

Constraints:

- `is_constructible_v<T1, U1>` is true and
- `is_constructible_v<T2, U2>` is true.

Effects: Initializes `first` with `std::forward<U1>(x)` and `second` with `std::forward<U2>(y)`.

Remarks: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<U1, T1> || !is_convertible_v<U2, T2>
```

This constructor is defined as deleted if `reference_constructs_from_temporary_v<first_type, U1&&>` is true or `reference_constructs_from_temporary_v<second_type, U2&&>` is true.

```
template<class U1, class U2> constexpr explicit(see below) pair(pair<U1, U2>& p);
template<class U1, class U2> constexpr explicit(see below) pair(const pair<U1, U2>& p);
template<class U1, class U2> constexpr explicit(see below) pair(pair<U1, U2>&& p);
template<class U1, class U2> constexpr explicit(see below) pair(const pair<U1, U2>&& p);
template<pair-like P> constexpr explicit(see below) pair(P&& p);
```

Let `FWD(u)` be `static_cast<decltype(u)>(u)`.

Constraints:

- For the last overload, `remove_cvref_t<P>` is not a specialization of `ranges::subrange`,
- `is_constructible_v<T1, decltype(get<0>(FWD(p)))>` is true, and
- `is_constructible_v<T2, decltype(get<1>(FWD(p)))>` is true.

Effects: Initializes `first` with `get<0>(FWD(p))` and `second` with `get<1>(FWD(p))`.

Remarks: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<decltype(get<0>(FWD(p))), T1> ||
!is_convertible_v<decltype(get<1>(FWD(p))), T2>
```

The constructor is defined as deleted if

```
reference_constructs_from_temporary_v<first_type, decltype(get<0>(FWD(p)))> ||
reference_constructs_from_temporary_v<second_type, decltype(get<1>(FWD(p)))>
```

is true.

```
template<class... Args1, class... Args2>
constexpr pair(piecewise_construct_t,
              tuple<Args1...> first_args, tuple<Args2...> second_args);
```

Mandates:

- `is_constructible_v<T1, Args1...>` is true and
- `is_constructible_v<T2, Args2...>` is true.

Effects: Initializes `first` with arguments of types `Args1...` obtained by forwarding the elements of `first_args` and initializes `second` with arguments of types `Args2...` obtained by forwarding the elements of `second_args`. (Here, forwarding an element `x` of type `U` within a `tuple` object means calling `std::forward<U>(x)`.) This form of construction, whereby constructor arguments for `first` and `second` are each provided in a separate `tuple` object, is called *piecewise construction*.

NOTE 2 If a data member of `pair` is of reference type and its initialization binds it to a temporary object, the program is ill-formed (11.9.3).

```
constexpr pair& operator=(const pair& p);
```

Effects: Assigns `p.first` to `first` and `p.second` to `second`.

Returns: `*this`.

Remarks: This operator is defined as deleted unless `is_copy_assignable_v<T1>` is true and `is_copy_assignable_v<T2>` is true.

```
constexpr const pair& operator=(const pair& p) const;
```

Constraints:

- `is_copy_assignable_v<const T1>` is true and
- `is_copy_assignable_v<const T2>` is true.

Effects: Assigns `p.first` to `first` and `p.second` to `second`.

Returns: `*this`.

```
template<class U1, class U2> constexpr pair& operator=(const pair<U1, U2>& p);
```

Constraints:

- `is_assignable_v<T1&, const U1&>` is true and
- `is_assignable_v<T2&, const U2&>` is true.

Effects: Assigns `p.first` to `first` and `p.second` to `second`.

Returns: `*this`.

```
template<class U1, class U2> constexpr const pair& operator=(const pair<U1, U2>& p) const;
```

Constraints:

- `is_assignable_v<const T1&, const U1&>` is true, and
- `is_assignable_v<const T2&, const U2&>` is true.

Effects: Assigns `p.first` to `first` and `p.second` to `second`.

Returns: `*this`.

```
constexpr pair& operator=(pair&& p) noexcept(see below);
```

Constraints:

- `is_move_assignable_v<T1>` is true and
- `is_move_assignable_v<T2>` is true.

Effects: Assigns to `first` with `std::forward<T1>(p.first)` and to `second` with `std::forward<T2>(p.second)`.

Returns: `*this`.

Remarks: The exception specification is equivalent to:

```
is_nothrow_move_assignable_v<T1> && is_nothrow_move_assignable_v<T2>
```

```
constexpr const pair& operator=(pair&& p) const;
```

Constraints:

- `is_assignable_v<const T1&, T1>` is true and
- `is_assignable_v<const T2&, T2>` is true.

Effects: Assigns `std::forward<T1>(p.first)` to `first` and `std::forward<T2>(p.second)` to `second`.

Returns: `*this`.

```
template<class U1, class U2> constexpr pair& operator=(pair<U1, U2>&& p);
```

Constraints:

- `is_assignable_v<T1&, U1>` is true and
- `is_assignable_v<T2&, U2>` is true.

Effects: Assigns to `first` with `std::forward<U1>(p.first)` and to `second` with `std::forward<U2>(p.second)`.

Returns: `*this`.

```
template<pair-like P> constexpr pair& operator=(P&& p);
```

Constraints:

- `different-from<P, pair>` (26.5.2) is true,
- `remove_cvref_t<P>` is not a specialization of `ranges::subrange`,
- `is_assignable_v<T1&, decltype(get<0>(std::forward<P>(p)))>` is true, and
- `is_assignable_v<T2&, decltype(get<1>(std::forward<P>(p)))>` is true.

Effects: Assigns `get<0>(std::forward<P>(p))` to `first` and `get<1>(std::forward<P>(p))` to `second`.

Returns: `*this`.

```
template<pair-like P> constexpr const pair& operator=(P&& p) const;
```

Constraints:

- `different-from<P, pair>` (26.5.2) is true,
- `remove_cvref_t<P>` is not a specialization of `ranges::subrange`,
- `is_assignable_v<const T1&, decltype(get<0>(std::forward<P>(p)))>` is true, and
- `is_assignable_v<const T2&, decltype(get<1>(std::forward<P>(p)))>` is true.

Effects: Assigns `get<0>(std::forward<P>(p))` to `first` and `get<1>(std::forward<P>(p))` to `second`.

Returns: `*this`.

```
template<class U1, class U2> constexpr const pair& operator=(pair<U1, U2>&& p) const;
```

Constraints:

- `is_assignable_v<const T1&, U1>` is true, and
- `is_assignable_v<const T2&, U2>` is true.

Effects: Assigns `std::forward<U1>(p.first)` to `first` and `std::forward<U2>(u.second)` to `second`.

Returns: `*this`.

```
constexpr void swap(pair& p) noexcept(see below);
```

```
constexpr void swap(const pair& p) const noexcept(see below);
```

Mandates:

- For the first overload, `is_swappable_v<T1>` is true and `is_swappable_v<T2>` is true.
- For the second overload, `is_swappable_v<const T1>` is true and `is_swappable_v<const T2>` is true.

Preconditions: `first` is swappable with (16.4.4.3) `p.first` and `second` is swappable with `p.second`.

Effects: Swaps `first` with `p.first` and `second` with `p.second`.

Remarks: The exception specification is equivalent to:

- `is_nothrow_swappable_v<T1> && is_nothrow_swappable_v<T2>` for the first overload, and
- `is_nothrow_swappable_v<const T1> && is_nothrow_swappable_v<const T2>` for the second overload.

22.3.3 Specialized algorithms

[pairs.spec]

```
template<class T1, class T2, class U1, class U2>
```

```
constexpr bool operator==(const pair<T1, T2>& x, const pair<U1, U2>& y);
```

Preconditions: Each of `decltype(x.first == y.first)` and `decltype(x.second == y.second)` models *boolean-testable*.

Returns: `x.first == y.first && x.second == y.second`.

```
template<class T1, class T2, class U1, class U2>
```

```
constexpr common_comparison_category_t<synth-three-way-result<T1, U1>,
synth-three-way-result<T2, U2>>
```

```
operator<=>(const pair<T1, T2>& x, const pair<U1, U2>& y);
```

Effects: Equivalent to:

```
if (auto c = synth-three-way(x.first, y.first); c != 0) return c;
return synth-three-way(x.second, y.second);
```

```
template<class T1, class T2>
```

```
constexpr void swap(pair<T1, T2>& x, pair<T1, T2>& y) noexcept(noexcept(x.swap(y)));
```

```
template<class T1, class T2>
```

```
constexpr void swap(const pair<T1, T2>& x, const pair<T1, T2>& y) noexcept(noexcept(x.swap(y)));
```

Constraints:

- For the first overload, `is_swappable_v<T1>` is true and `is_swappable_v<T2>` is true.
- For the second overload, `is_swappable_v<const T1>` is true and `is_swappable_v<const T2>` is true.

Effects: Equivalent to `x.swap(y)`.

```
template<class T1, class T2>
```

```
constexpr pair<unwrap_ref_decay_t<T1>, unwrap_ref_decay_t<T2>> make_pair(T1&& x, T2&& y);
```

Returns:

```
pair<unwrap_ref_decay_t<T1>,
unwrap_ref_decay_t<T2>>(std::forward<T1>(x), std::forward<T2>(y))
```

EXAMPLE In place of:

```
return pair<int, double>(5, 3.1415926); // explicit types
```

a C++ program can contain:

```
return make_pair(5, 3.1415926); // types are deduced
```

22.3.4 Tuple-like access to pair

[pair.astuple]

```
template<class T1, class T2>
```

```
struct tuple_size<pair<T1, T2>> : integral_constant<size_t, 2> { };
```

```
template<size_t I, class T1, class T2>
```

```
struct tuple_element<I, pair<T1, T2>> {
using type = see below ;
};
```

Mandates: $I < 2$.

Type: The type `T1` if `I` is 0, otherwise the type `T2`.

```

template<size_t I, class T1, class T2>
constexpr tuple_element_t<I, pair<T1, T2>>& get(pair<T1, T2>& p) noexcept;
template<size_t I, class T1, class T2>
constexpr const tuple_element_t<I, pair<T1, T2>>& get(const pair<T1, T2>& p) noexcept;
template<size_t I, class T1, class T2>
constexpr tuple_element_t<I, pair<T1, T2>>&& get(pair<T1, T2>&& p) noexcept;
template<size_t I, class T1, class T2>
constexpr const tuple_element_t<I, pair<T1, T2>>&& get(const pair<T1, T2>&& p) noexcept;

```

Mandates: $I < 2$.

Returns:

- If I is 0, returns a reference to `p.first`.
- If I is 1, returns a reference to `p.second`.

```

template<class T1, class T2>
constexpr T1& get(pair<T1, T2>& p) noexcept;
template<class T1, class T2>
constexpr const T1& get(const pair<T1, T2>& p) noexcept;
template<class T1, class T2>
constexpr T1&& get(pair<T1, T2>&& p) noexcept;
template<class T1, class T2>
constexpr const T1&& get(const pair<T1, T2>&& p) noexcept;

```

Mandates: $T1$ and $T2$ are distinct types.

Returns: A reference to `p.first`.

```

template<class T2, class T1>
constexpr T2& get(pair<T1, T2>& p) noexcept;
template<class T2, class T1>
constexpr const T2& get(const pair<T1, T2>& p) noexcept;
template<class T2, class T1>
constexpr T2&& get(pair<T1, T2>&& p) noexcept;
template<class T2, class T1>
constexpr const T2&& get(const pair<T1, T2>&& p) noexcept;

```

Mandates: $T1$ and $T2$ are distinct types.

Returns: A reference to `p.second`.

22.3.5 Piecewise construction

[pair.piecewise]

```

struct piecewise_construct_t {
    explicit piecewise_construct_t() = default;
};
inline constexpr piecewise_construct_t piecewise_construct{};

```

The struct `piecewise_construct_t` is an empty class type used as a unique type to disambiguate constructor and function overloading. Specifically, `pair` has a constructor with `piecewise_construct_t` as the first argument, immediately followed by two `tuple` (22.4) arguments used for piecewise construction of the elements of the `pair` object.

22.4 Tuples

[tuple]

22.4.1 General

[tuple.general]

Subclause 22.4 describes the tuple library that provides a tuple type as the class template `tuple` that can be instantiated with any number of arguments. Each template argument specifies the type of an element in the tuple. Consequently, tuples are heterogeneous, fixed-size collections of values. An instantiation of `tuple` with two arguments is similar to an instantiation of `pair` with the same two arguments. See 22.3.

22.4.2 Header <tuple> synopsis

[tuple.syn]

```

// all freestanding
#include <compare> // see 17.11.1

```

```

namespace std {
    // 22.4.4, class template tuple
    template<class... Types>
        class tuple;

    // 22.4.3, concept tuple-like
    template<class T>
        concept tuple-like = see below;           // exposition only
    template<class T>
        concept pair-like =                       // exposition only
            tuple-like<T> && tuple_size_v<remove_cvref_t<T>> == 2;

    // 22.4.10, common_reference related specializations
    template<tuple-like TTuple, tuple-like UTuple,
            template<class> class TQual, template<class> class UQual>
        struct basic_common_reference<TTuple, UTuple, TQual, UQual>;
    template<tuple-like TTuple, tuple-like UTuple>
        struct common_type<TTuple, UTuple>;

    // 22.4.5, tuple creation functions
    inline constexpr unspecified ignore;

    template<class... TTypes>

    constexpr void swap(tuple<Types...>& x, tuple<Types...>& y) noexcept(see below);
template<class... Types>
    constexpr void swap(const tuple<Types...>& x, const tuple<Types...>& y) noexcept(see below);

// 22.4.7, tuple helper classes
template<class T>
    constexpr size_t tuple_size_v = tuple_size<T>::value;
}

```

22.4.3 Concept *tuple-like*

[tuple.like]

```

template<class T>
    concept tuple-like = see below; // exposition only

```

A type *T* models and satisfies the exposition-only concept *tuple-like* if `remove_cvref_t<T>` is a specialization of `array`, `pair`, `tuple`, or `ranges::subrange`.

22.4.4 Class template *tuple*

[tuple.tuple]

```

namespace std {
    template<class... Types>
        class tuple {
        public:
            // 22.4.4.1, tuple construction
            constexpr explicit(see below) tuple();
            constexpr explicit(see below) tuple(const Types&...); // only if sizeof...(Types) >= 1
            template<class... UTypes>
                constexpr explicit(see below) tuple(UTypes&&...); // only if sizeof...(Types) >= 1

            tuple(const tuple&) = default;
            tuple(tuple&&) = default;

            template<class... UTypes>
                constexpr explicit(see below) tuple(tuple<UTypes...>&);
            template<class... UTypes>
                constexpr explicit(see below) tuple(const tuple<UTypes...>&);
        };
}

```

```

}

```

22.4.4.1 Construction [tuple.cnstr]

In the descriptions that follow, let i be in the range $[0, \text{sizeof} \dots (\text{Types}))$ in order, T_i be the i^{th} type in **Types**, and U_i be the i^{th} type in a template parameter pack named **UTypes**, where indexing is zero-based.

For each **tuple** constructor, an exception is thrown only if the construction of one of the types in **Types** throws an exception.

The defaulted move and copy constructor, respectively, of **tuple** is a constexpr function if and only if all required element-wise initializations for move and copy, respectively, would be constexpr-suitable (9.2.6). The defaulted move and copy constructor of **tuple<>** are constexpr functions.

If `is_trivially_destructible_v< $T_i$ >` is true for all T_i , then the destructor of **tuple** is trivial.

The default constructor of **tuple<>** is trivial.

```
constexpr explicit(see below) tuple();
```

Constraints: `is_default_constructible_v< $T_i$ >` is true for all i .

Effects: Value-initializes each element.

Remarks: The expression inside `explicit` evaluates to `true` if and only if T_i is not copy-list-initializable from an empty list for at least one i .

NOTE This behavior can be implemented with a trait that checks whether a `const  $T_i$ &` can be initialized with `{}`.

```
constexpr explicit(see below) tuple(const Types&...);
```

Constraints: $\text{sizeof} \dots (\text{Types}) \geq 1$ and $\text{is\_copy\_constructible\_v} \langle T_i \rangle$ is true for all i .

Effects: Initializes each element with the value of the corresponding parameter.

Remarks: The expression inside `explicit` is equivalent to:

```
!conjunction_v<is_convertible<const Types&, Types>...>
```

```
template<class... UTypes> constexpr explicit(see below) tuple(UTypes&&... u);
```

Let *disambiguating-constraint* be:

- $\text{negation} \langle \text{is\_same} \langle \text{remove\_cvref\_t} \langle U_0 \rangle, \text{tuple} \rangle \rangle$ if $\text{sizeof} \dots (\text{Types})$ is 1;
- otherwise, $\text{bool\_constant} \langle \neg \text{is\_same\_v} \langle \text{remove\_cvref\_t} \langle U_0 \rangle, \text{allocator\_arg\_t} \rangle \mid \mid \text{is\_same\_v} \langle \text{remove\_cvref\_t} \langle T_0 \rangle, \text{allocator\_arg\_t} \rangle \rangle$ if $\text{sizeof} \dots (\text{Types})$ is 2 or 3;
- otherwise, `true_type`.

Constraints:

- $\text{sizeof} \dots (\text{Types})$ equals $\text{sizeof} \dots (\text{UTypes})$,
- $\text{sizeof} \dots (\text{Types}) \geq 1$, and
- $\text{conjunction\_v} \langle \text{disambiguating-constraint}, \text{is\_constructible} \langle \text{Types}, \text{UTypes} \rangle \dots \rangle$ is true.

Effects: Initializes the elements in the tuple with the corresponding value in `std::forward<UTypes>(u)`.

Remarks: The expression inside `explicit` is equivalent to:

```
!conjunction_v<is_convertible<UTypes, Types>...>
```

This constructor is defined as deleted if

```
(reference_constructs_from_temporary_v<Types, UTypes&&> || ...)
```

is true.

```
tuple(const tuple& u) = default;
```

Mandates: $\text{is\_copy\_constructible\_v} \langle T_i \rangle$ is true for all i .

Effects: Initializes each element of `*this` with the corresponding element of `u`.

```
tuple(tuple&& u) = default;
```

Constraints: $\text{is\_move\_constructible\_v} \langle T_i \rangle$ is true for all i .

Effects: For all i , initializes the i^{th} element of `*this` with `std::forward<Ti>(get<i>(u))`.

```
template<class... UTypes> constexpr explicit(see below) tuple(tuple<UTypes...>& u);
template<class... UTypes> constexpr explicit(see below) tuple(const tuple<UTypes...>& u);
template<class... UTypes> constexpr explicit(see below) tuple(tuple<UTypes...>&& u);
template<class... UTypes> constexpr explicit(see below) tuple(const tuple<UTypes...>&& u);
```

Let I be the pack $0, 1, \dots, (\text{sizeof} \dots (\text{Types}) - 1)$.

Let $FWD(u)$ be `static_cast<decltype(u)>(u)`.

Constraints:

- $\text{sizeof} \dots (\text{Types})$ equals $\text{sizeof} \dots (\text{UTypes})$, and
- $(\text{is\_constructible\_v} \langle \text{Types}, \text{decltype}(\text{get} \langle I \rangle (FWD(u))) \rangle \ \&\& \dots)$ is true, and
- either $\text{sizeof} \dots (\text{Types})$ is not 1, or (when `Types...` expands to `T` and `UTypes...` expands to `U`) $\text{is\_convertible\_v} \langle \text{decltype}(u), T \rangle, \text{is\_constructible\_v} \langle T, \text{decltype}(u) \rangle$, and $\text{is\_same\_v} \langle T, U \rangle$ are all false.

Effects: For all i , initializes the i^{th} element of `*this` with `get<i>(FWD(u))`.

Remarks: The expression inside `explicit` is equivalent to:

```
!(is_convertible_v<decltype(get<I>(FWD(u))), Types> && ...)
```

The constructor is defined as deleted if

```
(reference_constructs_from_temporary_v<Types, decltype(get<I>(FWD(u)))> || ...)
```

is true.

```
template<class U1, class U2> constexpr explicit(see below) tuple(pair<U1, U2>& u);
template<class U1, class U2> constexpr explicit(see below) tuple(const pair<U1, U2>& u);
template<class U1, class U2> constexpr explicit(see below) tuple(pair<U1, U2>&& u);
template<class U1, class U2> constexpr explicit(see below) tuple(const pair<U1, U2>&& u);
```

Let *FWD*(*u*) be `static_cast<decltype(u)>(u)`.

Constraints:

- `sizeof...(Types)` is 2,
- `is_constructible_v<T0, decltype(get<0>(FWD(u)))>` is true, and
- `is_constructible_v<T1, decltype(get<1>(FWD(u)))>` is true.

Effects: Initializes the first element with `get<0>(FWD(u))` and the second element with `get<1>(FWD(u))`.

Remarks: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<decltype(get<0>(FWD(u))), T0> ||
!is_convertible_v<decltype(get<1>(FWD(u))), T1>
```

The constructor is defined as deleted if

```
reference_constructs_from_temporary_v<T0, decltype(get<0>(FWD(u)))> ||
reference_constructs_from_temporary_v<T1, decltype(get<1>(FWD(u)))>
```

is true.

```
template<tuple-like UTuple>
constexpr explicit(see below) tuple(UTuple&& u);
```

Let *I* be the pack 0, 1, ..., (`sizeof...(Types)` - 1).

Constraints:

- `different-from<UTuple, tuple>` (26.5.2) is true,
- `remove_cvref_t<UTuple>` is not a specialization of `ranges::subrange`,
- `sizeof...(Types)` equals `tuple_size_v<remove_cvref_t<UTuple>>`,
- `(is_constructible_v<Types, decltype(get<I>(std::forward<UTuple>(u)))> && ...)` is true, and
- either `sizeof...(Types)` is not 1, or (when `Types...` expands to *T*) `is_convertible_v<UTuple, T>` and `is_constructible_v<T, UTuple>` are both false.

Effects: For all *i*, initializes the *i*th element of `*this` with `get<i>(std::forward<UTuple>(u))`.

Remarks: The expression inside `explicit` is equivalent to:

```
!(is_convertible_v<decltype(get<I>(std::forward<UTuple>(u))), Types> && ...)
```

```
template<class Alloc>
constexpr explicit(see below)
tuple(allocator_arg_t, const Alloc& a);
template<class Alloc>
constexpr explicit(see below)
tuple(allocator_arg_t, const Alloc& a, const Types&...);
template<class Alloc, class... UTypes>
constexpr explicit(see below)
tuple(allocator_arg_t, const Alloc& a, UTypes&&...);
template<class Alloc>
constexpr tuple(allocator_arg_t, const Alloc& a, const tuple&);
template<class Alloc>
constexpr tuple(allocator_arg_t, const Alloc& a, tuple&&);
template<class Alloc, class... UTypes>
constexpr explicit(see below)
tuple(allocator_arg_t, const Alloc& a, tuple<UTypes...>&);
```

```

template<class Alloc, class... UTypes>
constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, const tuple<UTypes...>&);
template<class Alloc, class... UTypes>
constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, tuple<UTypes...>&&);
template<class Alloc, class... UTypes>
constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, const tuple<UTypes...>&&);
template<class Alloc, class U1, class U2>
constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, pair<U1, U2>&);
template<class Alloc, class U1, class U2>
constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, const pair<U1, U2>&);
template<class Alloc, class U1, class U2>
constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, pair<U1, U2>&&);
template<class Alloc, class U1, class U2>
constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, const pair<U1, U2>&&);
template<class Alloc, tuple-like UTuple>
constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, UTuple&&);

```

Preconditions: Alloc meets the *Cpp17Allocator* requirements (16.4.4.6.1).

Effects: Equivalent to the preceding constructors except that each element is constructed with *uses-allocator* construction (20.2.8.2).

22.4.4.2 Assignment

[*tuple.assign*]

For each *tuple* assignment operator, an exception is thrown only if the assignment of one of the types in *Types* throws an exception. In the function descriptions that follow, let *i* be in the range $[0, \text{sizeof} \dots (\text{Types}))$ in order, T_i be the i^{th} type in *Types*, and U_i be the i^{th} type in a template parameter pack named *UTypes*, where indexing is zero-based.

```
constexpr tuple& operator=(const tuple& u);
```

Effects: Assigns each element of *u* to the corresponding element of **this*.

Returns: **this*.

Remarks: This operator is defined as deleted unless *is_copy_assignable_v<T_i>* is true for all *i*.

```
constexpr const tuple& operator=(const tuple& u) const;
```

Constraints: (*is_copy_assignable_v<const Types> && ...*) is true.

Effects: Assigns each element of *u* to the corresponding element of **this*.

Returns: **this*.

```
constexpr tuple& operator=(tuple&& u) noexcept(see below);
```

Constraints: *is_move_assignable_v<T_i>* is true for all *i*.

Effects: For all *i*, assigns *std::forward<T_i>(get< i >(u))* to *get< i >(*this)*.

Returns: **this*.

Remarks: The exception specification is equivalent to the logical AND of the following expressions:

is_nothrow_move_assignable_v<T_i>

where T_i is the i^{th} type in *Types*.

```
constexpr const tuple& operator=(tuple&& u) const;
```

Constraints: (*is_assignable_v<const Types&, Types> && ...*) is true.

Effects: For all *i*, assigns *std::forward<T_i>(get< i >(u))* to *get< i >(*this)*.

Returns: **this*.

```
template<class... UTypes> constexpr tuple& operator=(const tuple<UTypes...>& u);
```

Constraints:

- sizeof...(Types) equals sizeof...(UTypes) and
- is_assignable_v<T_i&, const U_i> is true for all *i*.

Effects: Assigns each element of *u* to the corresponding element of **this*.

Returns: **this*.

```
template<class... UTypes> constexpr const tuple& operator=(const tuple<UTypes...>& u) const;
```

Constraints:

- sizeof...(Types) equals sizeof...(UTypes) and
- (is_assignable_v<const Types&, const UTypes&> && ...) is true.

Effects: Assigns each element of *u* to the corresponding element of **this*.

Returns: **this*.

```
template<class... UTypes> constexpr tuple& operator=(tuple<UTypes...>&& u);
```

Constraints:

- sizeof...(Types) equals sizeof...(UTypes) and
- is_assignable_v<T_i&, U_i> is true for all *i*.

Effects: For all *i*, assigns std::forward<U_i>(get<*i*>(u)) to get<*i*>(*this).

Returns: **this*.

```
template<class... UTypes> constexpr const tuple& operator=(tuple<UTypes...>&& u) const;
```

Constraints:

- sizeof...(Types) equals sizeof...(UTypes) and
- (is_assignable_v<const Types&, UTypes> && ...) is true.

Effects: For all *i*, assigns std::forward<U_i>(get<*i*>(u)) to get<*i*>(*this).

Returns: **this*.

```
template<class U1, class U2> constexpr tuple& operator=(const pair<U1, U2>& u);
```

Constraints:

- sizeof...(Types) is 2 and
- is_assignable_v<T₀&, const U1& is true, and
- is_assignable_v<T₁&, const U2& is true.

Effects: Assigns *u.first* to the first element of **this* and *u.second* to the second element of **this*.

Returns: **this*.

```
template<class U1, class U2> constexpr const tuple& operator=(const pair<U1, U2>& u) const;
```

Constraints:

- sizeof...(Types) is 2,
- is_assignable_v<const T₀&, const U1& is true, and
- is_assignable_v<const T₁&, const U2& is true.

Effects: Assigns *u.first* to the first element and *u.second* to the second element.

Returns: **this*.

```
template<class U1, class U2> constexpr tuple& operator=(pair<U1, U2>&& u);
```

Constraints:

- sizeof...(Types) is 2 and
- is_assignable_v<T₀&, U1> is true, and

— `is_assignable_v<T1&, U2>` is true.

Effects: Assigns `std::forward<U1>(u.first)` to the first element of `*this` and `std::forward<U2>(u.second)` to the second element of `*this`.

Returns: `*this`.

```
template<class U1, class U2> constexpr const tuple& operator=(pair<U1, U2>&& u) const;
```

Constraints:

- `sizeof...(Types)` is 2,
- `is_assignable_v<const T0&, U1>` is true, and
- `is_assignable_v<const T1&, U2>` is true.

Effects: Assigns `std::forward<U1>(u.first)` to the first element and `std::forward<U2>(u.second)` to the second element.

Returns: `*this`.

```
template<tuple-like UTuple>
constexpr tuple& operator=(UTuple&& u);
```

Constraints:

- `different-from<UTuple, tuple>` (26.5.2) is true,
- `remove_cvref_t<UTuple>` is not a specialization of `ranges::subrange`,
- `sizeof...(Types)` equals `tuple_size_v<remove_cvref_t<UTuple>>`, and,
- `is_assignable_v<Ti&, decltype(get<i>(std::forward<UTuple>(u)))>` is true for all *i*.

Effects: For all *i*, assigns `get<i>(std::forward<UTuple>(u))` to `get<i>(*this)`.

Returns: `*this`.

```
template<tuple-like UTuple>
constexpr const tuple& operator=(UTuple&& u) const;
```

Constraints:

- `different-from<UTuple, tuple>` (26.5.2) is true,
- `remove_cvref_t<UTuple>` is not a specialization of `ranges::subrange`,
- `sizeof...(Types)` equals `tuple_size_v<remove_cvref_t<UTuple>>`, and,
- `is_assignable_v<const Ti&, decltype(get<i>(std::forward<UTuple>(u)))>` is true for all *i*.

Effects: For all *i*, assigns `get<i>(std::forward<UTuple>(u))` to `get<i>(*this)`.

Returns: `*this`.

22.4.4.3 swap

[tuple.swap]

```
constexpr void swap(tuple& rhs) noexcept(see below);
constexpr void swap(const tuple& rhs) const noexcept(see below);
```

Let *i* be in the range `[0, sizeof...(Types))` in order.

Mandates:

- For the first overload, `(is_swappable_v<Types> && ...)` is true.
- For the second overload, `(is_swappable_v<const Types> && ...)` is true.

Preconditions: For all *i*, `get<i>(*this)` is swappable with (16.4.4.3) `get<i>(rhs)`.

Effects: For each *i*, calls `swap` for `get<i>(*this)` with `get<i>(rhs)`.

Throws: Nothing unless one of the element-wise `swap` calls throws an exception.

Remarks: The exception specification is equivalent to

- `(is_nothrow_swappable_v<Types> && ...)` for the first overload and
- `(is_nothrow_swappable_v<const Types> && ...)` for the second overload.

22.4.5 Tuple creation functions

[tuple.creation]

```
template<class... TTypes>
constexpr tuple<unwrap_ref_decay_t<TTypes>...> make_tuple(TTypes&&... t);
```

Returns: tuple<unwrap_ref_decay_t<TTypes>...>(std::forward<TTypes>(t)...).

EXAMPLE 1

```
int i; float j;
make_tuple(1, ref(i), cref(j));
```

creates a tuple of type tuple<int, int&, const float&>.

```
template<class... TTypes>
constexpr tuple<TTypes&&...> forward_as_tuple(TTypes&&... t) noexcept;
```

Effects: Constructs a tuple of references to the arguments in *t* suitable for forwarding as arguments to a function. Because the result may contain references to temporary objects, a program shall ensure that the return value of this function does not outlive any of its arguments (e.g., the program should typically not store the result in a named variable).

Returns: tuple<TTypes&&...>(std::forward<TTypes>(t)...).

```
template<class... TTypes>
constexpr tuple<TTypes&...> tie(TTypes&... t) noexcept;
```

Returns: tuple<TTypes&...>(t...). When an argument in *t* is *ignore*, assigning any value to the corresponding tuple element has no effect.

EXAMPLE 2 *tie* functions allow one to create tuples that unpack tuples into variables. *ignore* can be used for elements that are not needed:

```
int i; std::string s;
tie(i, ignore, s) = make_tuple(42, 3.14, "C++");
// i == 42, s == "C++"
```

```
template<tuple-like... Tuples>
constexpr tuple<CTypes...> tuple_cat(Tuples&&... tpls);
```

Let n be `sizeof...(Tuples)`. For every integer $0 \leq i < n$:

- Let T_i be the i^{th} type in *Tuples*.
- Let U_i be `remove_cvref_t< $T_i$ >`.
- Let tp_i be the i^{th} element in the function parameter pack *tpls*.
- Let S_i be `tuple_size_v< $U_i$ >`.
- Let E_i^k be `tuple_element_t< $k$ ,  $U_i$ >`.
- Let e_i^k be `get< $k$ >(std::forward< $T_i$ >(tpi))`.
- Let $Elms_i$ be a pack of the types $E_i^0, \dots, E_i^{S_i-1}$.
- Let $elems_i$ be a pack of the expressions $e_i^0, \dots, e_i^{S_i-1}$.

The types in *CTypes* are equal to the ordered sequence of the expanded packs of types $Elms_0, \dots, Elms_1, \dots, \dots, Elms_{n-1}, \dots$. Let *celems* be the ordered sequence of the expanded packs of expressions $elems_0, \dots, elems_{n-1}, \dots$.

Mandates: (`is_constructible_v<CTypes, decltype(celems)> && ...`) is true.

Returns: tuple<CTypes...>(celems...).

22.4.6 Calling a function with a tuple of arguments

[tuple.apply]

```
template<class F, tuple-like Tuple>
constexpr decltype(auto) apply(F&& f, Tuple&& t) noexcept(see below);
```

Effects: Given the exposition-only function:

```
namespace std {
    template<class F, tuple-like Tuple, size_t... I>
    constexpr decltype(auto) apply_impl(F&& f, Tuple&& t, index_sequence<I...>) {
        // exposition only
    }
}
```

```

    return INVOKE(std::forward<F>(f), get<I>(std::forward<Tuple>(t))...);    // see 22.10.4
}
}

```

Equivalent to:

```

return apply-impl(std::forward<F>(f), std::forward<Tuple>(t),
    make_index_sequence<tuple_size_v<remove_reference_t<Tuple>>>{}>);

```

Remarks: Let I be the pack $0, 1, \dots, (\text{tuple\_size\_v}<\text{remove\_reference\_t}<\text{Tuple}>> - 1)$. The exception specification is equivalent to:

```

noexcept(invoker(std::forward<F>(f), get<I>(std::forward<Tuple>(t))...))

```

```

template<class T, tuple-like Tuple>
constexpr T make_from_tuple(Tuple&& t);

```

Mandates: If $\text{tuple\_size\_v}<\text{remove\_reference\_t}<\text{Tuple}>>$ is 1, then $\text{reference\_constructs\_from\_temporary\_v}<\text{T}, \text{decltype}(\text{get}<0>(\text{declval}<\text{Tuple}>()))>$ is false.

Effects: Given the exposition-only function:

```

namespace std {
    template<class T, tuple-like Tuple, size_t... I>
        requires is_constructible_v<T, decltype(get<I>(declval<Tuple>()))...>
        constexpr T make-from-tuple-impl(Tuple&& t, index_sequence<I...>) {    // exposition only
            return T(get<I>(std::forward<Tuple>(t))...);
        }
}

```

Equivalent to:

```

return make-from-tuple-impl<T>(
    std::forward<Tuple>(t),
    make_index_sequence<tuple_size_v<remove_reference_t<Tuple>>>{}>);

```

NOTE As the type T cannot be deduced from the argument list, it is necessary for it to be supplied as an explicit template argument.

22.4.7 Tuple helper classes

[tuple.helper]

```

template<class T> struct tuple_size;

```

All specializations of `tuple_size` meet the *Cpp17UnaryTypeTrait* requirements (21.3.2) with a base characteristic of `integral_constant<size_t, N>` for some N .

```

template<class... Types>
struct tuple_size<tuple<Types...>> : public integral_constant<size_t, sizeof...(Types)> { };

```

```

template<size_t I, class... Types>
struct tuple_element<I, tuple<Types...>> {
    using type = TI;
};

```

Mandates: $I < \text{sizeof} \dots (\text{Types})$.

Type: T_I is the type of the I^{th} element of `Types`, where indexing is zero-based.

```

template<class T> struct tuple_size<const T>;

```

Let TS denote `tuple_size<T>` of the cv-unqualified type T . If the expression $TS::\text{value}$ is well-formed when treated as an unevaluated operand (7.2.3), then each specialization of the template meets the *Cpp17UnaryTypeTrait* requirements (21.3.2) with a base characteristic of

```

integral_constant<size_t, TS::value>

```

Otherwise, it has no member `value`.

Access checking is performed as if in a context unrelated to TS and T . Only the validity of the immediate context of the expression is considered.

NOTE The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed.

In addition to being available via inclusion of the `<tuple>` header, the template is available when any of the headers `<array>` (24.3.2), `<ranges>` (26.2), or `<utility>` (22.2.1) are included.

```
template<size_t I, class T> struct tuple_element<I, const T>;
```

Let TE denote `tuple_element_t<I, T>` of the cv-unqualified type T. Then each specialization of the template meets the *Cpp17TransformationTrait* requirements (21.3.2) with a member typedef `type` that names the type `add_const_t<TE>`.

In addition to being available via inclusion of the `<tuple>` header, the template is available when any of the headers `<array>` (24.3.2), `<ranges>` (26.2), or `<utility>` (22.2.1) are included.

22.4.8 Element access

[tuple.elem]

```
template<size_t I, class... Types>
constexpr tuple_element_t<I, tuple<Types...>>&
get(tuple<Types...>& t) noexcept;
template<size_t I, class... Types>
constexpr tuple_element_t<I, tuple<Types...>>&&
get(tuple<Types...>&& t) noexcept; // #1
template<size_t I, class... Types>
constexpr const tuple_element_t<I, tuple<Types...>>&
get(const tuple<Types...>& t) noexcept; // #2
template<size_t I, class... Types>
constexpr const tuple_element_t<I, tuple<Types...>>&& get(const tuple<Types...>&& t) noexcept;
```

Mandates: $I < \text{sizeof} \dots (\text{Types})$.

Returns: A reference to the I^{th} element of `t`, where indexing is zero-based.

NOTE 1 For the overload marked #1, if a type T in `Types` is some reference type `X&`, the return type is `X&`, not `X&&`. However, if the element type is a non-reference type T, the return type is `T&&`.

NOTE 2 Constness is shallow. For the overload marked #2, if a type T in `Types` is some reference type `X&`, the return type is `X&`, not `const X&`. However, if the element type is a non-reference type T, the return type is `const T&`. This is consistent with how constness is defined to work for non-static data members of reference type.

```
template<class T, class... Types>
constexpr T& get(tuple<Types...>& t) noexcept;
template<class T, class... Types>
constexpr T&& get(tuple<Types...>&& t) noexcept;
template<class T, class... Types>
constexpr const T& get(const tuple<Types...>& t) noexcept;
template<class T, class... Types>
constexpr const T&& get(const tuple<Types...>&& t) noexcept;
```

Mandates: The type T occurs exactly once in `Types`.

Returns: A reference to the element of `t` corresponding to the type T in `Types`.

EXAMPLE

```
const tuple<int, const int, double, double> t(1, 2, 3.4, 5.6);
const int& i1 = get<int>(t); // OK, i1 has value 1
const int& i2 = get<const int>(t); // OK, i2 has value 2
const double& d = get<double>(t); // error: type double is not unique within t
```

NOTE 3 The reason `get` is a non-member function is that if this functionality had been provided as a member function, code where the type depended on a template parameter would have required using the `template` keyword.

22.4.9 Relational operators

[tuple.rel]

```
template<class... TTypes, class... UTypes>
constexpr bool operator==(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
template<class... TTypes, tuple-like UTuple>
constexpr bool operator==(const tuple<TTypes...>& t, const UTuple& u);
```

For the first overload let `UTuple` be `tuple<UTypes...>`.

Mandates: For all i , where $0 \leq i < \text{sizeof} \dots (\text{TTypes})$, `get<i>(t) == get<i>(u)` is a valid expression. `sizeof... (TTypes)` equals `tuple_size_v<UTuple>`.

Preconditions: For all i , `decltype(get<i>(t)) == get<i>(u)` models *boolean-testable*.

Returns: `true` if `get<i>(t) == get<i>(u)` for all i , otherwise `false`.

NOTE 1 If `sizeof...(TTypes)` equals zero, returns `true`.

Remarks:

- The elementary comparisons are performed in order from the zeroth index upwards. No comparisons or element accesses are performed after the first equality comparison that evaluates to `false`.
- The second overload is to be found via argument-dependent lookup (6.5.4) only.

```
template<class... TTypes, class... UTypes>
constexpr common_comparison_category_t<synth-three-way-result<TTypes, UTypes>...>
operator<=>(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
template<class... TTypes, tuple-like UTuple>
constexpr common_comparison_category_t<synth-three-way-result<TTypes, Elms>...>
operator<=>(const tuple<TTypes...>& t, const UTuple& u);
```

For the second overload, `Elms` denotes the pack of types `tuple_element_t<0, UTuple>`, `tuple_element_t<1, UTuple>`, ..., `tuple_element_t<tuple_size_v<UTuple> - 1, UTuple>`.

Effects: Performs a lexicographical comparison between `t` and `u`. If `sizeof...(TTypes)` equals zero, returns `strong_ordering::equal`. Otherwise, equivalent to:

```
if (auto c = synth-three-way(get<0>(t), get<0>(u)); c != 0) return c;
return t_tail <=> u_tail;
```

where `rtail` for some `r` is a tuple containing all but the first element of `r`.

Remarks: The second overload is to be found via argument-dependent lookup (6.5.4) only.

NOTE 2 The above definition does not require `ttail` (or `utail`) to be constructed; this is impossible if `t` or `u` is not copy-constructible. Also, all comparison operator functions are short circuited; they do not perform element accesses beyond what is needed to determine the result of the comparison.

22.4.10 common_reference related specializations

[tuple.common.ref]

In the descriptions that follow:

- Let `TTypes` be a pack formed by the sequence of `tuple_element_t<i, TTuple>` for every integer $0 \leq i < \text{tuple\_size\_v}<\text{TTuple}>$.
- Let `UTypes` be a pack formed by the sequence of `tuple_element_t<i, UTuple>` for every integer $0 \leq i < \text{tuple\_size\_v}<\text{UTuple}>$.

```
template<tuple-like TTuple, tuple-like UTuple,
        template<class> class TQual, template<class> class UQual>
struct basic_common_reference<TTuple, UTuple, TQual, UQual> {
    using type = see below;
};
```

Constraints:

- `TTuple` is a specialization of `tuple` or `UTuple` is a specialization of `tuple`.
- `is_same_v<TTuple, decay_t<TTuple>>` is true.
- `is_same_v<UTuple, decay_t<UTuple>>` is true.
- `tuple_size_v<TTuple>` equals `tuple_size_v<UTuple>`.
- `tuple<common_reference_t<TQual<TTypes>, UQual<UTypes>>...>` denotes a type.

The member *typedef-name* `type` denotes the type `tuple<common_reference_t<TQual<TTypes>, UQual<UTypes>>...>`.

```
template<tuple-like TTuple, tuple-like UTuple>
struct common_type<TTuple, UTuple> {
    using type = see below;
};
```

Constraints:

- `TTuple` is a specialization of `tuple` or `UTuple` is a specialization of `tuple`.

- `is_same_v<TTuple, decay_t<TTuple>>` is true.
- `is_same_v<UTuple, decay_t<UTuple>>` is true.
- `tuple_size_v<TTuple>` equals `tuple_size_v<UTuple>`.
- `tuple<common_type_t<TTypes, UTypes>...>` denotes a type.

The member *typedef-name* type denotes the type `tuple<common_type_t<TTypes, UTypes>...>`.

22.4.11 Tuple traits

[tuple.traits]

```
template<class... Types, class Alloc>
struct uses_allocator<tuple<Types...>, Alloc> : true_type { };
```

Preconditions: Alloc meets the *Cpp17Allocator* requirements (16.4.4.6.1).

NOTE Specialization of this trait informs other library components that `tuple` can be constructed with an allocator, even though it does not have a nested `allocator_type`.

22.4.12 Tuple specialized algorithms

[tuple.special]

```
template<class... Types>
constexpr void swap(tuple<Types...>& x, tuple<Types...>& y) noexcept(see below);
template<class... Types>
constexpr void swap(const tuple<Types...>& x, const tuple<Types...>& y) noexcept(see below);
```

Constraints:

- For the first overload, `(is_swappable_v<Types> && ...)` is true.
- For the second overload, `(is_swappable_v<const Types> && ...)` is true.

Effects: As if by `x.swap(y)`.

Remarks: The exception specification is equivalent to:

```
noexcept(x.swap(y))
```

22.5 Optional objects

[optional]

22.5.1 General

[optional.general]

Subclause 22.5 describes class template `optional` that represents optional objects. An *optional object* is an object that contains the storage for another object and manages the lifetime of this contained object, if any. The contained object may be initialized after the optional object has been initialized, and may be destroyed before the optional object has been destroyed. The initialization state of the contained object is tracked by the optional object.

22.5.2 Header <optional> synopsis

[optional.syn]

```
#include <compare> // see 17.11.1

namespace std {
    // 22.5.3, class template optional
    template<class T>
    class optional;

    template<class T>
    concept is-derived-from-optional = requires(const T& t) { // exposition only
        [<class U>(const optional<U>&){ }(t);
    };

    // 22.5.4, no-value state indicator
    struct nullopt_t{see below};
    inline constexpr nullopt_t nullopt(unspecified);

    // 22.5.5, class bad_optional_access
    class bad_optional_access;
```

```

// 22.5.6, relational operators
template<class T, class U>
    constexpr bool operator==(const optional<T>&, const optional<U>&);
template<class T, class U>
    constexpr bool operator!=(const optional<T>&, const optional<U>&);
template<class T, class U>
    constexpr bool operator<(const optional<T>&, const optional<U>&);
template<class T, class U>
    constexpr bool operator>(const optional<T>&, const optional<U>&);
template<class T, class U>
    constexpr bool operator<=(const optional<T>&, const optional<U>&);
template<class T, class U>
    constexpr bool operator>=(const optional<T>&, const optional<U>&);
template<class T, three_way_comparable_with<T> U>
    constexpr compare_three_way_result_t<T, U>
        operator<=>(const optional<T>&, const optional<U>&);

// 22.5.7, comparison with nullopt
template<class T> constexpr bool operator==(const optional<T>&, nullopt_t) noexcept;
template<class T>
    constexpr strong_ordering operator<=>(const optional<T>&, nullopt_t) noexcept;

// 22.5.8, comparison with T
template<class T, class U> constexpr bool operator==(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator==(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator!=(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator!=(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator<(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator<(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator>(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator>(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator<=(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator<=(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator>=(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator>=(const T&, const optional<U>&);
template<class T, class U>
    requires (!is-derived-from-optional<U>) && three_way_comparable_with<T, U>
    constexpr compare_three_way_result_t<T, U>
        operator<=>(const optional<T>&, const U&);

// 22.5.9, specialized algorithms
template<class T>
    constexpr void swap(optional<T>&, optional<T>&) noexcept(see below);

template<class T>
    constexpr optional<see below> make_optional(T&&);
template<class T, class... Args>
    constexpr optional<T> make_optional(Args&&... args);
template<class T, class U, class... Args>
    constexpr optional<T> make_optional(initializer_list<U> il, Args&&... args);

// 22.5.10, hash support
template<class T> struct hash;
template<class T> struct hash<optional<T>>;
}

```

22.5.3 Class template optional

[optional.optional]

22.5.3.1 General

[optional.optional.general]

```

namespace std {
    template<class T>
    class optional {
    public:
        using value_type = T;

```

```

// 22.5.3.2, constructors
constexpr optional() noexcept;
constexpr optional(nullopt_t) noexcept;
constexpr optional(const optional&);
constexpr optional(optional&&) noexcept(see below);
template<class... Args>
    constexpr explicit optional(in_place_t, Args&&...);
template<class U, class... Args>
    constexpr explicit optional(in_place_t, initializer_list<U>, Args&&...);
template<class U = T>
    constexpr explicit(see below) optional(U&&);
template<class U>
    constexpr explicit(see below) optional(const optional<U>&);
template<class U>
    constexpr explicit(see below) optional(optional<U>&&);

// 22.5.3.3, destructor
constexpr ~optional();

// 22.5.3.4, assignment
constexpr optional& operator=(nullopt_t) noexcept;
constexpr optional& operator=(const optional&);
constexpr optional& operator=(optional&&) noexcept(see below);
template<class U = T> constexpr optional& operator=(U&&);
template<class U> constexpr optional& operator=(const optional<U>&);
template<class U> constexpr optional& operator=(optional<U>&&);
template<class... Args> constexpr T& emplace(Args&&...);
template<class U, class... Args> constexpr T& emplace(initializer_list<U>, Args&&...);

// 22.5.3.5, swap
constexpr void swap(optional&) noexcept(see below);

// 22.5.3.6, observers
constexpr const T* operator->() const noexcept;
constexpr T* operator->() noexcept;
constexpr const T& operator*() const & noexcept;
constexpr T& operator*() & noexcept;
constexpr T&& operator*() && noexcept;
constexpr const T&& operator*() const && noexcept;
constexpr explicit operator bool() const noexcept;
constexpr bool has_value() const noexcept;
constexpr const T& value() const &;
constexpr T& value() &;
constexpr T&& value() &&;
constexpr const T&& value() const &&;
template<class U> constexpr T value_or(U&&) const &;
template<class U> constexpr T value_or(U&&) &&;

// 22.5.3.7, monadic operations
template<class F> constexpr auto and_then(F&& f) &;
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &;
template<class F> constexpr auto and_then(F&& f) const &&;
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &;
template<class F> constexpr auto transform(F&& f) const &&;
template<class F> constexpr optional or_else(F&& f) &&;
template<class F> constexpr optional or_else(F&& f) const &;

// 22.5.3.8, modifiers
constexpr void reset() noexcept;

```

```
private:
    T *val;           // exposition only
};

template<class T>
    optional(T) -> optional<T>;
}
```

Any instance of `optional<T>` at any given time either contains a value or does not contain a value. When an instance of `optional<T>` *contains a value*, it means that an object of type `T`, referred to as the optional object's *contained value*, is allocated within the storage of the optional object. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate its contained value. When an object of type `optional<T>` is contextually converted to `bool`, the conversion returns `true` if the object contains a value; otherwise the conversion returns `false`.

When an `optional<T>` object contains a value, member `val` points to the contained value.

`T` shall be a type other than `cv in_place_t` or `cv nullopt_t` that meets the *Cpp17Destructible* requirements (Table 35).

22.5.3.2 Constructors

[optional.ctor]

The exposition-only variable template *converts-from-any-cvref* is used by some constructors for `optional`.

```
template<class T, class W>
constexpr bool converts-from-any-cvref = // exposition only
    disjunction_v<is_constructible<T, W&>, is_convertible<W&, T>,
                 is_constructible<T, W>, is_convertible<W, T>,
                 is_constructible<T, const W&>, is_convertible<const W&, T>,
                 is_constructible<T, const W>, is_convertible<const W, T>>;

constexpr optional() noexcept;
constexpr optional(nullopt_t) noexcept;
```

Postconditions: `*this` does not contain a value.

Remarks: No contained value is initialized. For every object type `T` these constructors are constexpr constructors (9.2.6).

```
constexpr optional(const optional& rhs);
```

Effects: If `rhs` contains a value, direct-non-list-initializes the contained value with `*rhs`.

Postconditions: `rhs.has_value() == this->has_value()`.

Throws: Any exception thrown by the selected constructor of `T`.

Remarks: This constructor is defined as deleted unless `is_copy_constructible_v<T>` is `true`. If `is_trivially_copy_constructible_v<T>` is `true`, this constructor is trivial.

```
constexpr optional(optional&& rhs) noexcept(see below);
```

Constraints: `is_move_constructible_v<T>` is `true`.

Effects: If `rhs` contains a value, direct-non-list-initializes the contained value with `std::move(*rhs)`. `rhs.has_value()` is unchanged.

Postconditions: `rhs.has_value() == this->has_value()`.

Throws: Any exception thrown by the selected constructor of `T`.

Remarks: The exception specification is equivalent to `is_nothrow_move_constructible_v<T>`. If `is_trivially_move_constructible_v<T>` is `true`, this constructor is trivial.

```
template<class... Args> constexpr explicit optional(in_place_t, Args&&... args);
```

Constraints: `is_constructible_v<T, Args...>` is `true`.

Effects: Direct-non-list-initializes the contained value with `std::forward<Args>(args)...`

Postconditions: `*this` contains a value.

Throws: Any exception thrown by the selected constructor of `T`.

Remarks: If T's constructor selected for the initialization is a constexpr constructor, this constructor is a constexpr constructor.

```
template<class U, class... Args>
```

```
constexpr explicit optional(in_place_t, initializer_list<U> il, Args&&... args);
```

Constraints: `is_constructible_v<T, initializer_list<U>&, Args...>` is true.

Effects: Direct-non-list-initializes the contained value with `il, std::forward<Args>(args)...`

Postconditions: `*this` contains a value.

Throws: Any exception thrown by the selected constructor of T.

Remarks: If T's constructor selected for the initialization is a constexpr constructor, this constructor is a constexpr constructor.

```
template<class U = T> constexpr explicit(see below) optional(U&& v);
```

Constraints:

- `is_constructible_v<T, U>` is true,
- `is_same_v<remove_cvref_t<U>, in_place_t>` is false,
- `is_same_v<remove_cvref_t<U>, optional>` is false, and
- if T is *cv* bool, `remove_cvref_t<U>` is not a specialization of `optional`.

Effects: Direct-non-list-initializes the contained value with `std::forward<U>(v)`.

Postconditions: `*this` contains a value.

Throws: Any exception thrown by the selected constructor of T.

Remarks: If T's selected constructor is a constexpr constructor, this constructor is a constexpr constructor. The expression inside `explicit` is equivalent to:

```
!is_convertible_v<U, T>
```

```
template<class U> constexpr explicit(see below) optional(const optional<U>& rhs);
```

Constraints:

- `is_constructible_v<T, const U&>` is true, and
- if T is not *cv* bool, `converts-from-any-cvref<T, optional<U>>` is false.

Effects: If `rhs` contains a value, direct-non-list-initializes the contained value with `*rhs`.

Postconditions: `rhs.has_value() == this->has_value()`.

Throws: Any exception thrown by the selected constructor of T.

Remarks: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<const U&, T>
```

```
template<class U> constexpr explicit(see below) optional(optional<U>&& rhs);
```

Constraints:

- `is_constructible_v<T, U>` is true, and
- if T is not *cv* bool, `converts-from-any-cvref<T, optional<U>>` is false.

Effects: If `rhs` contains a value, direct-non-list-initializes the contained value with `std::move(*rhs)`. `rhs.has_value()` is unchanged.

Postconditions: `rhs.has_value() == this->has_value()`.

Throws: Any exception thrown by the selected constructor of T.

Remarks: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<U, T>
```

22.5.3.3 Destructor**[optional.dtor]**

constexpr ~optional();

Effects: If `is_trivially_destructible_v<T> != true` and `*this` contains a value, calls `val->T::~~T()`

Remarks: If `is_trivially_destructible_v<T>` is true, then this destructor is trivial.

22.5.3.4 Assignment**[optional.assign]**

constexpr optional<T>& operator=(nullopt_t) noexcept;

Effects: If `*this` contains a value, calls `val->T::~~T()` to destroy the contained value; otherwise no effect.

Postconditions: `*this` does not contain a value.

Returns: `*this`.

constexpr optional<T>& operator=(const optional& rhs);

Effects: See Table 58.

Table 58 — `optional::operator=(const optional&)` effects [tab:optional.assign.copy]

	*this contains a value	*this does not contain a value
rhs contains a value	assigns <code>*rhs</code> to the contained value	direct-non-list-initializes the contained value with <code>*rhs</code>
rhs does not contain a value	destroys the contained value by calling <code>val->T::~~T()</code>	no effect

Postconditions: `rhs.has_value() == this->has_value()`.

Returns: `*this`.

Remarks: If any exception is thrown, the result of the expression `this->has_value()` remains unchanged. If an exception is thrown during the call to `T`'s copy constructor, no effect. If an exception is thrown during the call to `T`'s copy assignment, the state of its contained value is as defined by the exception safety guarantee of `T`'s copy assignment. This operator is defined as deleted unless `is_copy_constructible_v<T>` is true and `is_copy_assignable_v<T>` is true. If `is_trivially_copy_constructible_v<T> && is_trivially_copy_assignable_v<T> && is_trivially_destructible_v<T>` is true, this assignment operator is trivial.

constexpr optional& operator=(optional&& rhs) noexcept(see below);

Constraints: `is_move_constructible_v<T>` is true and `is_move_assignable_v<T>` is true.

Effects: See Table 59. The result of the expression `rhs.has_value()` remains unchanged.

Table 59 — `optional::operator=(optional&&)` effects [tab:optional.assign.move]

	*this contains a value	*this does not contain a value
rhs contains a value	assigns <code>std::move(*rhs)</code> to the contained value	direct-non-list-initializes the contained value with <code>std::move(*rhs)</code>
rhs does not contain a value	destroys the contained value by calling <code>val->T::~~T()</code>	no effect

Postconditions: `rhs.has_value() == this->has_value()`.

Returns: `*this`.

Remarks: The exception specification is equivalent to:

```
is_nothrow_move_assignable_v<T> && is_nothrow_move_constructible_v<T>
```

If any exception is thrown, the result of the expression `this->has_value()` remains unchanged. If an exception is thrown during the call to `T`'s move constructor, the state of `*rhs.val` is determined by the exception safety guarantee of `T`'s move constructor. If an exception is thrown during the call to `T`'s move assignment, the state of `*val` and `*rhs.val` is determined by the exception safety guarantee of `T`'s move assignment. If `is_trivially_move_constructible_v<T> && is_trivially_move_assignable_v<T> && is_trivially_destructible_v<T>` is true, this assignment operator is trivial.

```
template<class U = T> constexpr optional<T>& operator=(U&& v);
```

Constraints: `is_same_v<remove_cvref_t<U>, optional>` is false, `conjunction_v<is_scalar<T>, is_same<T, decay_t<U>>>` is false, `is_constructible_v<T, U>` is true, and `is_assignable_v<T&, U>` is true.

Effects: If `*this` contains a value, assigns `std::forward<U>(v)` to the contained value; otherwise direct-non-list-initializes the contained value with `std::forward<U>(v)`.

Postconditions: `*this` contains a value.

Returns: `*this`.

Remarks: If any exception is thrown, the result of the expression `this->has_value()` remains unchanged. If an exception is thrown during the call to `T`'s constructor, the state of `v` is determined by the exception safety guarantee of `T`'s constructor. If an exception is thrown during the call to `T`'s assignment, the state of `*val` and `v` is determined by the exception safety guarantee of `T`'s assignment.

```
template<class U> constexpr optional<T>& operator=(const optional<U>& rhs);
```

Constraints:

- `is_constructible_v<T, const U&>` is true,
- `is_assignable_v<T&, const U&>` is true,
- `converts-from-any-cvref<T, optional<U>>` is false,
- `is_assignable_v<T&, optional<U>&>` is false,
- `is_assignable_v<T&, optional<U>&&>` is false,
- `is_assignable_v<T&, const optional<U>&>` is false, and
- `is_assignable_v<T&, const optional<U>&&>` is false.

Effects: See Table 60.

Table 60 — `optional::operator=(const optional<U>&)` effects [tab:optional.assign.copy.templ]

	<code>*this</code> contains a value	<code>*this</code> does not contain a value
<code>rhs</code> contains a value	assigns <code>*rhs</code> to the contained value	direct-non-list-initializes the contained value with <code>*rhs</code>
<code>rhs</code> does not contain a value	destroys the contained value by calling <code>val->T::~~T()</code>	no effect

Postconditions: `rhs.has_value() == this->has_value()`.

Returns: `*this`.

Remarks: If any exception is thrown, the result of the expression `this->has_value()` remains unchanged. If an exception is thrown during the call to `T`'s constructor, the state of `*rhs.val` is determined by the exception safety guarantee of `T`'s constructor. If an exception is thrown during the call to `T`'s assignment, the state of `*val` and `*rhs.val` is determined by the exception safety guarantee of `T`'s assignment.

```
template<class U> constexpr optional<T>& operator=(optional<U>&& rhs);
```

Constraints:

- `is_constructible_v<T, U>` is true,
- `is_assignable_v<T&, U>` is true,
- `converts-from-any-cvref<T, optional<U>>` is false,
- `is_assignable_v<T&, optional<U>&>` is false,
- `is_assignable_v<T&, optional<U>&&>` is false,
- `is_assignable_v<T&, const optional<U>&>` is false, and
- `is_assignable_v<T&, const optional<U>&&>` is false.

Effects: See Table 61. The result of the expression `rhs.has_value()` remains unchanged.

Table 61 — `optional::operator=(optional<U>&&)` effects [tab:optional.assign.move.templ]

	*this contains a value	*this does not contain a value
rhs contains a value	assigns <code>std::move(*rhs)</code> to the contained value	direct-non-list-initializes the contained value with <code>std::move(*rhs)</code>
rhs does not contain a value	destroys the contained value by calling <code>val->T::~~T()</code>	no effect

Postconditions: `rhs.has_value() == this->has_value()`.

Returns: `*this`.

Remarks: If any exception is thrown, the result of the expression `this->has_value()` remains unchanged. If an exception is thrown during the call to `T`'s constructor, the state of `*rhs.val` is determined by the exception safety guarantee of `T`'s constructor. If an exception is thrown during the call to `T`'s assignment, the state of `*val` and `*rhs.val` is determined by the exception safety guarantee of `T`'s assignment.

```
template<class... Args> constexpr T& emplace(Args&&... args);
```

Mandates: `is_constructible_v<T, Args...>` is true.

Effects: Calls `*this = nullopt`. Then direct-non-list-initializes the contained value with `std::forward<Args>(args)...`

Postconditions: `*this` contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of `T`.

Remarks: If an exception is thrown during the call to `T`'s constructor, `*this` does not contain a value, and the previous `*val` (if any) has been destroyed.

```
template<class U, class... Args> constexpr T& emplace(initializer_list<U> il, Args&&... args);
```

Constraints: `is_constructible_v<T, initializer_list<U>&, Args...>` is true.

Effects: Calls `*this = nullopt`. Then direct-non-list-initializes the contained value with `il, std::forward<Args>(args)...`

Postconditions: `*this` contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of `T`.

Remarks: If an exception is thrown during the call to `T`'s constructor, `*this` does not contain a value, and the previous `*val` (if any) has been destroyed.

22.5.3.5 Swap

[optional.swap]

```
constexpr void swap(optional& rhs) noexcept(see below);
```

Mandates: `is_move_constructible_v<T>` is true.

Preconditions: T meets the *Cpp17Swappable* requirements (16.4.4.3).

Effects: See Table 62.

Table 62 — `optional::swap(optional&)` effects [tab:optional.swap]

	*this contains a value	*this does not contain a value
rhs contains a value	calls <code>swap>(*this, rhs)</code>	direct-non-list-initializes the contained value of <code>*this</code> with <code>std::move(rhs)</code> , followed by <code>rhs.val->T::~T()</code> ; postcondition is that <code>*this</code> contains a value and <code>rhs</code> does not contain a value
rhs does not contain a value	direct-non-list-initializes the contained value of <code>rhs</code> with <code>std::move(*this)</code> , followed by <code>val->T::~T()</code> ; postcondition is that <code>*this</code> does not contain a value and <code>rhs</code> contains a value	no effect

Throws: Any exceptions thrown by the operations in the relevant part of Table 62.

Remarks: The exception specification is equivalent to:

```
is_nothrow_move_constructible_v<T> && is_nothrow_swappable_v<T>
```

If any exception is thrown, the results of the expressions `this->has_value()` and `rhs.has_value()` remain unchanged. If an exception is thrown during the call to function `swap`, the state of `*val` and `*rhs.val` is determined by the exception safety guarantee of `swap` for lvalues of T. If an exception is thrown during the call to T's move constructor, the state of `*val` and `*rhs.val` is determined by the exception safety guarantee of T's move constructor.

22.5.3.6 Observers

[optional.observe]

```
constexpr const T* operator->() const noexcept;
constexpr T* operator->() noexcept;
```

Preconditions: `*this` contains a value.

Returns: `val`.

Remarks: These functions are constexpr functions.

```
constexpr const T& operator*() const & noexcept;
constexpr T& operator*() & noexcept;
```

Preconditions: `*this` contains a value.

Returns: `*val`.

Remarks: These functions are constexpr functions.

```
constexpr T&& operator*() && noexcept;
constexpr const T&& operator*() const && noexcept;
```

Preconditions: `*this` contains a value.

Effects: Equivalent to: `return std::move(*val);`

```
constexpr explicit operator bool() const noexcept;
```

Returns: `true` if and only if `*this` contains a value.

Remarks: This function is a constexpr function.

```
constexpr bool has_value() const noexcept;
```

Returns: true if and only if *this contains a value.

Remarks: This function is a constexpr function.

```
constexpr const T& value() const &;
constexpr T& value() &;
```

Effects: Equivalent to:

```
return has_value() ? *val : throw bad_optional_access();
```

```
constexpr T&& value() &&;
constexpr const T&& value() const &&;
```

Effects: Equivalent to:

```
return has_value() ? std::move(*val) : throw bad_optional_access();
```

```
template<class U> constexpr T value_or(U&& v) const &;
```

Mandates: is_copy_constructible_v<T> && is_convertible_v<U&&, T> is true.

Effects: Equivalent to:

```
return has_value() ? **this : static_cast<T>(std::forward<U>(v));
```

```
template<class U> constexpr T value_or(U&& v) &&;
```

Mandates: is_move_constructible_v<T> && is_convertible_v<U&&, T> is true.

Effects: Equivalent to:

```
return has_value() ? std::move(**this) : static_cast<T>(std::forward<U>(v));
```

22.5.3.7 Monadic operations

[optional.monadic]

```
template<class F> constexpr auto and_then(F&& f) &;
template<class F> constexpr auto and_then(F&& f) const &;
```

Let U be invoke_result_t<F, decltype(value())>.

Mandates: remove_cvref_t<U> is a specialization of optional.

Effects: Equivalent to:

```
if (*this) {
    return invoke(std::forward<F>(f), value());
} else {
    return remove_cvref_t<U>();
}
```

```
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &&;
```

Let U be invoke_result_t<F, decltype(std::move(value()))>.

Mandates: remove_cvref_t<U> is a specialization of optional.

Effects: Equivalent to:

```
if (*this) {
    return invoke(std::forward<F>(f), std::move(value()));
} else {
    return remove_cvref_t<U>();
}
```

```
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) const &;
```

Let U be remove_cv_t<invoke_result_t<F, decltype(value())>>.

Mandates: U is a non-array object type other than in_place_t or nullopt_t. The declaration

```
U u(invoke(std::forward<F>(f), value()));
```

is well-formed for some invented variable u.

NOTE 1 There is no requirement that U is movable (9.4.1).

Returns: If `*this` contains a value, an `optional<U>` object whose contained value is direct-non-list-initialized with `invoke(std::forward<F>(f), value())`; otherwise, `optional<U>()`.

```
template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &&;
```

Let U be `remove_cv_t<invoke_result_t<F, decltype(std::move(value()))>>`.

Mandates: U is a non-array object type other than `in_place_t` or `nullopt_t`. The declaration

```
U u(invoke(std::forward<F>(f), std::move(value())));
```

is well-formed for some invented variable u.

NOTE 2 There is no requirement that U is movable (9.4.1).

Returns: If `*this` contains a value, an `optional<U>` object whose contained value is direct-non-list-initialized with `invoke(std::forward<F>(f), std::move(value()))`; otherwise, `optional<U>()`.

```
template<class F> constexpr optional or_else(F&& f) const &;
```

Constraints: F models `invocable<>` and T models `copy_constructible`.

Mandates: `is_same_v<remove_cvref_t<invoke_result_t<F>>, optional>` is true.

Effects: Equivalent to:

```
if (*this) {
    return *this;
} else {
    return std::forward<F>(f)();
}
```

```
template<class F> constexpr optional or_else(F&& f) &&;
```

Constraints: F models `invocable<>` and T models `move_constructible`.

Mandates: `is_same_v<remove_cvref_t<invoke_result_t<F>>, optional>` is true.

Effects: Equivalent to:

```
if (*this) {
    return std::move(*this);
} else {
    return std::forward<F>(f)();
}
```

22.5.3.8 Modifiers

[optional.mod]

```
constexpr void reset() noexcept;
```

Effects: If `*this` contains a value, calls `val->T::~~T()` to destroy the contained value; otherwise no effect.

Postconditions: `*this` does not contain a value.

22.5.4 No-value state indicator

[optional.nullopt]

```
struct nullopt_t{see below};
inline constexpr nullopt_t nullopt(unspecified);
```

The struct `nullopt_t` is an empty class type used as a unique type to indicate the state of not containing a value for `optional` objects. In particular, `optional<T>` has a constructor with `nullopt_t` as a single argument; this indicates that an optional object not containing a value shall be constructed.

Type `nullopt_t` shall not have a default constructor or an initializer-list constructor, and shall not be an aggregate.

22.5.5 Class `bad_optional_access`**[optional.bad.access]**

```

namespace std {
    class bad_optional_access : public exception {
    public:
        // see 17.9.3 for the specification of the special member functions
        const char* what() const noexcept override;
    };
}

```

The class `bad_optional_access` defines the type of objects thrown as exceptions to report the situation where an attempt is made to access the value of an optional object that does not contain a value.

```
const char* what() const noexcept override;
```

Returns: An implementation-defined NTBS.

22.5.6 Relational operators**[optional.relops]**

```
template<class T, class U> constexpr bool operator==(const optional<T>& x, const optional<U>& y);
```

Mandates: The expression `*x == *y` is well-formed and its result is convertible to `bool`.

NOTE `T` need not be *Cpp17EqualityComparable*.

Returns: If `x.has_value() != y.has_value()`, `false`; otherwise if `x.has_value() == false`, `true`; otherwise `*x == *y`.

Remarks: Specializations of this function template for which `*x == *y` is a core constant expression are `constexpr` functions.

```
template<class T, class U> constexpr bool operator!=(const optional<T>& x, const optional<U>& y);
```

Mandates: The expression `*x != *y` is well-formed and its result is convertible to `bool`.

Returns: If `x.has_value() != y.has_value()`, `true`; otherwise, if `x.has_value() == false`, `false`; otherwise `*x != *y`.

Remarks: Specializations of this function template for which `*x != *y` is a core constant expression are `constexpr` functions.

```
template<class T, class U> constexpr bool operator<(const optional<T>& x, const optional<U>& y);
```

Mandates: `*x < *y` is well-formed and its result is convertible to `bool`.

Returns: If `!y`, `false`; otherwise, if `!x`, `true`; otherwise `*x < *y`.

Remarks: Specializations of this function template for which `*x < *y` is a core constant expression are `constexpr` functions.

```
template<class T, class U> constexpr bool operator>(const optional<T>& x, const optional<U>& y);
```

Mandates: The expression `*x > *y` is well-formed and its result is convertible to `bool`.

Returns: If `!x`, `false`; otherwise, if `!y`, `true`; otherwise `*x > *y`.

Remarks: Specializations of this function template for which `*x > *y` is a core constant expression are `constexpr` functions.

```
template<class T, class U> constexpr bool operator<=(const optional<T>& x, const optional<U>& y);
```

Mandates: The expression `*x <= *y` is well-formed and its result is convertible to `bool`.

Returns: If `!x`, `true`; otherwise, if `!y`, `false`; otherwise `*x <= *y`.

Remarks: Specializations of this function template for which `*x <= *y` is a core constant expression are `constexpr` functions.

```
template<class T, class U> constexpr bool operator>=(const optional<T>& x, const optional<U>& y);
```

Mandates: The expression `*x >= *y` is well-formed and its result is convertible to `bool`.

Returns: If `!y`, `true`; otherwise, if `!x`, `false`; otherwise `*x >= *y`.

Remarks: Specializations of this function template for which `*x >= *y` is a core constant expression are `constexpr` functions.

```
template<class T, three_way_comparable_with<T> U>
constexpr compare_three_way_result_t<T, U>
operator<=>(const optional<T>& x, const optional<U>& y);
```

Returns: If $x \ \&\& \ y$, $*x \ \<=> \ *y$; otherwise $x.has\_value() \ \<=> \ y.has\_value()$.

Remarks: Specializations of this function template for which $*x \ \<=> \ *y$ is a core constant expression are constexpr functions.

22.5.7 Comparison with nullopt

[optional.nullopts]

```
template<class T> constexpr bool operator==(const optional<T>& x, nullopt_t) noexcept;
```

Returns: !x.

```
template<class T> constexpr strong_ordering operator<=>(const optional<T>& x, nullopt_t) noexcept;
```

Returns: x.has_value() <=> false.

22.5.8 Comparison with T

[optional.comp.with.t]

```
template<class T, class U> constexpr bool operator==(const optional<T>& x, const U& v);
```

Mandates: The expression $*x == v$ is well-formed and its result is convertible to bool.

NOTE T need not be *Cpp17EqualityComparable*.

Effects: Equivalent to: `return x.has_value() ? *x == v : false;`

```
template<class T, class U> constexpr bool operator==(const T& v, const optional<U>& x);
```

Mandates: The expression $v == *x$ is well-formed and its result is convertible to bool.

Effects: Equivalent to: `return x.has_value() ? v == *x : false;`

```
template<class T, class U> constexpr bool operator!=(const optional<T>& x, const U& v);
```

Mandates: The expression $*x != v$ is well-formed and its result is convertible to bool.

Effects: Equivalent to: `return x.has_value() ? *x != v : true;`

```
template<class T, class U> constexpr bool operator!=(const T& v, const optional<U>& x);
```

Mandates: The expression $v != *x$ is well-formed and its result is convertible to bool.

Effects: Equivalent to: `return x.has_value() ? v != *x : true;`

```
template<class T, class U> constexpr bool operator<(const optional<T>& x, const U& v);
```

Mandates: The expression $*x < v$ is well-formed and its result is convertible to bool.

Effects: Equivalent to: `return x.has_value() ? *x < v : true;`

```
template<class T, class U> constexpr bool operator<(const T& v, const optional<U>& x);
```

Mandates: The expression $v < *x$ is well-formed and its result is convertible to bool.

Effects: Equivalent to: `return x.has_value() ? v < *x : false;`

```
template<class T, class U> constexpr bool operator>(const optional<T>& x, const U& v);
```

Mandates: The expression $*x > v$ is well-formed and its result is convertible to bool.

Effects: Equivalent to: `return x.has_value() ? *x > v : false;`

```
template<class T, class U> constexpr bool operator>(const T& v, const optional<U>& x);
```

Mandates: The expression $v > *x$ is well-formed and its result is convertible to bool.

Effects: Equivalent to: `return x.has_value() ? v > *x : true;`

```
template<class T, class U> constexpr bool operator<=(const optional<T>& x, const U& v);
```

Mandates: The expression $*x <= v$ is well-formed and its result is convertible to bool.

Effects: Equivalent to: `return x.has_value() ? *x <= v : true;`

```
template<class T, class U> constexpr bool operator<=(const T& v, const optional<U>& x);
```

Mandates: The expression `v <= *x` is well-formed and its result is convertible to `bool`.

Effects: Equivalent to: `return x.has_value() ? v <= *x : false;`

```
template<class T, class U> constexpr bool operator>=(const optional<T>& x, const U& v);
```

Mandates: The expression `*x >= v` is well-formed and its result is convertible to `bool`.

Effects: Equivalent to: `return x.has_value() ? *x >= v : false;`

```
template<class T, class U> constexpr bool operator>=(const T& v, const optional<U>& x);
```

Mandates: The expression `v >= *x` is well-formed and its result is convertible to `bool`.

Effects: Equivalent to: `return x.has_value() ? v >= *x : true;`

```
template<class T, class U>
    requires (!is-derived-from-optional<U>) && three_way_comparable_with<T, U>
constexpr compare_three_way_result_t<T, U>
    operator<=>(const optional<T>& x, const U& v);
```

Effects: Equivalent to: `return x.has_value() ? *x <=> v : strong_ordering::less;`

22.5.9 Specialized algorithms

[optional.specalg]

```
template<class T>
    constexpr void swap(optional<T>& x, optional<T>& y) noexcept(noexcept(x.swap(y)));
```

Constraints: `is_move_constructible_v<T>` is true and `is_swappable_v<T>` is true.

Effects: Calls `x.swap(y)`.

```
template<class T> constexpr optional<decay_t<T>> make_optional(T&& v);
```

Returns: `optional<decay_t<T>>(std::forward<T>(v))`.

```
template<class T, class... Args>
    constexpr optional<T> make_optional(Args&&... args);
```

Effects: Equivalent to: `return optional<T>(in_place, std::forward<Args>(args)...);`

```
template<class T, class U, class... Args>
    constexpr optional<T> make_optional(initializer_list<U> il, Args&&... args);
```

Effects: Equivalent to: `return optional<T>(in_place, il, std::forward<Args>(args)...);`

22.5.10 Hash support

[optional.hash]

```
template<class T> struct hash<optional<T>>;
```

The specialization `hash<optional<T>>` is enabled (22.10.19) if and only if `hash<remove_const_t<T>>` is enabled. When enabled, for an object `o` of type `optional<T>`, if `o.has_value() == true`, then `hash<optional<T>>()(o)` evaluates to the same value as `hash<remove_const_t<T>>()(*o)`; otherwise it evaluates to an unspecified value. The member functions are not guaranteed to be `noexcept`.

22.6 Variants

[variant]

22.6.1 General

[variant.general]

A variant object holds and manages the lifetime of a value. If the `variant` holds a value, that value's type has to be one of the template argument types given to `variant`. These template arguments are called alternatives.

22.6.2 Header <variant> synopsis

[variant.syn]

```
#include <compare> // see 17.11.1

namespace std {
    // 22.6.3, class template variant
    template<class... Types>
        class variant;
```

```

// 22.6.4, variant helper classes
template<class T> struct variant_size; // not defined
template<class T> struct variant_size<const T>;
template<class T>
    constexpr size_t variant_size_v = variant_size<T>::value;

template<class... Types>
    struct variant_size<variant<Types...>>;

template<size_t I, class T> struct variant_alternative; // not defined
template<size_t I, class T> struct variant_alternative<I, const T>;
template<size_t I, class T>
    using variant_alternative_t = typename variant_alternative<I, T>::type;

template<size_t I, class... Types>
    struct variant_alternative<I, variant<Types...>>;

inline constexpr size_t variant_npos = -1;

// 22.6.5, value access
template<class T, class... Types>
    constexpr bool holds_alternative(const variant<Types...>&) noexcept;

template<size_t I, class... Types>
    constexpr variant_alternative_t<I, variant<Types...>&> get(variant<Types...>&);
template<size_t I, class... Types>

template<class T> struct hash;
template<class... Types> struct hash<variant<Types...>>;
template<> struct hash<monostate>;
}

```

22.6.3 Class template variant

[variant.variant]

22.6.3.1 General

[variant.variant.general]

```

namespace std {
    template<class... Types>
    class variant {
    public:
        // 22.6.3.2, constructors
        constexpr variant() noexcept(see below);
        constexpr variant(const variant&);
        constexpr variant(variant&&) noexcept(see below);

        template<class T>
            constexpr variant(T&&) noexcept(see below);

        template<class T, class... Args>
            constexpr explicit variant(in_place_type_t<T>, Args&&...);
        template<class T, class U, class... Args>
            constexpr explicit variant(in_place_type_t<T>, initializer_list<U>, Args&&...);

        template<size_t I, class... Args>
            constexpr explicit variant(in_place_index_t<I>, Args&&...);
        template<size_t I, class U, class... Args>
            constexpr explicit variant(in_place_index_t<I>, initializer_list<U>, Args&&...);

        // 22.6.3.3, destructor
        constexpr ~variant();

        // 22.6.3.4, assignment
        constexpr variant& operator=(const variant&);
    };
}

```

```

constexpr variant& operator=(variant&&) noexcept(see below);

template<class T> constexpr variant& operator=(T&&) noexcept(see below);

// 22.6.3.5, modifiers
template<class T, class... Args>
    constexpr T& emplace(Args&&...);
template<class T, class U, class... Args>
    constexpr T& emplace(initializer_list<U>, Args&&...);
template<size_t I, class... Args>
    constexpr variant_alternative_t<I, variant<Types...>>& emplace(Args&&...);
template<size_t I, class U, class... Args>
    constexpr variant_alternative_t<I, variant<Types...>>&
        emplace(initializer_list<U>, Args&&...);

// 22.6.3.6, value status
constexpr bool valueless_by_exception() const noexcept;
constexpr size_t index() const noexcept;

// 22.6.3.7, swap
constexpr void swap(variant&) noexcept(see below);
};
}

```

Any instance of **variant** at any given time either holds a value of one of its alternative types or holds no value. When an instance of **variant** holds a value of alternative type **T**, it means that a value of type **T**, referred to as the **variant** object's *contained value*, is allocated within the storage of the **variant** object. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate the contained value.

All types in **Types** shall meet the *Cpp17Destructible* requirements (Table 35).

A program that instantiates the definition of **variant** with no template arguments is ill-formed.

22.6.3.2 Constructors [variant.ctor]

In the descriptions that follow, let i be in the range $[0, \text{sizeof} \dots (\text{Types}))$, and T_i be the i^{th} type in **Types**.

```
constexpr variant() noexcept(see below);
```

Constraints: `is_default_constructible_v<T0>` is true.

Effects: Constructs a **variant** holding a value-initialized value of type T_0 .

Postconditions: `valueless_by_exception()` is false and `index()` is 0.

Throws: Any exception thrown by the value-initialization of T_0 .

Remarks: This function is `constexpr` if and only if the value-initialization of the alternative type T_0 would be `constexpr-suitable` (9.2.6). The exception specification is equivalent to `is_nothrow_default_constructible_v<T0>`.

NOTE 1 See also class `monostate`.

```
constexpr variant(const variant& w);
```

Effects: If **w** holds a value, initializes the **variant** to hold the same alternative as **w** and direct-initializes the contained value with `get<j>(w)`, where j is `w.index()`. Otherwise, initializes the **variant** to not hold a value.

Throws: Any exception thrown by direct-initializing any T_i for all i .

Remarks: This constructor is defined as deleted unless `is_copy_constructible_v<Ti>` is true for all i . If `is_trivially_copy_constructible_v<Ti>` is true for all i , this constructor is trivial.

```
constexpr variant(variant&& w) noexcept(see below);
```

Constraints: `is_move_constructible_v<Ti>` is true for all i .

Effects: If **w** holds a value, initializes the **variant** to hold the same alternative as **w** and direct-initializes the contained value with `get<j>(std::move(w))`, where j is `w.index()`. Otherwise, initializes the **variant** to not hold a value.

Throws: Any exception thrown by move-constructing any T_i for all i .

Remarks: The exception specification is equivalent to the logical AND of `is_nothrow_move_constructible_v< $T_i$ >` for all i . If `is_trivially_move_constructible_v< $T_i$ >` is true for all i , this constructor is trivial.

```
template<class T> constexpr variant(T&& t) noexcept(see below);
```

Let T_j be a type that is determined as follows: build an imaginary function $FUN(T_i)$ for each alternative type T_i for which $T_i \ x[] = \{\text{std::forward}<T>(t)\}$; is well-formed for some invented variable x . The overload $FUN(T_j)$ selected by overload resolution for the expression $FUN(\text{std::forward}<T>(t))$ defines the alternative T_j which is the type of the contained value after construction.

Constraints:

- `sizeof...(Types)` is nonzero,
- `is_same_v<remove_cvref_t<T>, variant>` is false,
- `remove_cvref_t<T>` is neither a specialization of `in_place_type_t` nor a specialization of `in_place_index_t`,
- `is_constructible_v< $T_j$ , T>` is true, and
- the expression $FUN(\text{std::forward}<T>(t))$ (with FUN being the above-mentioned set of imaginary functions) is well-formed.

NOTE 2

```
variant<string, string> v("abc");
```

is ill-formed, as both alternative types have an equally viable constructor for the argument.

Effects: Initializes `*this` to hold the alternative type T_j and direct-non-list-initializes the contained value with `std::forward<T>(t)`.

Postconditions: `holds_alternative< $T_j$ >(*this)` is true.

Throws: Any exception thrown by the initialization of the selected alternative T_j .

Remarks: The exception specification is equivalent to `is_nothrow_constructible_v< $T_j$ , T>`. If T_j 's selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

```
template<class T, class... Args> constexpr explicit variant(in_place_type_t<T>, Args&&... args);
```

Constraints:

- There is exactly one occurrence of T in `Types...` and
- `is_constructible_v<T, Args...>` is true.

Effects: Direct-non-list-initializes the contained value of type T with `std::forward<Args>(args)...`

Postconditions: `holds_alternative<T>(*this)` is true.

Throws: Any exception thrown by calling the selected constructor of T .

Remarks: If T 's selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

```
template<class T, class U, class... Args>
constexpr explicit variant(in_place_type_t<T>, initializer_list<U> il, Args&&... args);
```

Constraints:

- There is exactly one occurrence of T in `Types...` and
- `is_constructible_v<T, initializer_list<U>&, Args...>` is true.

Effects: Direct-non-list-initializes the contained value of type T with `il, std::forward<Args>(args)...`

Postconditions: `holds_alternative<T>(*this)` is true.

Throws: Any exception thrown by calling the selected constructor of T .

Remarks: If T 's selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

```
template<size_t I, class... Args> constexpr explicit variant(in_place_index_t<I>, Args&&... args);
```

Constraints:

- I is less than sizeof...(Types) and
- is_constructible_v<T_I, Args...> is true.

Effects: Direct-non-list-initializes the contained value of type T_I with std::forward<Args>(args)....

Postconditions: index() is I.

Throws: Any exception thrown by calling the selected constructor of T_I.

Remarks: If T_I's selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

```
template<size_t I, class U, class... Args>
```

```
constexpr explicit variant(in_place_index_t<I>, initializer_list<U> il, Args&&... args);
```

Constraints:

- I is less than sizeof...(Types) and
- is_constructible_v<T_I, initializer_list<U>&, Args...> is true.

Effects: Direct-non-list-initializes the contained value of type T_I with il, std::forward<Args>(args)....

Postconditions: index() is I.

Remarks: If T_I's selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

22.6.3.3 Destructor

[variant.dtor]

```
constexpr ~variant();
```

Effects: If valueless_by_exception() is false, destroys the currently contained value.

Remarks: If is_trivially_destructible_v<T_i> is true for all T_i, then this destructor is trivial.

22.6.3.4 Assignment

[variant.assign]

```
constexpr variant& operator=(const variant& rhs);
```

Let *j* be rhs.index().

Effects:

- If neither *this nor rhs holds a value, there is no effect.
- Otherwise, if *this holds a value but rhs does not, destroys the value contained in *this and sets *this to not hold a value.
- Otherwise, if index() == *j*, assigns the value contained in rhs to the value contained in *this.
- Otherwise, if either is_nothrow_copy_constructible_v<T_j> is true or is_nothrow_move_constructible_v<T_j> is false, equivalent to emplace<*j*>(get<*j*>(rhs)).
- Otherwise, equivalent to operator=(variant(rhs)).

Postconditions: index() == rhs.index().

Returns: *this.

Remarks: This operator is defined as deleted unless is_copy_constructible_v<T_i> && is_copy_assignable_v<T_i> is true for all *i*. If is_trivially_copy_constructible_v<T_i> && is_trivially_copy_assignable_v<T_i> && is_trivially_destructible_v<T_i> is true for all *i*, this assignment operator is trivial.

```
constexpr variant& operator=(variant&& rhs) noexcept(see below);
```

Let *j* be rhs.index().

Constraints: is_move_constructible_v<T_i> && is_move_assignable_v<T_i> is true for all *i*.

Effects:

- If neither `*this` nor `rhs` holds a value, there is no effect.
- Otherwise, if `*this` holds a value but `rhs` does not, destroys the value contained in `*this` and sets `*this` to not hold a value.
- Otherwise, if `index() == j`, assigns `get<j>(std::move(rhs))` to the value contained in `*this`.
- Otherwise, equivalent to `emplace<j>(get<j>(std::move(rhs)))`.

Returns: `*this`.

Remarks: If `is_trivially_move_constructible_v<Ti> && is_trivially_move_assignable_v<Ti> && is_trivially_destructible_v<Ti>` is true for all i , this assignment operator is trivial. The exception specification is equivalent to `is_nothrow_move_constructible_v<Ti> && is_nothrow_move_assignable_v<Ti>` for all i .

- If an exception is thrown during the call to T_j 's move construction (with j being `rhs.index()`), the `variant` will hold no value.
- If an exception is thrown during the call to T_j 's move assignment, the state of the contained value is as defined by the exception safety guarantee of T_j 's move assignment; `index()` will be j .

```
template<class T> constexpr variant& operator=(T&& t) noexcept(see below);
```

Let T_j be a type that is determined as follows: build an imaginary function $FUN(T_i)$ for each alternative type T_i for which $T_i \ x[] = \{\text{std::forward}<T>(t)\}$; is well-formed for some invented variable x . The overload $FUN(T_j)$ selected by overload resolution for the expression $FUN(\text{std::forward}<T>(t))$ defines the alternative T_j which is the type of the contained value after assignment.

Constraints:

- `is_same_v<remove_cvref_t<T>, variant>` is false,
- `is_assignable_v<Tj&, T> && is_constructible_v<Tj, T>` is true, and
- the expression $FUN(\text{std::forward}<T>(t))$ (with FUN being the above-mentioned set of imaginary functions) is well-formed.

NOTE

```
variant<string, string> v;  
v = "abc";
```

is ill-formed, as both alternative types have an equally viable constructor for the argument.

Effects:

- If `*this` holds a T_j , assigns `std::forward<T>(t)` to the value contained in `*this`.
- Otherwise, if `is_nothrow_constructible_v<Tj, T> || !is_nothrow_move_constructible_v<Tj>` is true, equivalent to `emplace<j>(std::forward<T>(t))`.
- Otherwise, equivalent to `emplace<j>(Tj(std::forward<T>(t)))`.

Postconditions: `holds_alternative<Tj is true, with  $T_j$  selected by the imaginary function overload resolution described above.`

Returns: `*this`.

Remarks: The exception specification is equivalent to:

```
is_nothrow_assignable_v<Tj&, T> && is_nothrow_constructible_v<Tj, T>
```

- If an exception is thrown during the assignment of `std::forward<T>(t)` to the value contained in `*this`, the state of the contained value and `t` are as defined by the exception safety guarantee of the assignment expression; `valueless_by_exception()` will be false.
- If an exception is thrown during the initialization of the contained value, the `variant` object is permitted to not hold a value.

22.6.3.5 Modifiers

[variant.mod]

```
template<class T, class... Args> constexpr T& emplace(Args&&... args);
```

Constraints: `is_constructible_v<T, Args...>` is true, and T occurs exactly once in `Types`.

Effects: Equivalent to:

```
return emplace<I>(std::forward<Args>(args)...);
```

where *I* is the zero-based index of *T* in *Types*.

```
template<class T, class U, class... Args>
```

```
constexpr T& emplace(initializer_list<U> il, Args&&... args);
```

Constraints: `is_constructible_v<T, initializer_list<U>&, Args...>` is true, and *T* occurs exactly once in *Types*.

Effects: Equivalent to:

```
return emplace<I>(il, std::forward<Args>(args)...);
```

where *I* is the zero-based index of *T* in *Types*.

```
template<size_t I, class... Args>
```

```
constexpr variant_alternative_t<I, variant<Types...>&& emplace(Args&&... args);
```

Mandates: `I < sizeof...(Types)`.

Constraints: `is_constructible_v<TI, Args...>` is true.

Effects: Destroys the currently contained value if `valueless_by_exception()` is false. Then direct-non-list-initializes the contained value of type *T_I* with the arguments `std::forward<Args>(args)...`.

Postconditions: `index()` is *I*.

Returns: A reference to the new contained value.

Throws: Any exception thrown during the initialization of the contained value.

Remarks: If an exception is thrown during the initialization of the contained value, the `variant` is permitted to not hold a value.

```
template<size_t I, class U, class... Args>
```

```
constexpr variant_alternative_t<I, variant<Types...>&& emplace(initializer_list<U> il, Args&&... args);
```

Mandates: `I < sizeof...(Types)`.

Constraints: `is_constructible_v<TI, initializer_list<U>&, Args...>` is true.

Effects: Destroys the currently contained value if `valueless_by_exception()` is false. Then direct-non-list-initializes the contained value of type *T_I* with *il*, `std::forward<Args>(args)...`.

Postconditions: `index()` is *I*.

Returns: A reference to the new contained value.

Throws: Any exception thrown during the initialization of the contained value.

Remarks: If an exception is thrown during the initialization of the contained value, the `variant` is permitted to not hold a value.

22.6.3.6 Value status

[variant.status]

```
constexpr bool valueless_by_exception() const noexcept;
```

Effects: Returns false if and only if the `variant` holds a value.

NOTE It is possible for a `variant` to hold no value if an exception is thrown during a type-changing assignment or emplacement. The latter means that even a `variant<float, int>` can become `valueless_by_exception()`, for instance by

```
struct S { operator int() { throw 42; } };
variant<float, int> v{12.f};
v.emplace<1>(S());
```

```
constexpr size_t index() const noexcept;
```

Effects: If `valueless_by_exception()` is true, returns `variant_npos`. Otherwise, returns the zero-based index of the alternative of the contained value.

22.6.3.7 Swap**[variant.swap]**

```
constexpr void swap(variant& rhs) noexcept(see below);
```

Mandates: `is_move_constructible_v<Ti>` is true for all *i*.

Preconditions: Each *T_i* meets the *Cpp17Swappable* requirements (16.4.4.3).

Effects:

- If `valueless_by_exception()` && `rhs.valueless_by_exception()` no effect.
- Otherwise, if `index() == rhs.index()`, calls `swap(get<i>(*this), get<i>(rhs))` where *i* is `index()`.
- Otherwise, exchanges values of `rhs` and `*this`.

Throws: If `index() == rhs.index()`, any exception thrown by `swap(get<i>(*this), get<i>(rhs))` with *i* being `index()`. Otherwise, any exception thrown by the move constructor of *T_i* or *T_j* with *i* being `index()` and *j* being `rhs.index()`.

Remarks: If an exception is thrown during the call to function `swap(get<i>(*this), get<i>(rhs))`, the states of the contained values of `*this` and of `rhs` are determined by the exception safety guarantee of `swap` for lvalues of *T_i* with *i* being `index()`. If an exception is thrown during the exchange of the values of `*this` and `rhs`, the states of the values of `*this` and of `rhs` are determined by the exception safety guarantee of `variant`'s move constructor. The exception specification is equivalent to the logical AND of `is_nothrow_move_constructible_v<Ti>` && `is_nothrow_swappable_v<Ti>` for all *i*.

22.6.4 variant helper classes**[variant.helper]**

```
template<class T> struct variant_size;
```

All specializations of `variant_size` meet the *Cpp17UnaryTypeTrait* requirements (21.3.2) with a base characteristic of `integral_constant<size_t, N>` for some *N*.

```
template<class T> struct variant_size<const T>;
```

Let *VS* denote `variant_size<T>` of the cv-unqualified type *T*. Then each specialization of the template meets the *Cpp17UnaryTypeTrait* requirements (21.3.2) with a base characteristic of `integral_constant<size_t, VS::value>`.

```
template<class... Types>
struct variant_size<variant<Types...>> : integral_constant<size_t, sizeof...(Types)> { };
```

```
template<size_t I, class T> struct variant_alternative<I, const T>;
```

Let *VA* denote `variant_alternative<I, T>` of the cv-unqualified type *T*. Then each specialization of the template meets the *Cpp17TransformationTrait* requirements (21.3.2) with a member typedef `type` that names the type `add_const_t<VA::type>`.

```
variant_alternative<I, variant<Types...>>::type
```

Mandates: `I < sizeof...(Types)`.

Type: The type *T_I*.

22.6.5 Value access**[variant.get]**

```
template<class T, class... Types>
constexpr bool holds_alternative(const variant<Types...>& v) noexcept;
```

Mandates: The type *T* occurs exactly once in *Types*.

Returns: true if `index()` is equal to the zero-based index of *T* in *Types*.

```
template<size_t I, class... Types>
constexpr variant_alternative_t<I, variant<Types...>>& get(variant<Types...>& v);
template<size_t I, class... Types>
constexpr variant_alternative_t<I, variant<Types...>>&& get(const variant<Types...>&& v);
template<size_t I, class... Types>
constexpr const variant_alternative_t<I, variant<Types...>>& get(const variant<Types...>& v);
```

```
template<size_t I, class... Types>
constexpr const variant_alternative_t<I, variant<Types...>&& get(const variant<Types...>&& v);
```

Mandates: $I < \text{sizeof} \dots (\text{Types})$.

Effects: If $v.\text{index}()$ is I , returns a reference to the object stored in the `variant`. Otherwise, throws an exception of type `bad_variant_access`.

```
template<class T, class... Types> constexpr T& get(variant<Types...>& v);
template<class T, class... Types> constexpr T&& get(variant<Types...>&& v);
template<class T, class... Types> constexpr const T& get(const variant<Types...>& v);
template<class T, class... Types> constexpr const T&& get(const variant<Types...>&& v);
```

Mandates: The type T occurs exactly once in Types .

Effects: If v holds a value of type T , returns a reference to that value. Otherwise, throws an exception of type `bad_variant_access`.

```
template<size_t I, class... Types>
constexpr add_pointer_t<variant_alternative_t<I, variant<Types...>>>
get_if(variant<Types...>* v) noexcept;
```

```
template<size_t I, class... Types>
constexpr add_pointer_t<const variant_alternative_t<I, variant<Types...>>>
get_if(const variant<Types...>* v) noexcept;
```

Mandates: $I < \text{sizeof} \dots (\text{Types})$.

Returns: A pointer to the value stored in the `variant`, if $v \neq \text{nullptr}$ and $v \rightarrow \text{index}() == I$. Otherwise, returns `nullptr`.

```
template<class T, class... Types>
constexpr add_pointer_t<T>
get_if(variant<Types...>* v) noexcept;
template<class T, class... Types>
constexpr add_pointer_t<const T>
get_if(const variant<Types...>* v) noexcept;
```

Mandates: The type T occurs exactly once in Types .

Effects: Equivalent to: `return get_if<i>(v);` with i being the zero-based index of T in Types .

22.6.6 Relational operators

[variant.relops]

```
template<class... Types>
constexpr bool operator==(const variant<Types...>& v, const variant<Types...>& w);
```

Mandates: `get<i>(v) == get<i>(w)` is a valid expression that is convertible to `bool`, for all i .

Returns: If $v.\text{index}() \neq w.\text{index}()$, `false`; otherwise if $v.\text{valueless\_by\_exception}()$, `true`; otherwise `get<i>(v) == get<i>(w)` with i being $v.\text{index}()$.

```
template<class... Types>
constexpr bool operator!=(const variant<Types...>& v, const variant<Types...>& w);
```

Mandates: `get<i>(v) != get<i>(w)` is a valid expression that is convertible to `bool`, for all i .

Returns: If $v.\text{index}() \neq w.\text{index}()$, `true`; otherwise if $v.\text{valueless\_by\_exception}()$, `false`; otherwise `get<i>(v) != get<i>(w)` with i being $v.\text{index}()$.

```
template<class... Types>
constexpr bool operator<(const variant<Types...>& v, const variant<Types...>& w);
```

Mandates: `get<i>(v) < get<i>(w)` is a valid expression that is convertible to `bool`, for all i .

Returns: If $w.\text{valueless\_by\_exception}()$, `false`; otherwise if $v.\text{valueless\_by\_exception}()$, `true`; otherwise, if $v.\text{index}() < w.\text{index}()$, `true`; otherwise if $v.\text{index}() > w.\text{index}()$, `false`; otherwise `get<i>(v) < get<i>(w)` with i being $v.\text{index}()$.

```
template<class... Types>
constexpr bool operator>(const variant<Types...>& v, const variant<Types...>& w);
```

Mandates: `get<i>(v) > get<i>(w)` is a valid expression that is convertible to `bool`, for all i .

Returns: If `v.valueless_by_exception()`, false; otherwise if `w.valueless_by_exception()`, true; otherwise, if `v.index() > w.index()`, true; otherwise if `v.index() < w.index()`, false; otherwise `get< i >(v) > get< i >(w)` with *i* being `v.index()`.

```
template<class... Types>
```

```
constexpr bool operator<=(const variant<Types...>& v, const variant<Types...>& w);
```

Mandates: `get< i >(v) <= get< i >(w)` is a valid expression that is convertible to bool, for all *i*.

Returns: If `v.valueless_by_exception()`, true; otherwise if `w.valueless_by_exception()`, false; otherwise, if `v.index() < w.index()`, true; otherwise if `v.index() > w.index()`, false; otherwise `get< i >(v) <= get< i >(w)` with *i* being `v.index()`.

```
template<class... Types>
```

```
constexpr bool operator>=(const variant<Types...>& v, const variant<Types...>& w);
```

Mandates: `get< i >(v) >= get< i >(w)` is a valid expression that is convertible to bool, for all *i*.

Returns: If `w.valueless_by_exception()`, true; otherwise if `v.valueless_by_exception()`, false; otherwise, if `v.index() > w.index()`, true; otherwise if `v.index() < w.index()`, false; otherwise `get< i >(v) >= get< i >(w)` with *i* being `v.index()`.

```
template<class... Types> requires (three_way_comparable<Types> && ...)
```

```
constexpr common_comparison_category_t<compare_three_way_result_t<Types>...>
```

```
operator<=>(const variant<Types...>& v, const variant<Types...>& w);
```

Effects: Equivalent to:

```
if (v.valueless_by_exception() && w.valueless_by_exception())
    return strong_ordering::equal;
if (v.valueless_by_exception()) return strong_ordering::less;
if (w.valueless_by_exception()) return strong_ordering::greater;
if (auto c = v.index() <=> w.index(); c != 0) return c;
return get< i >(v) <=> get< i >(w);
```

with *i* being `v.index()`.

22.6.7 Visitation

[variant.visit]

```
template<class Visitor, class... Variants>
```

```
constexpr see below visit(Visitor&& vis, Variants&&... vars);
```

```
template<class R, class Visitor, class... Variants>
```

```
constexpr R visit(Visitor&& vis, Variants&&... vars);
```

Let *as-variant* denote the following exposition-only function templates:

```
template<class... Ts>
    auto&& as-variant(variant<Ts...>& var) { return var; }
template<class... Ts>
    auto&& as-variant(const variant<Ts...>& var) { return var; }
template<class... Ts>
    auto&& as-variant(variant<Ts...>&& var) { return std::move(var); }
template<class... Ts>
    auto&& as-variant(const variant<Ts...>&& var) { return std::move(var); }
```

Let *n* be `sizeof...(Variants)`. For each $0 \leq i < n$, let V_i denote the type `decltype(as-variant(std::forward<Variantsi>(varsi)))`.

Constraints: V_i is a valid type for all $0 \leq i < n$.

Let *V* denote the pack of types V_i .

Let *m* be a pack of *n* values of type `size_t`. Such a pack is valid if

$0 \leq m_i < \text{variant\_size\_v}<\text{remove\_reference\_t}<V_i>>$ for all $0 \leq i < n$. For each valid pack *m*, let *e(m)* denote the expression:

```
INVOKE(std::forward<Visitor>(vis), get< m >(std::forward<V>(vars))...) // see 22.10.4
```

for the first form and

```
INVOKE<R>(std::forward<Visitor>(vis), get< m >(std::forward<V>(vars))...) // see 22.10.4
```

for the second form.

Mandates: For each valid pack m , $e(m)$ is a valid expression. All such expressions are of the same type and value category.

Returns: $e(m)$, where m is the pack for which m_i is `as-variant(varsi).index()` for all $0 \leq i < n$. The return type is `decltype(e(m))` for the first form.

Throws: `bad_variant_access` if `(as-variant(vars).valueless_by_exception() || ...)` is true.

Complexity: For $n \leq 1$, the invocation of the callable object is implemented in constant time, i.e., for $n = 1$, it does not depend on the number of alternative types of V_0 . For $n > 1$, the invocation of the callable object has no complexity requirements.

22.6.8 Class `monostate`

[variant.monostate]

```
struct monostate{};
```

The class `monostate` can serve as a first alternative type for a `variant` to make the `variant` type default constructible.

22.6.9 `monostate` relational operators

[variant.monostate.relops]

```
constexpr bool operator==(monostate, monostate) noexcept { return true; }
constexpr strong_ordering operator<=>(monostate, monostate) noexcept
{ return strong_ordering::equal; }
```

NOTE `monostate` objects have only a single state; they thus always compare equal.

22.6.10 Specialized algorithms

[variant.specalg]

```
template<class... Types>
constexpr void swap(variant<Types...& v, variant<Types...& w) noexcept (see below);
```

Constraints: `is_move_constructible_v<Ti>` && `is_swappable_v<Ti>` is true for all i .

Effects: Equivalent to `v.swap(w)`.

Remarks: The exception specification is equivalent to `noexcept(v.swap(w))`.

22.6.11 Class `bad_variant_access`

[variant.bad.access]

```
namespace std {
    class bad_variant_access : public exception {
    public:
        // see 17.9.3 for the specification of the special member functions
        const char* what() const noexcept override;
    };
}
```

Objects of type `bad_variant_access` are thrown to report invalid accesses to the value of a `variant` object.

```
const char* what() const noexcept override;
```

Returns: An implementation-defined NTBS.

22.6.12 Hash support

[variant.hash]

```
template<class... Types> struct hash<variant<Types...>>;
```

The specialization `hash<variant<Types...>>` is enabled (22.10.19) if and only if every specialization in `hash<remove_const_t<Types>>...` is enabled. The member functions are not guaranteed to be `noexcept`.

```
template<> struct hash<monostate>;
```

The specialization is enabled (22.10.19).

22.7 Storage for any type

[any]

22.7.1 General

[any.general]

Subclause 22.7 describes components that C++ programs may use to perform operations on objects of a discriminated type.

NOTE The discriminated type can contain values of different types but does not attempt conversion between them, i.e., 5 is held strictly as an `int` and is not implicitly convertible either to "5" or to 5.0. This indifference to interpretation but awareness of type effectively allows safe, generic containers of single values, with no scope for surprises from ambiguous conversions.

22.7.2 Header `<any>` synopsis

[any.synop]

```
namespace std {
    // 22.7.3, class bad_any_cast
    class bad_any_cast;

    // 22.7.4, class any
    class any;

    // 22.7.5, non-member functions
    void swap(any& x, any& y) noexcept;

    template<class T, class... Args>
        any make_any(Args&&... args);
    template<class T, class U, class... Args>
        any make_any(initializer_list<U> il, Args&&... args);

    template<class T>
        T any_cast(const any& operand);
    template<class T>
        T any_cast(any& operand);
    template<class T>
        T any_cast(any&& operand);

    template<class T>
        const T* any_cast(const any* operand) noexcept;
    template<class T>
        T* any_cast(any* operand) noexcept;
}
```

22.7.3 Class `bad_any_cast`

[any.bad.any.cast]

```
namespace std {
    class bad_any_cast : public bad_cast {
    public:
        // see 17.9.3 for the specification of the special member functions
        const char* what() const noexcept override;
    };
}
```

Objects of type `bad_any_cast` are thrown by a failed `any_cast` (22.7.5).

```
const char* what() const noexcept override;
```

Returns: An implementation-defined NTBS.

22.7.4 Class `any`

[any.class]

22.7.4.1 General

[any.class.general]

```
namespace std {
    class any {
    public:
        // 22.7.4.2, construction and destruction
        constexpr any() noexcept;

        any(const any& other);
        any(any&& other) noexcept;

        template<class T>
            any(T&& value);
```

```

template<class T, class... Args>
    explicit any(in_place_type_t<T>, Args&&...);
template<class T, class U, class... Args>
    explicit any(in_place_type_t<T>, initializer_list<U>, Args&&...);

~any();

// 22.7.4.3, assignments
any& operator=(const any& rhs);
any& operator=(any&& rhs) noexcept;

template<class T>
    any& operator=(T&& rhs);

// 22.7.4.4, modifiers
template<class T, class... Args>
    decay_t<T>& emplace(Args&&...);
template<class T, class U, class... Args>
    decay_t<T>& emplace(initializer_list<U>, Args&&...);
void reset() noexcept;
void swap(any& rhs) noexcept;

// 22.7.4.5, observers
bool has_value() const noexcept;
const type_info& type() const noexcept;
};
}

```

An object of class **any** stores an instance of any type that meets the constructor requirements or it has no value, and this is referred to as the *state* of the class **any** object. The stored instance is called the *contained value*. Two states are equivalent if either they both have no value, or they both have a value and the contained values are equivalent.

The non-member **any_cast** functions provide type-safe access to the contained value.

Implementations should avoid the use of dynamically allocated memory for a small contained value. However, any such small-object optimization shall only be applied to types **T** for which **is_nothrow_move_constructible_v<T>** is true.

EXAMPLE A contained value of type **int** can be stored in an internal buffer, not in separately-allocated memory.

22.7.4.2 Construction and destruction

[**any.cons**]

```
constexpr any() noexcept;
```

Postconditions: **has_value()** is false.

```
any(const any& other);
```

Effects: If **other.has_value()** is false, constructs an object that has no value. Otherwise, equivalent to **any(in_place_type<T>, any_cast<const T&>(other))** where **T** is the type of the contained value.

Throws: Any exceptions arising from calling the selected constructor for the contained value.

```
any(any&& other) noexcept;
```

Effects: If **other.has_value()** is false, constructs an object that has no value. Otherwise, constructs an object of type **any** that contains either the contained value of **other**, or contains an object of the same type constructed from the contained value of **other** considering that contained value as an rvalue.

```
template<class T>
    any(T&& value);
```

Let **VT** be **decay_t<T>**.

Constraints: **VT** is not the same type as **any**, **VT** is not a specialization of **in_place_type_t**, and **is_copy_constructible_v<VT>** is true.

Preconditions: **VT** meets the *Cpp17CopyConstructible* requirements.

Effects: Constructs an object of type **any** that contains an object of type VT direct-initialized with `std::forward<T>(value)`.

Throws: Any exception thrown by the selected constructor of VT.

```
template<class T, class... Args>
explicit any(in_place_type_t<T>, Args&&... args);
```

Let VT be `decay_t<T>`.

Constraints: `is_copy_constructible_v<VT>` is true and `is_constructible_v<VT, Args...>` is true.

Preconditions: VT meets the *Cpp17CopyConstructible* requirements.

Effects: Direct-non-list-initializes the contained value of type VT with `std::forward<Args>(args)...`

Postconditions: `*this` contains a value of type VT.

Throws: Any exception thrown by the selected constructor of VT.

```
template<class T, class U, class... Args>
explicit any(in_place_type_t<T>, initializer_list<U> il, Args&&... args);
```

Let VT be `decay_t<T>`.

Constraints: `is_copy_constructible_v<VT>` is true and `is_constructible_v<VT, initializer_list<U>&, Args...>` is true.

Preconditions: VT meets the *Cpp17CopyConstructible* requirements.

Effects: Direct-non-list-initializes the contained value of type VT with `il, std::forward<Args>(args)...`

Postconditions: `*this` contains a value.

Throws: Any exception thrown by the selected constructor of VT.

```
~any();
```

Effects: As if by `reset()`.

22.7.4.3 Assignment

[any.assign]

```
any& operator=(const any& rhs);
```

Effects: As if by `any(rhs).swap(*this)`. No effects if an exception is thrown.

Returns: `*this`.

Throws: Any exceptions arising from the copy constructor for the contained value.

```
any& operator=(any&& rhs) noexcept;
```

Effects: As if by `any(std::move(rhs)).swap(*this)`.

Postconditions: The state of `*this` is equivalent to the original state of `rhs`.

Returns: `*this`.

```
template<class T>
any& operator=(T&& rhs);
```

Let VT be `decay_t<T>`.

Constraints: VT is not the same type as **any** and `is_copy_constructible_v<VT>` is true.

Preconditions: VT meets the *Cpp17CopyConstructible* requirements.

Effects: Constructs an object `tmp` of type **any** that contains an object of type VT direct-initialized with `std::forward<T>(rhs)`, and `tmp.swap(*this)`. No effects if an exception is thrown.

Returns: `*this`.

Throws: Any exception thrown by the selected constructor of VT.

22.7.4.4 Modifiers

[any.modifiers]

```
template<class T, class... Args>
decay_t<T>& emplace(Args&&... args);
```

Let VT be decay_t<T>.

Constraints: is_copy_constructible_v<VT> is true and is_constructible_v<VT, Args...> is true.

Preconditions: VT meets the *Cpp17CopyConstructible* requirements.

Effects: Calls reset(). Then direct-non-list-initializes the contained value of type VT with std::forward<Args>(args)....

Postconditions: *this contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of VT.

Remarks: If an exception is thrown during the call to VT's constructor, *this does not contain a value, and any previously contained value has been destroyed.

```
template<class T, class U, class... Args>
decay_t<T>& emplace(initializer_list<U> il, Args&&... args);
```

Let VT be decay_t<T>.

Constraints: is_copy_constructible_v<VT> is true and is_constructible_v<VT, initializer_list<U>&, Args...> is true.

Preconditions: VT meets the *Cpp17CopyConstructible* requirements.

Effects: Calls reset(). Then direct-non-list-initializes the contained value of type VT with il, std::forward<Args>(args)....

Postconditions: *this contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of VT.

Remarks: If an exception is thrown during the call to VT's constructor, *this does not contain a value, and any previously contained value has been destroyed.

```
void reset() noexcept;
```

Effects: If has_value() is true, destroys the contained value.

Postconditions: has_value() is false.

```
void swap(any& rhs) noexcept;
```

Effects: Exchanges the states of *this and rhs.

22.7.4.5 Observers

[any.observers]

```
bool has_value() const noexcept;
```

Returns: true if *this contains an object, otherwise false.

```
const type_info& type() const noexcept;
```

Returns: typeid(T) if *this has a contained value of type T, otherwise typeid(void).

NOTE Useful for querying against types known either at compile time or only at runtime.

22.7.5 Non-member functions

[any.nonmembers]

```
void swap(any& x, any& y) noexcept;
```

Effects: Equivalent to x.swap(y).

```
template<class T, class... Args>
any make_any(Args&&... args);
```

Effects: Equivalent to: return any(in_place_type<T>, std::forward<Args>(args)...);

```
template<class T, class U, class... Args>
    any make_any(initializer_list<U> il, Args&&... args);
```

Effects: Equivalent to: `return any(in_place_type<T>, il, std::forward<Args>(args)...);`

```
template<class T>
    T any_cast(const any& operand);
template<class T>
    T any_cast(any& operand);
template<class T>
    T any_cast(any&& operand);
```

Let U be the type `remove_cvref_t<T>`.

Mandates: For the first overload, `is_constructible_v<T, const U&>` is true. For the second overload, `is_constructible_v<T, U&>` is true. For the third overload, `is_constructible_v<T, U>` is true.

Returns: For the first and second overload, `static_cast<T>(*any_cast<U>(&operand))`. For the third overload, `static_cast<T>(std::move(*any_cast<U>(&operand)))`.

Throws: `bad_any_cast` if `operand.type() != typeid(remove_reference_t<T>)`.

EXAMPLE 1

```
any x(5); // x holds int
assert(any_cast<int>(x) == 5); // cast to value
any_cast<int&>(x) = 10; // cast to reference
assert(any_cast<int>(x) == 10);

x = "Meow"; // x holds const char*
assert(strcmp(any_cast<const char*>(x), "Meow") == 0);
any_cast<const char*&>(x) = "Harry";
assert(strcmp(any_cast<const char*>(x), "Harry") == 0);

x = string("Meow"); // x holds string
string s, s2("Jane");
s = move(any_cast<string&>(x)); // move from any
assert(s == "Meow");
any_cast<string&>(x) = move(s2); // move to any
assert(any_cast<const string&>(x) == "Jane");

string cat("Meow");
const any y(cat); // const y holds string
assert(any_cast<const string&>(y) == cat);

any_cast<string&>(y); // error: cannot any_cast away const
```

```
template<class T>
    const T* any_cast(const any* operand) noexcept;
template<class T>
    T* any_cast(any* operand) noexcept;
```

Returns: If `operand != nullptr` && `operand->type() == typeid(T)`, a pointer to the object contained by `operand`; otherwise, `nullptr`.

EXAMPLE 2

```
bool is_string(const any& operand) {
    return any_cast<string>(&operand) != nullptr;
}
```

22.8 Expected objects

[expected]

22.8.1 General

[expected.general]

Subclause 22.8 describes the class template `expected` that represents expected objects. An `expected<T, E>` object holds an object of type `T` or an object of type `unexpected<E>` and manages the lifetime of the contained objects.

22.8.2 Header <expected> synopsis

[expected.syn]

```

namespace std {
    // 22.8.3, class template unexpected
    template<class E> class unexpected;

    // 22.8.4, class template bad_expected_access
    template<class E> class bad_expected_access;

    // 22.8.5, specialization for void
    template<> class bad_expected_access<void>;

    // in-place construction of unexpected values
    struct unexpect_t {
        explicit unexpect_t() = default;
    };
    inline constexpr unexpect_t unexpect{};

    // 22.8.6, class template expected
    template<class T, class E> class expected;

    // 22.8.7, partial specialization of expected for void types
    template<class T, class E> requires is_void_v<T> class expected<T, E>;
}

```

22.8.3 Class template unexpected

[expected.unexpected]

22.8.3.1 General

[expected.un.general]

Subclause 22.8.3 describes the class template `unexpected` that represents unexpected objects stored in expected objects.

```

namespace std {
    template<class E>
    class unexpected {
    public:
        // 22.8.3.2, constructors
        constexpr unexpected(const unexpected&) = default;
        constexpr unexpected(unexpected&&) = default;
        template<class Err = E>
            constexpr explicit unexpected(Err&&);
        template<class... Args>
            constexpr explicit unexpected(in_place_t, Args&&...);
        template<class U, class... Args>
            constexpr explicit unexpected(in_place_t, initializer_list<U>, Args&&...);

        constexpr unexpected& operator=(const unexpected&) = default;
        constexpr unexpected& operator=(unexpected&&) = default;

        constexpr const E& error() const & noexcept;
        constexpr E& error() & noexcept;
        constexpr const E&& error() const && noexcept;
        constexpr E&& error() && noexcept;

        constexpr void swap(unexpected& other) noexcept(see below);

        template<class E2>
            friend constexpr bool operator==(const unexpected&, const unexpected<E2>&);

        friend constexpr void swap(unexpected& x, unexpected& y) noexcept(noexcept(x.swap(y)));

    private:
        E unex; // exposition only
    };
}

```

```
template<class E> unexpected(E) -> unexpected<E>;
}
```

A program that instantiates the definition of `unexpected` for a non-object type, an array type, a specialization of `unexpected`, or a cv-qualified type is ill-formed.

22.8.3.2 Constructors

[expected.un.cons]

```
template<class Err = E>
constexpr explicit unexpected(Err&& e);
```

Constraints:

- `is_same_v<remove_cvref_t<Err>, unexpected>` is false; and
- `is_same_v<remove_cvref_t<Err>, in_place_t>` is false; and
- `is_constructible_v<E, Err>` is true.

Effects: Direct-non-list-initializes `unex` with `std::forward<Err>(e)`.

Throws: Any exception thrown by the initialization of `unex`.

```
template<class... Args>
constexpr explicit unexpected(in_place_t, Args&&... args);
```

Constraints: `is_constructible_v<E, Args...>` is true.

Effects: Direct-non-list-initializes `unex` with `std::forward<Args>(args)...`

Throws: Any exception thrown by the initialization of `unex`.

```
template<class U, class... Args>
constexpr explicit unexpected(in_place_t, initializer_list<U> il, Args&&... args);
```

Constraints: `is_constructible_v<E, initializer_list<U>&, Args...>` is true.

Effects: Direct-non-list-initializes `unex` with `il, std::forward<Args>(args)...`

Throws: Any exception thrown by the initialization of `unex`.

22.8.3.3 Observers

[expected.un.obs]

```
constexpr const E& error() const & noexcept;
constexpr E& error() & noexcept;
```

Returns: `unex`.

```
constexpr E&& error() && noexcept;
constexpr const E&& error() const && noexcept;
```

Returns: `std::move(unex)`.

22.8.3.4 Swap

[expected.un.swap]

```
constexpr void swap(unexpected& other) noexcept(is_nothrow_swappable_v<E>);
```

Mandates: `is_swappable_v<E>` is true.

Effects: Equivalent to: `using std::swap; swap(unex, other.unex);`

```
friend constexpr void swap(unexpected& x, unexpected& y) noexcept(noexcept(x.swap(y)));
```

Constraints: `is_swappable_v<E>` is true.

Effects: Equivalent to `x.swap(y)`.

22.8.3.5 Equality operator

[expected.un.eq]

```
template<class E2>
friend constexpr bool operator==(const unexpected& x, const unexpected<E2>& y);
```

Mandates: The expression `x.error() == y.error()` is well-formed and its result is convertible to `bool`.

Returns: `x.error() == y.error()`.

22.8.4 Class template `bad_expected_access`**[`expected.bad`]**

```

namespace std {
    template<class E>
    class bad_expected_access : public bad_expected_access<void> {
    public:
        explicit bad_expected_access(E);
        const char* what() const noexcept override;
        E& error() & noexcept;
        const E& error() const & noexcept;
        E&& error() && noexcept;
        const E&& error() const && noexcept;

    private:
        E unex;           // exposition only
    };
}

```

The class template `bad_expected_access` defines the type of objects thrown as exceptions to report the situation where an attempt is made to access the value of an `expected<T, E>` object for which `has_value()` is false.

```
explicit bad_expected_access(E e);
```

Effects: Initializes *unex* with `std::move(e)`.

```
const E& error() const & noexcept;
E& error() & noexcept;
```

Returns: *unex*.

```
E&& error() && noexcept;
const E&& error() const && noexcept;
```

Returns: `std::move(unex)`.

```
const char* what() const noexcept override;
```

Returns: An implementation-defined NTBS.

22.8.5 Class template specialization `bad_expected_access<void>` [`expected.bad.void`]

```

namespace std {
    template<>
    class bad_expected_access<void> : public exception {
    protected:
        bad_expected_access() noexcept;
        bad_expected_access(const bad_expected_access&);
        bad_expected_access(bad_expected_access&&);
        bad_expected_access& operator=(const bad_expected_access&);
        bad_expected_access& operator=(bad_expected_access&&);
        ~bad_expected_access();

    public:
        const char* what() const noexcept override;
    };
}

```

```
const char* what() const noexcept override;
```

Returns: An implementation-defined NTBS.

22.8.6 Class template `expected`**[`expected.expected`]****22.8.6.1 General****[`expected.object.general`]**

```

namespace std {
    template<class T, class E>
    class expected {
    public:
        using value_type = T;

```

```

using error_type = E;
using unexpected_type = unexpected<E>;

template<class U>
using rebind = expected<U, error_type>;

// 22.8.6.2, constructors
constexpr expected();
constexpr expected(const expected&);
constexpr expected(expected&&) noexcept(see below);
template<class U, class G>
    constexpr explicit(see below) expected(const expected<U, G>&);
template<class U, class G>
    constexpr explicit(see below) expected(expected<U, G>&&);

template<class U = T>
    constexpr explicit(see below) expected(U&& v);

template<class G>
    constexpr explicit(see below) expected(const unexpected<G>&);
template<class G>
    constexpr explicit(see below) expected(unexpected<G>&&);

template<class... Args>
    constexpr explicit expected(in_place_t, Args&&...);
template<class U, class... Args>
    constexpr explicit expected(in_place_t, initializer_list<U>, Args&&...);
template<class... Args>
    constexpr explicit expected(unexpect_t, Args&&...);
template<class U, class... Args>
    constexpr explicit expected(unexpect_t, initializer_list<U>, Args&&...);

// 22.8.6.3, destructor
constexpr ~expected();

// 22.8.6.4, assignment
constexpr expected& operator=(const expected&);
constexpr expected& operator=(expected&&) noexcept(see below);
template<class U = T> constexpr expected& operator=(U&&);
template<class G>
    constexpr expected& operator=(const unexpected<G>&);
template<class G>
    constexpr expected& operator=(unexpected<G>&&);

template<class... Args>
    constexpr T& emplace(Args&&...) noexcept;
template<class U, class... Args>
    constexpr T& emplace(initializer_list<U>, Args&&...) noexcept;

// 22.8.6.5, swap
constexpr void swap(expected&) noexcept(see below);
friend constexpr void swap(expected& x, expected& y) noexcept(noexcept(x.swap(y)));

// 22.8.6.6, observers
constexpr const T* operator->() const noexcept;
constexpr T* operator->() noexcept;
constexpr const T& operator*() const & noexcept;
constexpr T& operator*() & noexcept;
constexpr const T&& operator*() const && noexcept;
constexpr T&& operator*() && noexcept;
constexpr explicit operator bool() const noexcept;
constexpr bool has_value() const noexcept;
constexpr const T& value() const &;
constexpr T& value() &;

```

```

constexpr const T&& value() const &&;
constexpr T&& value() &&;
constexpr const E& error() const & noexcept;
constexpr E& error() & noexcept;
constexpr const E&& error() const && noexcept;
constexpr E&& error() && noexcept;
template<class U> constexpr T value_or(U&&) const &;
template<class U> constexpr T value_or(U&&) &&;
template<class G = E> constexpr E error_or(G&&) const &;
template<class G = E> constexpr E error_or(G&&) &&;

// 22.8.6.7, monadic operations
template<class F> constexpr auto and_then(F&& f) &;
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &;
template<class F> constexpr auto and_then(F&& f) const &&;
template<class F> constexpr auto or_else(F&& f) &;
template<class F> constexpr auto or_else(F&& f) &&;
template<class F> constexpr auto or_else(F&& f) const &;
template<class F> constexpr auto or_else(F&& f) const &&;
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &;
template<class F> constexpr auto transform(F&& f) const &&;
template<class F> constexpr auto transform_error(F&& f) &;
template<class F> constexpr auto transform_error(F&& f) &&;
template<class F> constexpr auto transform_error(F&& f) const &;
template<class F> constexpr auto transform_error(F&& f) const &&;

// 22.8.6.8, equality operators
template<class T2, class E2> requires (!is_void_v<T2>)
    friend constexpr bool operator==(const expected& x, const expected<T2, E2>& y);
template<class T2>
    friend constexpr bool operator==(const expected&, const T2&);
template<class E2>
    friend constexpr bool operator==(const expected&, const unexpected<E2>&);

private:
    bool has_val;           // exposition only
    union {
        T val;              // exposition only
        E unex;             // exposition only
    };
};
}

```

Any object of type `expected<T, E>` either contains a value of type `T` or a value of type `E` within its own storage. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate the object of type `T` or the object of type `E`. Member `has_val` indicates whether the `expected<T, E>` object contains an object of type `T`.

A type `T` is a *valid value type for `expected`*, if `remove_cv_t<T>` is `void` or a complete non-array object type that is not `in_place_t`, `unexpected_t`, or a specialization of `unexpected`. A program which instantiates class template `expected<T, E>` with an argument `T` that is not a valid value type for `expected` is ill-formed. A program that instantiates the definition of the template `expected<T, E>` with a type for the `E` parameter that is not a valid template argument for `unexpected` is ill-formed.

When `T` is not `cv void`, it shall meet the *Cpp17Destructible* requirements (Table 35). `E` shall meet the *Cpp17Destructible* requirements.

22.8.6.2 Constructors

[`expected.object.cons`]

The exposition-only variable template *converts-from-any-cvref* defined in 22.5.3.2 is used by some constructors for `expected`.

```
constexpr expected();
```

Constraints: `is_default_constructible_v<T>` is true.

Effects: Value-initializes *val*.

Postconditions: `has_value()` is true.

Throws: Any exception thrown by the initialization of *val*.

```
constexpr expected(const expected& rhs);
```

Effects: If `rhs.has_value()` is true, direct-non-list-initializes *val* with **rhs*. Otherwise, direct-non-list-initializes *unex* with `rhs.error()`.

Postconditions: `rhs.has_value() == this->has_value()`.

Throws: Any exception thrown by the initialization of *val* or *unex*.

Remarks: This constructor is defined as deleted unless

- `is_copy_constructible_v<T>` is true and
- `is_copy_constructible_v<E>` is true.

This constructor is trivial if

- `is_trivially_copy_constructible_v<T>` is true and
- `is_trivially_copy_constructible_v<E>` is true.

```
constexpr expected(expected&& rhs) noexcept(see below);
```

Constraints:

- `is_move_constructible_v<T>` is true and
- `is_move_constructible_v<E>` is true.

Effects: If `rhs.has_value()` is true, direct-non-list-initializes *val* with `std::move(*rhs)`. Otherwise, direct-non-list-initializes *unex* with `std::move(rhs.error())`.

Postconditions: `rhs.has_value()` is unchanged; `rhs.has_value() == this->has_value()` is true.

Throws: Any exception thrown by the initialization of *val* or *unex*.

Remarks: The exception specification is equivalent to `is_nothrow_move_constructible_v<T> && is_nothrow_move_constructible_v<E>`.

This constructor is trivial if

- `is_trivially_move_constructible_v<T>` is true and
- `is_trivially_move_constructible_v<E>` is true.

```
template<class U, class G>
```

```
constexpr explicit(see below) expected(const expected<U, G>& rhs);
```

```
template<class U, class G>
```

```
constexpr explicit(see below) expected(expected<U, G>&& rhs);
```

Let:

- *UF* be `const U&` for the first overload and *U* for the second overload.
- *GF* be `const G&` for the first overload and *G* for the second overload.

Constraints:

- `is_constructible_v<T, UF>` is true; and
- `is_constructible_v<E, GF>` is true; and
- if *T* is not *cv* bool, *converts-from-any-cvref*<*T*, `expected<U, G>`> is false; and
- `is_constructible_v<unexpected<E>, expected<U, G>&>` is false; and
- `is_constructible_v<unexpected<E>, expected<U, G>>` is false; and
- `is_constructible_v<unexpected<E>, const expected<U, G>&>` is false; and
- `is_constructible_v<unexpected<E>, const expected<U, G>>` is false.

Effects: If `rhs.has_value()`, direct-non-list-initializes `val` with `std::forward<UF>(*rhs)`. Otherwise, direct-non-list-initializes `unex` with `std::forward<GF>(rhs.error())`.

Postconditions: `rhs.has_value()` is unchanged; `rhs.has_value() == this->has_value()` is true.

Throws: Any exception thrown by the initialization of `val` or `unex`.

Remarks: The expression inside `explicit` is equivalent to `!is_convertible_v<UF, T> || !is_convertible_v<GF, E>`.

```
template<class U = T>
constexpr explicit(!is_convertible_v<U, T>) expected(U&& v);
```

Constraints:

- `is_same_v<remove_cvref_t<U>, in_place_t>` is false; and
- `is_same_v<expected, remove_cvref_t<U>>` is false; and
- `remove_cvref_t<U>` is not a specialization of `unexpected`; and
- `is_constructible_v<T, U>` is true; and
- if `T` is `cv bool`, `remove_cvref_t<U>` is not a specialization of `expected`.

Effects: Direct-non-list-initializes `val` with `std::forward<U>(v)`.

Postconditions: `has_value()` is true.

Throws: Any exception thrown by the initialization of `val`.

```
template<class G>
constexpr explicit(!is_convertible_v<const G&, E>) expected(const unexpected<G>&& e);
template<class G>
constexpr explicit(!is_convertible_v<G, E>) expected(unexpected<G>&& e);
```

Let `GF` be `const G&` for the first overload and `G` for the second overload.

Constraints: `is_constructible_v<E, GF>` is true.

Effects: Direct-non-list-initializes `unex` with `std::forward<GF>(e.error())`.

Postconditions: `has_value()` is false.

Throws: Any exception thrown by the initialization of `unex`.

```
template<class... Args>
constexpr explicit expected(in_place_t, Args&&... args);
```

Constraints: `is_constructible_v<T, Args...>` is true.

Effects: Direct-non-list-initializes `val` with `std::forward<Args>(args)...`

Postconditions: `has_value()` is true.

Throws: Any exception thrown by the initialization of `val`.

```
template<class U, class... Args>
constexpr explicit expected(in_place_t, initializer_list<U> il, Args&&... args);
```

Constraints: `is_constructible_v<T, initializer_list<U>&, Args...>` is true.

Effects: Direct-non-list-initializes `val` with `il, std::forward<Args>(args)...`

Postconditions: `has_value()` is true.

Throws: Any exception thrown by the initialization of `val`.

```
template<class... Args>
constexpr explicit expected(unexpect_t, Args&&... args);
```

Constraints: `is_constructible_v<E, Args...>` is true.

Effects: Direct-non-list-initializes `unex` with `std::forward<Args>(args)...`

Postconditions: `has_value()` is false.

Throws: Any exception thrown by the initialization of `unex`.

```
template<class U, class... Args>
```

```
constexpr explicit expected(unexpect_t, initializer_list<U> il, Args&&... args);
```

Constraints: `is_constructible_v<E, initializer_list<U>&, Args...>` is true.

Effects: Direct-non-list-initializes `unex` with `il`, `std::forward<Args>(args)...`

Postconditions: `has_value()` is false.

Throws: Any exception thrown by the initialization of `unex`.

22.8.6.3 Destructor

[expected.object.dtor]

```
constexpr ~expected();
```

Effects: If `has_value()` is true, destroys `val`, otherwise destroys `unex`.

Remarks: If `is_trivially_destructible_v<T>` is true, and `is_trivially_destructible_v<E>` is true, then this destructor is a trivial destructor.

22.8.6.4 Assignment

[expected.object.assign]

This subclause makes use of the following exposition-only function:

```
template<class T, class U, class... Args>
constexpr void reinit-expected(T& newval, U& oldval, Args&&... args) { Exposition only
    if constexpr (is_nothrow_constructible_v<T, Args...>) {
        destroy_at(addressof(oldval));
        construct_at(addressof(newval), std::forward<Args>(args)...);
    } else if constexpr (is_nothrow_move_constructible_v<T>) {
        T tmp(std::forward<Args>(args)...);
        destroy_at(addressof(oldval));
        construct_at(addressof(newval), std::move(tmp));
    } else {
        U tmp(std::move(oldval));
        destroy_at(addressof(oldval));
        try {
            construct_at(addressof(newval), std::forward<Args>(args)...);
        } catch (...) {
            construct_at(addressof(oldval), std::move(tmp));
            throw;
        }
    }
}
```

```
constexpr expected& operator=(const expected& rhs);
```

Effects:

— If `this->has_value() && rhs.has_value()` is true, equivalent to `val = *rhs`.

— Otherwise, if `this->has_value()` is true, equivalent to:

```
reinit-expected(unex, val, rhs.error())
```

— Otherwise, if `rhs.has_value()` is true, equivalent to:

```
reinit-expected(val, unex, *rhs)
```

— Otherwise, equivalent to `unex = rhs.error()`.

Then, if no exception was thrown, equivalent to: `has_val = rhs.has_value(); return *this;`

Returns: `*this`.

Remarks: This operator is defined as deleted unless:

- `is_copy_assignable_v<T>` is true and
- `is_copy_constructible_v<T>` is true and
- `is_copy_assignable_v<E>` is true and
- `is_copy_constructible_v<E>` is true and
- `is_nothrow_move_constructible_v<T> || is_nothrow_move_constructible_v<E>` is true.

```
constexpr expected& operator=(expected&& rhs) noexcept(see below);
```

Constraints:

- `is_move_constructible_v<T>` is true and
- `is_move_assignable_v<T>` is true and
- `is_move_constructible_v<E>` is true and
- `is_move_assignable_v<E>` is true and
- `is_nothrow_move_constructible_v<T> || is_nothrow_move_constructible_v<E>` is true.

Effects:

- If `this->has_value()` && `rhs.has_value()` is true, equivalent to `val = std::move(*rhs)`.
- Otherwise, if `this->has_value()` is true, equivalent to:
`reinit-expected(unex, val, std::move(rhs.error()))`
- Otherwise, if `rhs.has_value()` is true, equivalent to:
`reinit-expected(val, unex, std::move(*rhs))`
- Otherwise, equivalent to `unex = std::move(rhs.error())`.

Then, if no exception was thrown, equivalent to: `has_val = rhs.has_value(); return *this;`

Returns: `*this`.

Remarks: The exception specification is equivalent to:

```
is_nothrow_move_assignable_v<T> && is_nothrow_move_constructible_v<T> &&  
is_nothrow_move_assignable_v<E> && is_nothrow_move_constructible_v<E>
```

```
template<class U = T>  
constexpr expected& operator=(U&& v);
```

Constraints:

- `is_same_v<expected, remove_cvref_t<U>>` is false; and
- `remove_cvref_t<U>` is not a specialization of `unexpected`; and
- `is_constructible_v<T, U>` is true; and
- `is_assignable_v<T&, U>` is true; and
- `is_nothrow_constructible_v<T, U> || is_nothrow_move_constructible_v<T> || is_nothrow_move_constructible_v<E>` is true.

Effects:

- If `has_value()` is true, equivalent to: `val = std::forward<U>(v);`
- Otherwise, equivalent to:
`reinit-expected(val, unex, std::forward<U>(v));`
`has_val = true;`

Returns: `*this`.

```
template<class G>  
constexpr expected& operator=(const unexpected<G>& e);  
template<class G>  
constexpr expected& operator=(unexpected<G>&& e);
```

Let `GF` be `const G&` for the first overload and `G` for the second overload.

Constraints:

- `is_constructible_v<E, GF>` is true; and
- `is_assignable_v<E&, GF>` is true; and
- `is_nothrow_constructible_v<E, GF> || is_nothrow_move_constructible_v<T> || is_nothrow_move_constructible_v<E>` is true.

Effects:

- If `has_value()` is true, equivalent to:

```
reinit-expected(unex, val, std::forward<GF>(e.error()));
has_val = false;
```
- Otherwise, equivalent to: `unex = std::forward<GF>(e.error());`

Returns: `*this`.

```
template<class... Args>
constexpr T& emplace(Args&&... args) noexcept;

Constraints: is_nothrow_constructible_v<T, Args...> is true.
Effects: Equivalent to:
    if (has_value()) {
        destroy_at(addressof(val));
    } else {
        destroy_at(addressof(unex));
        has_val = true;
    }
    return *construct_at(addressof(val), std::forward<Args>(args)...);
```

```
template<class U, class... Args>
constexpr T& emplace(initializer_list<U> il, Args&&... args) noexcept;

Constraints: is_nothrow_constructible_v<T, initializer_list<U>&, Args...> is true.
Effects: Equivalent to:
    if (has_value()) {
        destroy_at(addressof(val));
    } else {
        destroy_at(addressof(unex));
        has_val = true;
    }
    return *construct_at(addressof(val), il, std::forward<Args>(args)...);
```

22.8.6.5 Swap

[expected.object.swap]

```
constexpr void swap(expected& rhs) noexcept (see below);
```

Constraints:

- `is_swappable_v<T>` is true and
- `is_swappable_v<E>` is true and
- `is_move_constructible_v<T> && is_move_constructible_v<E>` is true, and
- `is_nothrow_move_constructible_v<T> || is_nothrow_move_constructible_v<E>` is true.

Effects: See Table 63.

Table 63 — `swap(expected&)` effects [tab:expected.object.swap]

	<code>this->has_value()</code>	<code>!this->has_value()</code>
<code>rhs.has_value()</code>	equivalent to: using <code>std::swap</code> ; <code>swap(val, rhs.val);</code>	calls <code>rhs.swap(*this)</code>
<code>!rhs.has_value()</code>	see below	equivalent to: using <code>std::swap</code> ; <code>swap(unex, rhs.unex);</code>

For the case where `rhs.value()` is false and `this->has_value()` is true, equivalent to:

```
if constexpr (is_nothrow_move_constructible_v<E>) {
    E tmp(std::move(rhs.unex));
    destroy_at(addressof(rhs.unex));
    try {
        construct_at(addressof(rhs.val), std::move(val));
        destroy_at(addressof(val));
    }
```

```

        construct_at(addressof(unex), std::move(tmp));
    } catch (...) {
        construct_at(addressof(rhs.unex), std::move(tmp));
        throw;
    }
} else {
    T tmp(std::move(val));
    destroy_at(addressof(val));
    try {
        construct_at(addressof(unex), std::move(rhs.unex));
        destroy_at(addressof(rhs.unex));
        construct_at(addressof(rhs.val), std::move(tmp));
    } catch (...) {
        construct_at(addressof(val), std::move(tmp));
        throw;
    }
}
}
has_val = false;
rhs.has_val = true;

```

Throws: Any exception thrown by the expressions in the *Effects*.

Remarks: The exception specification is equivalent to:

```

is_nothrow_move_constructible_v<T> && is_nothrow_swappable_v<T> &&
is_nothrow_move_constructible_v<E> && is_nothrow_swappable_v<E>

```

```
friend constexpr void swap(expected& x, expected& y) noexcept(noexcept(x.swap(y)));
```

Effects: Equivalent to *x.swap(y)*.

22.8.6.6 Observers

[*expected.object.obs*]

```
constexpr const T* operator->() const noexcept;
constexpr T* operator->() noexcept;
```

Preconditions: *has_value()* is true.

Returns: *addressof(val)*.

```
constexpr const T& operator*() const & noexcept;
constexpr T& operator*() & noexcept;
```

Preconditions: *has_value()* is true.

Returns: *val*.

```
constexpr T&& operator*() && noexcept;
constexpr const T&& operator*() const && noexcept;
```

Preconditions: *has_value()* is true.

Returns: *std::move(val)*.

```
constexpr explicit operator bool() const noexcept;
constexpr bool has_value() const noexcept;
```

Returns: *has_val*.

```
constexpr const T& value() const &;
constexpr T& value() &;
```

Mandates: *is_copy_constructible_v<E>* is true.

Returns: *val*, if *has_value()* is true.

Throws: *bad_expected_access(as_const(error()))* if *has_value()* is false.

```
constexpr T&& value() &&;
constexpr const T&& value() const &&;
```

Mandates: *is_copy_constructible_v<E>* is true and *is_constructible_v<E, decltype(std::move(error()))>* is true.

Returns: `std::move(val)`, if `has_value()` is true.

Throws: `bad_expected_access(std::move(error()))` if `has_value()` is false.

```
constexpr const E& error() const & noexcept;
constexpr E& error() & noexcept;
```

Preconditions: `has_value()` is false.

Returns: `unex`.

```
constexpr E&& error() && noexcept;
constexpr const E&& error() const && noexcept;
```

Preconditions: `has_value()` is false.

Returns: `std::move(unex)`.

```
template<class U> constexpr T value_or(U&& v) const &;
```

Mandates: `is_copy_constructible_v<T>` is true and `is_convertible_v<U, T>` is true.

Returns: `has_value()` ? `**this` : `static_cast<T>(std::forward<U>(v))`.

```
template<class U> constexpr T value_or(U&& v) &&;
```

Mandates: `is_move_constructible_v<T>` is true and `is_convertible_v<U, T>` is true.

Returns: `has_value()` ? `std::move(**this)` : `static_cast<T>(std::forward<U>(v))`.

```
template<class G = E> constexpr E error_or(G&& e) const &;
```

Mandates: `is_copy_constructible_v<E>` is true and `is_convertible_v<G, E>` is true.

Returns: `std::forward<G>(e)` if `has_value()` is true, `error()` otherwise.

```
template<class G = E> constexpr E error_or(G&& e) &&;
```

Mandates: `is_move_constructible_v<E>` is true and `is_convertible_v<G, E>` is true.

Returns: `std::forward<G>(e)` if `has_value()` is true, `std::move(error())` otherwise.

22.8.6.7 Monadic operations

[expected.object.monadic]

```
template<class F> constexpr auto and_then(F&& f) &;
template<class F> constexpr auto and_then(F&& f) const &;
```

Let `U` be `remove_cvref_t<invoke_result_t<F, decltype(value())>>`.

Constraints: `is_constructible_v<E, decltype(error())>` is true.

Mandates: `U` is a specialization of `expected` and `is_same_v<U::error_type, E>` is true.

Effects: Equivalent to:

```
if (has_value())
    return invoke(std::forward<F>(f), value());
else
    return U(unexpect, error());
```

```
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &&;
```

Let `U` be `remove_cvref_t<invoke_result_t<F, decltype(std::move(value()))>>`.

Constraints: `is_constructible_v<E, decltype(std::move(error()))>` is true.

Mandates: `U` is a specialization of `expected` and `is_same_v<U::error_type, E>` is true.

Effects: Equivalent to:

```
if (has_value())
    return invoke(std::forward<F>(f), std::move(value()));
else
    return U(unexpect, std::move(error()));
```

```
template<class F> constexpr auto or_else(F&& f) &;
template<class F> constexpr auto or_else(F&& f) const &;
```

Let *G* be `remove_cvref_t<invoke_result_t<F, decltype(error())>>`.

Constraints: `is_constructible_v<T, decltype(value())>` is true.

Mandates: *G* is a specialization of `expected` and `is_same_v<G::value_type, T>` is true.

Effects: Equivalent to:

```
if (has_value())
    return G(in_place, value());
else
    return invoke(std::forward<F>(f), error());
```

```
template<class F> constexpr auto or_else(F&& f) &&;
template<class F> constexpr auto or_else(F&& f) const &&;
```

Let *G* be `remove_cvref_t<invoke_result_t<F, decltype(std::move(error()))>>`.

Constraints: `is_constructible_v<T, decltype(std::move(value()))>` is true.

Mandates: *G* is a specialization of `expected` and `is_same_v<G::value_type, T>` is true.

Effects: Equivalent to:

```
if (has_value())
    return G(in_place, std::move(value()));
else
    return invoke(std::forward<F>(f), std::move(error()));
```

```
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) const &;
```

Let *U* be `remove_cv_t<invoke_result_t<F, decltype(value())>>`.

Constraints: `is_constructible_v<E, decltype(error())>` is true.

Mandates: *U* is a valid value type for `expected`. If `is_void_v<U>` is false, the declaration

```
U u(invoke(std::forward<F>(f), value()));
```

is well-formed.

Effects:

- If `has_value()` is false, returns `expected<U, E>(unexpected, error())`.
- Otherwise, if `is_void_v<U>` is false, returns an `expected<U, E>` object whose *has_val* member is true and *val* member is direct-non-list-initialized with `invoke(std::forward<F>(f), value())`.
- Otherwise, evaluates `invoke(std::forward<F>(f), value())` and then returns `expected<U, E>()`.

```
template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &&;
```

Let *U* be `remove_cv_t<invoke_result_t<F, decltype(std::move(value()))>>`.

Constraints: `is_constructible_v<E, decltype(std::move(error()))>` is true.

Mandates: *U* is a valid value type for `expected`. If `is_void_v<U>` is false, the declaration

```
U u(invoke(std::forward<F>(f), std::move(value())));
```

is well-formed for some invented variable *u*.

Effects:

- If `has_value()` is false, returns `expected<U, E>(unexpected, std::move(error()))`.
- Otherwise, if `is_void_v<U>` is false, returns an `expected<U, E>` object whose *has_val* member is true and *val* member is direct-non-list-initialized with `invoke(std::forward<F>(f), std::move(value()))`.
- Otherwise, evaluates `invoke(std::forward<F>(f), std::move(value()))` and then returns `expected<U, E>()`.

```
template<class F> constexpr auto transform_error(F&& f) &;
template<class F> constexpr auto transform_error(F&& f) const &;
```

Let *G* be `remove_cv_t<invoke_result_t<F, decltype(error())>>`.

Constraints: `is_constructible_v<T, decltype(value())>` is true.

Mandates: *G* is a valid template argument for `unexpected` (22.8.3.1) and the declaration

```
G g(invoke(std::forward<F>(f), error()));
```

is well-formed.

Returns: If `has_value()` is true, `expected<T, G>(in_place, value())`; otherwise, an `expected<T, G>` object whose *has_val* member is false and *unex* member is direct-non-list-initialized with `invoke(std::forward<F>(f), error())`.

```
template<class F> constexpr auto transform_error(F&& f) &&;
template<class F> constexpr auto transform_error(F&& f) const &&;
```

Let *G* be `remove_cv_t<invoke_result_t<F, decltype(std::move(error()))>>`.

Constraints: `is_constructible_v<T, decltype(std::move(value()))>` is true.

Mandates: *G* is a valid template argument for `unexpected` (22.8.3.1) and the declaration

```
G g(invoke(std::forward<F>(f), std::move(error())));
```

is well-formed.

Returns: If `has_value()` is true, `expected<T, G>(in_place, std::move(value()))`; otherwise, an `expected<T, G>` object whose *has_val* member is false and *unex* member is direct-non-list-initialized with `invoke(std::forward<F>(f), std::move(error()))`.

22.8.6.8 Equality operators

[expected.object.eq]

```
template<class T2, class E2> requires (!is_void_v<T2>)
friend constexpr bool operator==(const expected& x, const expected<T2, E2>& y);
```

Mandates: The expressions `*x == *y` and `x.error() == y.error()` are well-formed and their results are convertible to `bool`.

Returns: If `x.has_value()` does not equal `y.has_value()`, false; otherwise if `x.has_value()` is true, `*x == *y`; otherwise `x.error() == y.error()`.

```
template<class T2> friend constexpr bool operator==(const expected& x, const T2& v);
```

Mandates: The expression `*x == v` is well-formed and its result is convertible to `bool`.

NOTE *T* need not be *Cpp17EqualityComparable*.

Returns: `x.has_value() && static_cast<bool>(*x == v)`.

```
template<class E2> friend constexpr bool operator==(const expected& x, const unexpected<E2>& e);
```

Mandates: The expression `x.error() == e.error()` is well-formed and its result is convertible to `bool`.

Returns: `!x.has_value() && static_cast<bool>(x.error() == e.error())`.

22.8.7 Partial specialization of `expected` for void types

[expected.void]

22.8.7.1 General

[expected.void.general]

```
template<class T, class E> requires is_void_v<T>
class expected<T, E> {
public:
    using value_type = T;
    using error_type = E;
    using unexpected_type = unexpected<E>;

    template<class U>
    using rebind = expected<U, error_type>;
```

```

// 22.8.7.2, constructors
constexpr expected() noexcept;
constexpr expected(const expected&);
constexpr expected(expected&&) noexcept(see below);
template<class U, class G>
    constexpr explicit(see below) expected(const expected<U, G>&);
template<class U, class G>
    constexpr explicit(see below) expected(expected<U, G>&&);

template<class G>
    constexpr explicit(see below) expected(const unexpected<G>&);
template<class G>
    constexpr explicit(see below) expected(unexpected<G>&&);

constexpr explicit expected(in_place_t) noexcept;
template<class... Args>
    constexpr explicit expected(unexpect_t, Args&&...);
template<class U, class... Args>
    constexpr explicit expected(unexpect_t, initializer_list<U>, Args&&...);

// 22.8.7.3, destructor
constexpr ~expected();

// 22.8.7.4, assignment
constexpr expected& operator=(const expected&);
constexpr expected& operator=(expected&&) noexcept(see below);
template<class G>
    constexpr expected& operator=(const unexpected<G>&);
template<class G>
    constexpr expected& operator=(unexpected<G>&&);
constexpr void emplace() noexcept;

// 22.8.7.5, swap
constexpr void swap(expected&) noexcept(see below);
friend constexpr void swap(expected& x, expected& y) noexcept(noexcept(x.swap(y)));

// 22.8.7.6, observers
constexpr explicit operator bool() const noexcept;
constexpr bool has_value() const noexcept;
constexpr void operator*() const noexcept;
constexpr void value() const &;
constexpr void value() &&;
constexpr const E& error() const & noexcept;
constexpr E& error() & noexcept;
constexpr const E&& error() const && noexcept;
constexpr E&& error() && noexcept;
template<class G = E> constexpr E error_or(G&&) const &;
template<class G = E> constexpr E error_or(G&&) &&;

// 22.8.7.7, monadic operations
template<class F> constexpr auto and_then(F&& f) &;
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &;
template<class F> constexpr auto and_then(F&& f) const &&;
template<class F> constexpr auto or_else(F&& f) &;
template<class F> constexpr auto or_else(F&& f) &&;
template<class F> constexpr auto or_else(F&& f) const &;
template<class F> constexpr auto or_else(F&& f) const &&;
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &;
template<class F> constexpr auto transform(F&& f) const &&;
template<class F> constexpr auto transform_error(F&& f) &;

```

```

template<class F> constexpr auto transform_error(F&& f) &&;
template<class F> constexpr auto transform_error(F&& f) const &;
template<class F> constexpr auto transform_error(F&& f) const &&;

// 22.8.7.8, equality operators
template<class T2, class E2> requires is_void_v<T2>
    friend constexpr bool operator==(const expected& x, const expected<T2, E2>& y);
template<class E2>
    friend constexpr bool operator==(const expected&, const unexpected<E2>&);

private:
    bool has_val;           // exposition only
    union {
        E unex;            // exposition only
    };
};

```

Any object of type `expected<T, E>` either represents a value of type `T`, or contains a value of type `E` within its own storage. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate the object of type `E`. Member `has_val` indicates whether the `expected<T, E>` object represents a value of type `T`.

A program that instantiates the definition of the template `expected<T, E>` with a type for the `E` parameter that is not a valid template argument for `unexpected` is ill-formed.

`E` shall meet the requirements of *Cpp17Destructible* (Table 35).

22.8.7.2 Constructors

[expected.void.cons]

```
constexpr expected() noexcept;
```

Postconditions: `has_value()` is true.

```
constexpr expected(const expected& rhs);
```

Effects: If `rhs.has_value()` is false, direct-non-list-initializes `unex` with `rhs.error()`.

Postconditions: `rhs.has_value() == this->has_value()`.

Throws: Any exception thrown by the initialization of `unex`.

Remarks: This constructor is defined as deleted unless `is_copy_constructible_v<E>` is true.

This constructor is trivial if `is_trivially_copy_constructible_v<E>` is true.

```
constexpr expected(expected&& rhs) noexcept(is_nothrow_move_constructible_v<E>);
```

Constraints: `is_move_constructible_v<E>` is true.

Effects: If `rhs.has_value()` is false, direct-non-list-initializes `unex` with `std::move(rhs.error())`.

Postconditions: `rhs.has_value()` is unchanged; `rhs.has_value() == this->has_value()` is true.

Throws: Any exception thrown by the initialization of `unex`.

Remarks: This constructor is trivial if `is_trivially_move_constructible_v<E>` is true.

```

template<class U, class G>
    constexpr explicit(!is_convertible_v<const G&, E>) expected(const expected<U, G>& rhs);
template<class U, class G>
    constexpr explicit(!is_convertible_v<G, E>) expected(expected<U, G>&& rhs);

```

Let `GF` be `const G&` for the first overload and `G` for the second overload.

Constraints:

- `is_void_v<U>` is true; and
- `is_constructible_v<E, GF>` is true; and
- `is_constructible_v<unexpected<E>, expected<U, G>&>` is false; and
- `is_constructible_v<unexpected<E>, expected<U, G>>` is false; and
- `is_constructible_v<unexpected<E>, const expected<U, G>&>` is false; and

— `is_constructible_v<unexpected<E>, const expected<U, G>>` is false.

Effects: If `rhs.has_value()` is false, direct-non-list-initializes `unex` with `std::forward<GF>(rhs.error())`.

Postconditions: `rhs.has_value()` is unchanged; `rhs.has_value() == this->has_value()` is true.

Throws: Any exception thrown by the initialization of `unex`.

```
template<class G>
constexpr explicit(!is_convertible_v<const G&, E>) expected(const unexpected<G>& e);
template<class G>
constexpr explicit(!is_convertible_v<G, E>) expected(unexpected<G>&& e);
```

Let `GF` be `const G&` for the first overload and `G` for the second overload.

Constraints: `is_constructible_v<E, GF>` is true.

Effects: Direct-non-list-initializes `unex` with `std::forward<GF>(e.error())`.

Postconditions: `has_value()` is false.

Throws: Any exception thrown by the initialization of `unex`.

```
constexpr explicit expected(in_place_t) noexcept;
```

Postconditions: `has_value()` is true.

```
template<class... Args>
constexpr explicit expected(unexpect_t, Args&&... args);
```

Constraints: `is_constructible_v<E, Args...>` is true.

Effects: Direct-non-list-initializes `unex` with `std::forward<Args>(args)...`

Postconditions: `has_value()` is false.

Throws: Any exception thrown by the initialization of `unex`.

```
template<class U, class... Args>
constexpr explicit expected(unexpect_t, initializer_list<U> il, Args&&... args);
```

Constraints: `is_constructible_v<E, initializer_list<U>&, Args...>` is true.

Effects: Direct-non-list-initializes `unex` with `il, std::forward<Args>(args)...`

Postconditions: `has_value()` is false.

Throws: Any exception thrown by the initialization of `unex`.

22.8.7.3 Destructor

[`expected.void.dtor`]

```
constexpr ~expected();
```

Effects: If `has_value()` is false, destroys `unex`.

Remarks: If `is_trivially_destructible_v<E>` is true, then this destructor is a trivial destructor.

22.8.7.4 Assignment

[`expected.void.assign`]

```
constexpr expected& operator=(const expected& rhs);
```

Effects:

- If `this->has_value() && rhs.has_value()` is true, no effects.
- Otherwise, if `this->has_value()` is true, equivalent to: `construct_at(addressof(unex), rhs.unex); has_val = false;`
- Otherwise, if `rhs.has_value()` is true, destroys `unex` and sets `has_val` to true.
- Otherwise, equivalent to `unex = rhs.error()`.

Returns: `*this`.

Remarks: This operator is defined as deleted unless `is_copy_assignable_v<E>` is true and `is_copy_constructible_v<E>` is true.

```
constexpr expected& operator=(expected&& rhs) noexcept(see below);
```

Effects:

- If `this->has_value()` && `rhs.has_value()` is true, no effects.
- Otherwise, if `this->has_value()` is true, equivalent to:

```
construct_at(addressof(unex), std::move(rhs.unex));
has_val = false;
```
- Otherwise, if `rhs.has_value()` is true, destroys `unex` and sets `has_val` to true.
- Otherwise, equivalent to `unex = std::move(rhs.error())`.

Returns: `*this`.

Remarks: The exception specification is equivalent to `is_nothrow_move_constructible_v<E> && is_nothrow_move_assignable_v<E>`.

This operator is defined as deleted unless `is_move_constructible_v<E>` is true and `is_move_assignable_v<E>` is true.

```
template<class G>
constexpr expected& operator=(const unexpected<G>& e);
template<class G>
constexpr expected& operator=(unexpected<G>&& e);
```

Let GF be `const G&` for the first overload and `G` for the second overload.

Constraints: `is_constructible_v<E, GF>` is true and `is_assignable_v<E&, GF>` is true.

Effects:

- If `has_value()` is true, equivalent to:

```
construct_at(addressof(unex), std::forward<GF>(e.error()));
has_val = false;
```
- Otherwise, equivalent to: `unex = std::forward<GF>(e.error())`;

Returns: `*this`.

```
constexpr void emplace() noexcept;
```

Effects: If `has_value()` is false, destroys `unex` and sets `has_val` to true.

22.8.7.5 Swap

[expected.void.swap]

```
constexpr void swap(expected& rhs) noexcept(see below);
```

Constraints: `is_swappable_v<E>` is true and `is_move_constructible_v<E>` is true.

Effects: See Table 64.

Table 64 — `swap(expected&)` effects [tab:expected.void.swap]

<code>this->has_value()</code>		<code>!this->has_value()</code>
<code>rhs.has_value()</code>	no effects	calls <code>rhs.swap(*this)</code>
<code>!rhs.has_value()</code>	see below	equivalent to: <code>using std::swap;</code> <code>swap(unex, rhs.unex);</code>

For the case where `rhs.value()` is false and `this->has_value()` is true, equivalent to:

```
construct_at(addressof(unex), std::move(rhs.unex));
destroy_at(addressof(rhs.unex));
has_val = false;
rhs.has_val = true;
```

Throws: Any exception thrown by the expressions in the *Effects*.

Remarks: The exception specification is equivalent to `is_nothrow_move_constructible_v<E> && is_nothrow_swappable_v<E>`.

```
friend constexpr void swap(expected& x, expected& y) noexcept(noexcept(x.swap(y)));
```

Effects: Equivalent to `x.swap(y)`.

22.8.7.6 Observers

[expected.void.obs]

```
constexpr explicit operator bool() const noexcept;
constexpr bool has_value() const noexcept;
```

Returns: `has_val`.

```
constexpr void operator*() const noexcept;
```

Preconditions: `has_value()` is true.

```
constexpr void value() const &;
```

Throws: `bad_expected_access(error())` if `has_value()` is false.

```
constexpr void value() &&;
```

Throws: `bad_expected_access(std::move(error()))` if `has_value()` is false.

```
constexpr const E& error() const & noexcept;
constexpr E& error() & noexcept;
```

Preconditions: `has_value()` is false.

Returns: `unex`.

```
constexpr E&& error() && noexcept;
constexpr const E&& error() const && noexcept;
```

Preconditions: `has_value()` is false.

Returns: `std::move(unex)`.

```
template<class G = E> constexpr E error_or(G&& e) const &;
```

Mandates: `is_copy_constructible_v<E>` is true and `is_convertible_v<G, E>` is true.

Returns: `std::forward<G>(e)` if `has_value()` is true, `error()` otherwise.

```
template<class G = E> constexpr E error_or(G&& e) &&;
```

Mandates: `is_move_constructible_v<E>` is true and `is_convertible_v<G, E>` is true.

Returns: `std::forward<G>(e)` if `has_value()` is true, `std::move(error())` otherwise.

22.8.7.7 Monadic operations

[expected.void.monadic]

```
template<class F> constexpr auto and_then(F&& f) &;
template<class F> constexpr auto and_then(F&& f) const &;
```

Let `U` be `remove_cvref_t<invoke_result_t<F>>`.

Constraints: `is_constructible_v<E, decltype(error())>>` is true.

Mandates: `U` is a specialization of `expected` and `is_same_v<U::error_type, E>` is true.

Effects: Equivalent to:

```
if (has_value())
    return invoke(std::forward<F>(f));
else
    return U(unexpect, error());
```

```
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &&;
```

Let `U` be `remove_cvref_t<invoke_result_t<F>>`.

Constraints: `is_constructible_v<E, decltype(std::move(error()))>` is true.

Mandates: `U` is a specialization of `expected` and `is_same_v<U::error_type, E>` is true.

Effects: Equivalent to:

```

    if (has_value())
        return invoke(std::forward<F>(f));
    else
        return U(unexpect, std::move(error()));

template<class F> constexpr auto or_else(F&& f) &;
template<class F> constexpr auto or_else(F&& f) const &;

```

Let *G* be `remove_cvref_t<invoke_result_t<F, decltype(error())>>`.

Mandates: *G* is a specialization of `expected` and `is_same_v<G::value_type, T>` is true.

Effects: Equivalent to:

```

    if (has_value())
        return G();
    else
        return invoke(std::forward<F>(f), error());

template<class F> constexpr auto or_else(F&& f) &&;
template<class F> constexpr auto or_else(F&& f) const &&;

```

Let *G* be `remove_cvref_t<invoke_result_t<F, decltype(std::move(error()))>>`.

Mandates: *G* is a specialization of `expected` and `is_same_v<G::value_type, T>` is true.

Effects: Equivalent to:

```

    if (has_value())
        return G();
    else
        return invoke(std::forward<F>(f), std::move(error()));

template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) const &;

```

Let *U* be `remove_cv_t<invoke_result_t<F>>`.

Constraints: `is_constructible_v<E, decltype(error())>` is true.

Mandates: *U* is a valid value type for `expected`. If `is_void_v<U>` is false, the declaration

```
U u(invoke(std::forward<F>(f)));
```

is well-formed.

Effects:

- If `has_value()` is false, returns `expected<U, E>(unexpect, error())`.
- Otherwise, if `is_void_v<U>` is false, returns an `expected<U, E>` object whose *has_val* member is true and *val* member is direct-non-list-initialized with `invoke(std::forward<F>(f))`.
- Otherwise, evaluates `invoke(std::forward<F>(f))` and then returns `expected<U, E>()`.

```

template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &&;

```

Let *U* be `remove_cv_t<invoke_result_t<F>>`.

Constraints: `is_constructible_v<E, decltype(std::move(error()))>` is true.

Mandates: *U* is a valid value type for `expected`. If `is_void_v<U>` is false, the declaration

```
U u(invoke(std::forward<F>(f)));
```

is well-formed.

Effects:

- If `has_value()` is false, returns `expected<U, E>(unexpect, std::move(error()))`.
- Otherwise, if `is_void_v<U>` is false, returns an `expected<U, E>` object whose *has_val* member is true and *val* member is direct-non-list-initialized with `invoke(std::forward<F>(f))`.
- Otherwise, evaluates `invoke(std::forward<F>(f))` and then returns `expected<U, E>()`.

```
template<class F> constexpr auto transform_error(F&& f) &;
```

```
template<class F> constexpr auto transform_error(F&& f) const &;
```

Let *G* be `remove_cv_t<invoke_result_t<F, decltype(error())>>`.

Mandates: *G* is a valid template argument for `unexpected` (22.8.3.1) and the declaration

```
G g(invoke(std::forward<F>(f), error()));
```

is well-formed.

Returns: If `has_value()` is true, `expected<T, G>()`; otherwise, an `expected<T, G>` object whose `has_val` member is false and `unex` member is direct-non-list-initialized with `invoke(std::forward<F>(f), error())`.

```
template<class F> constexpr auto transform_error(F&& f) &&;
```

```
template<class F> constexpr auto transform_error(F&& f) const &&;
```

Let *G* be `remove_cv_t<invoke_result_t<F, decltype(std::move(error()))>>`.

Mandates: *G* is a valid template argument for `unexpected` (22.8.3.1) and the declaration

```
G g(invoke(std::forward<F>(f), std::move(error())));
```

is well-formed.

Returns: If `has_value()` is true, `expected<T, G>()`; otherwise, an `expected<T, G>` object whose `has_val` member is false and `unex` member is direct-non-list-initialized with `invoke(std::forward<F>(f), std::move(error()))`.

22.8.7.8 Equality operators

[expected.void.eq]

```
template<class T2, class E2> requires is_void_v<T2>
```

```
friend constexpr bool operator==(const expected& x, const expected<T2, E2>& y);
```

Mandates: The expression `x.error() == y.error()` is well-formed and its result is convertible to `bool`.

Returns: If `x.has_value()` does not equal `y.has_value()`, false; otherwise `x.has_value() || static_cast<bool>(x.error() == y.error())`.

```
template<class E2>
```

```
friend constexpr bool operator==(const expected& x, const unexpected<E2>& e);
```

Mandates: The expression `x.error() == e.error()` is well-formed and its result is convertible to `bool`.

Returns: `!x.has_value() && static_cast<bool>(x.error() == e.error())`.

22.9 Bitsets

[bitset]

22.9.1 Header <bitset> synopsis

[bitset.syn]

The header <bitset> defines a class template and several related functions for representing and manipulating fixed-size sequences of bits.

```
#include <string> // see 23.4.2
```

```
#include <iosfwd> // for istream (31.7.1), ostream (31.7.2), see 31.3.1
```

```
namespace std {
```

```
    template<size_t N> class bitset;
```

```
    // 22.9.4, bitset operators
```

```
    template<size_t N>
```

```
        constexpr bitset<N> operator&(const bitset<N>&, const bitset<N>&) noexcept;
```

```
    template<size_t N>
```

```
        constexpr bitset<N> operator|(const bitset<N>&, const bitset<N>&) noexcept;
```

```
    template<size_t N>
```

```
        constexpr bitset<N> operator^(const bitset<N>&, const bitset<N>&) noexcept;
```

```
    template<class charT, class traits, size_t N>
```

```
        basic_istream<charT, traits>&
```

```
            operator>>(basic_istream<charT, traits>& is, bitset<N>& x);
```

```

template<class charT, class traits, size_t N>
    basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);
}

```

22.9.2 Class template bitset

[template.bitset]

22.9.2.1 General

[template.bitset.general]

```

namespace std {
    template<size_t N> class bitset {
    public:
        // bit reference
        class reference {
        friend class bitset;
        constexpr reference() noexcept;

    public:
        constexpr reference(const reference&) = default;
        constexpr ~reference();
        constexpr reference& operator=(bool x) noexcept;           // for b[i] = x;
        constexpr reference& operator=(const reference&) noexcept;  // for b[i] = b[j];
        constexpr bool operator~() const noexcept;                 // flips the bit
        constexpr operator bool() const noexcept;                  // for x = b[i];
        constexpr reference& flip() noexcept;                       // for b[i].flip();
        };

    // 22.9.2.2, constructors
    constexpr bitset() noexcept;
    constexpr bitset(unsigned long long val) noexcept;
    template<class charT, class traits, class Allocator>
        constexpr explicit bitset(
            const basic_string<charT, traits, Allocator>& str,
            typename basic_string<charT, traits, Allocator>::size_type pos = 0,
            typename basic_string<charT, traits, Allocator>::size_type n
                = basic_string<charT, traits, Allocator>::npos,
            charT zero = charT('0'),
            charT one = charT('1'));
    template<class charT>
        constexpr explicit bitset(
            const charT* str,
            typename basic_string<charT>::size_type n = basic_string<charT>::npos,
            charT zero = charT('0'),
            charT one = charT('1'));

    // 22.9.2.3, bitset operations
    constexpr bitset& operator&=(const bitset& rhs) noexcept;
    constexpr bitset& operator|=(const bitset& rhs) noexcept;
    constexpr bitset& operator^=(const bitset& rhs) noexcept;
    constexpr bitset& operator<=(size_t pos) noexcept;
    constexpr bitset& operator>=(size_t pos) noexcept;
    constexpr bitset& operator<<(size_t pos) const noexcept;
    constexpr bitset& operator>>(size_t pos) const noexcept;
    constexpr bitset& set() noexcept;
    constexpr bitset& set(size_t pos, bool val = true);
    constexpr bitset& reset() noexcept;
    constexpr bitset& reset(size_t pos);
    constexpr bitset& operator~() const noexcept;
    constexpr bitset& flip() noexcept;
    constexpr bitset& flip(size_t pos);

    // element access
    constexpr bool operator[](size_t pos) const;
    constexpr reference operator[](size_t pos);
}

```

```
constexpr unsigned long to_ulong() const;
constexpr unsigned long long to_ullong() const;
template<class charT = char,
        class traits = char_traits<charT>,
        class Allocator = allocator<charT>>
constexpr basic_string<charT, traits, Allocator>
    to_string(charT zero = charT('0'), charT one = charT('1')) const;

// observers
constexpr size_t count() const noexcept;
constexpr size_t size() const noexcept;
constexpr bool operator==(const bitset& rhs) const noexcept;
constexpr bool test(size_t pos) const;
constexpr bool all() const noexcept;
constexpr bool any() const noexcept;
constexpr bool none() const noexcept;
};

// 22.9.3, hash support
template<class T> struct hash;
template<size_t N> struct hash<bitset<N>>;
}
```

The class template `bitset<N>` describes an object that can store a sequence consisting of a fixed number of bits, `N`.

Each bit represents either the value zero (reset) or one (set). To *toggle* a bit is to change the value zero to one, or the value one to zero. Each bit has a non-negative position `pos`. When converting between an object of class `bitset<N>` and a value of some integral type, bit position `pos` corresponds to the *bit value* `1 << pos`. The integral value corresponding to two or more bits is the sum of their bit values.

The functions described in 22.9.2 can report three kinds of errors, each associated with a distinct exception:

- an *invalid-argument* error is associated with exceptions of type `invalid_argument` (19.2.5);
- an *out-of-range* error is associated with exceptions of type `out_of_range` (19.2.7);
- an *overflow* error is associated with exceptions of type `overflow_error` (19.2.10).

22.9.2.2 Constructors

[bitset.cons]

```
constexpr bitset() noexcept;
```

Effects: Initializes all bits in `*this` to zero.

```
constexpr bitset(unsigned long long val) noexcept;
```

Effects: Initializes the first `M` bit positions to the corresponding bit values in `val`. `M` is the smaller of `N` and the number of bits in the value representation (6.8.1) of `unsigned long long`. If `M < N`, the remaining bit positions are initialized to zero.

```
template<class charT, class traits, class Allocator>
constexpr explicit bitset(
    const basic_string<charT, traits, Allocator>& str,
    typename basic_string<charT, traits, Allocator>::size_type pos = 0,
    typename basic_string<charT, traits, Allocator>::size_type n
        = basic_string<charT, traits, Allocator>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));
```

Effects: Determines the effective length `rlen` of the initializing string as the smaller of `n` and `str.size()` – `pos`. Initializes the first `M` bit positions to values determined from the corresponding characters in the string `str`. `M` is the smaller of `N` and `rlen`.

An element of the constructed object has value zero if the corresponding character in `str`, beginning at position `pos`, is `zero`. Otherwise, the element has the value one. Character position `pos + M – 1` corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions.

If $M < N$, remaining bit positions are initialized to zero.

The function uses `traits::eq` to compare the character values.

Throws: `out_of_range` if `pos > str.size()` or `invalid_argument` if any of the `rlen` characters in `str` beginning at position `pos` is other than zero or one.

```
template<class charT>
constexpr explicit bitset(
    const charT* str,
    typename basic_string<charT>::size_type n = basic_string<charT>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));
```

Effects: As if by:

```
    bitset(n == basic_string<charT>::npos
        ? basic_string<charT>(str)
        : basic_string<charT>(str, n),
        0, n, zero, one)
```

22.9.2.3 Members

[`bitset.members`]

```
constexpr bitset& operator&=(const bitset& rhs) noexcept;
```

Effects: Clears each bit in `*this` for which the corresponding bit in `rhs` is clear, and leaves all other bits unchanged.

Returns: `*this`.

```
constexpr bitset& operator|=(const bitset& rhs) noexcept;
```

Effects: Sets each bit in `*this` for which the corresponding bit in `rhs` is set, and leaves all other bits unchanged.

Returns: `*this`.

```
constexpr bitset& operator^=(const bitset& rhs) noexcept;
```

Effects: Toggles each bit in `*this` for which the corresponding bit in `rhs` is set, and leaves all other bits unchanged.

Returns: `*this`.

```
constexpr bitset& operator<<=(size_t pos) noexcept;
```

Effects: Replaces each bit at position `I` in `*this` with a value determined as follows:

- If $I < pos$, the new value is zero;
- If $I \geq pos$, the new value is the previous value of the bit at position $I - pos$.

Returns: `*this`.

```
constexpr bitset& operator>>=(size_t pos) noexcept;
```

Effects: Replaces each bit at position `I` in `*this` with a value determined as follows:

- If $pos \geq N - I$, the new value is zero;
- If $pos < N - I$, the new value is the previous value of the bit at position $I + pos$.

Returns: `*this`.

```
constexpr bitset operator<<(size_t pos) const noexcept;
```

Returns: `bitset(*this) <<= pos`.

```
constexpr bitset operator>>(size_t pos) const noexcept;
```

Returns: `bitset(*this) >>= pos`.

```
constexpr bitset& set() noexcept;
```

Effects: Sets all bits in `*this`.

Returns: `*this`.

```
constexpr bitset& set(size_t pos, bool val = true);
```

Effects: Stores a new value in the bit at position `pos` in `*this`. If `val` is `true`, the stored value is one, otherwise it is zero.

Returns: `*this`.

Throws: `out_of_range` if `pos` does not correspond to a valid bit position.

```
constexpr bitset& reset() noexcept;
```

Effects: Resets all bits in `*this`.

Returns: `*this`.

```
constexpr bitset& reset(size_t pos);
```

Effects: Resets the bit at position `pos` in `*this`.

Returns: `*this`.

Throws: `out_of_range` if `pos` does not correspond to a valid bit position.

```
constexpr bitset operator~() const noexcept;
```

Effects: Constructs an object `x` of class `bitset` and initializes it with `*this`.

Returns: `x.flip()`.

```
constexpr bitset& flip() noexcept;
```

Effects: Toggles all bits in `*this`.

Returns: `*this`.

```
constexpr bitset& flip(size_t pos);
```

Effects: Toggles the bit at position `pos` in `*this`.

Returns: `*this`.

Throws: `out_of_range` if `pos` does not correspond to a valid bit position.

```
constexpr bool operator[](size_t pos) const;
```

Preconditions: `pos` is valid.

Returns: `true` if the bit at position `pos` in `*this` has the value one, otherwise `false`.

Throws: Nothing.

```
constexpr bitset::reference operator[](size_t pos);
```

Preconditions: `pos` is valid.

Returns: An object of type `bitset::reference` such that `(*this)[pos] == this->test(pos)`, and such that `(*this)[pos] = val` is equivalent to `this->set(pos, val)`.

Throws: Nothing.

Remarks: For the purpose of determining the presence of a data race (6.9.2), any access or update through the resulting reference potentially accesses or modifies, respectively, the entire underlying `bitset`.

```
constexpr unsigned long to_ulong() const;
```

Returns: `x`.

Throws: `overflow_error` if the integral value `x` corresponding to the bits in `*this` cannot be represented as type `unsigned long`.

```
constexpr unsigned long long to_ullong() const;
```

Returns: `x`.

Throws: `overflow_error` if the integral value `x` corresponding to the bits in `*this` cannot be represented as type `unsigned long long`.

```
template<class charT = char,
        class traits = char_traits<charT>,
        class Allocator = allocator<charT>>
constexpr basic_string<charT, traits, Allocator>
to_string(charT zero = charT('0'), charT one = charT('1')) const;
```

Effects: Constructs a string object of the appropriate type and initializes it to a string of length *N* characters. Each character is determined by the value of its corresponding bit position in **this*. Character position *N* - 1 corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions. Bit value zero becomes the character **zero**, bit value one becomes the character **one**.

Returns: The created object.

```
constexpr size_t count() const noexcept;
```

Returns: A count of the number of bits set in **this*.

```
constexpr size_t size() const noexcept;
```

Returns: *N*.

```
constexpr bool operator==(const bitset& rhs) const noexcept;
```

Returns: true if the value of each bit in **this* equals the value of the corresponding bit in *rhs*.

```
constexpr bool test(size_t pos) const;
```

Returns: true if the bit at position *pos* in **this* has the value one.

Throws: `out_of_range` if *pos* does not correspond to a valid bit position.

```
constexpr bool all() const noexcept;
```

Returns: `count() == size()`.

```
constexpr bool any() const noexcept;
```

Returns: `count() != 0`.

```
constexpr bool none() const noexcept;
```

Returns: `count() == 0`.

22.9.3 bitset hash support

[bitset.hash]

```
template<size_t N> struct hash<bitset<N>>;
```

The specialization is enabled (22.10.19).

22.9.4 bitset operators

[bitset.operators]

```
template<size_t N>
constexpr bitset<N> operator&(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
```

Returns: `bitset<N>(lhs) &= rhs`.

```
template<size_t N>
constexpr bitset<N> operator|(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
```

Returns: `bitset<N>(lhs) |= rhs`.

```
template<size_t N>
constexpr bitset<N> operator^(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
```

Returns: `bitset<N>(lhs) ^= rhs`.

```
template<class charT, class traits, size_t N>
basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, bitset<N>& x);
```

A formatted input function (31.7.5.3).

Effects: Extracts up to *N* characters from *is*. Stores these characters in a temporary object *str* of type `basic_string<charT, traits>`, then evaluates the expression `x = bitset<N>(str)`. Characters are extracted and stored until any of the following occurs:

- *N* characters have been extracted and stored;
- end-of-file occurs on the input sequence;
- the next input character is neither `is.widen('0')` nor `is.widen('1')` (in which case the input character is not extracted).

If *N* > 0 and no characters are stored in *str*, `ios_base::failbit` is set in the input function's local error state before `setstate` is called.

Returns: *is*.

```
template<class charT, class traits, size_t N>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);
```

Returns:

```
os << x.template to_string<charT, traits, allocator<charT>>(
    use_facet<ctype<charT>>(os.getloc()).widen('0'),
    use_facet<ctype<charT>>(os.getloc()).widen('1'))
(see 31.7.6.3).
```

22.10 Function objects

[function.objects]

22.10.1 General

[function.objects.general]

A *function object type* is an object type (6.8.1) that can be the type of the *postfix-expression* in a function call (7.6.1.3, 12.2.2.2).²⁰³ A *function object* is an object of a function object type. In the places where one would expect to pass a pointer to a function to an algorithmic template (Clause 27), the interface is specified to accept a function object. This not only makes algorithmic templates work with pointers to functions, but also enables them to work with arbitrary function objects.

22.10.2 Header <functional> synopsis

[functional.syn]

```
namespace std {
    // 22.10.5, invoke
    template<class F, class... Args>
        constexpr invoke_result_t<F, Args...> invoke(F&& f, Args&&... args) // freestanding
            noexcept(is_nothrow_invocable_v<F, Args...>);

    template<class R, class F, class... Args>
        constexpr R invoke_r(F&& f, Args&&... args) // freestanding
            noexcept(is_nothrow_invocable_r_v<R, F, Args...>);

    // 22.10.6, reference_wrapper
    template<class T> class reference_wrapper; // freestanding

    template<class T> constexpr reference_wrapper<T> ref(T&) noexcept; // freestanding
    template<class T> constexpr reference_wrapper<const T> cref(const T&) noexcept; // freestanding

```

// 22.10.15, bind
template<class T> struct is_bind_expression; // freestanding
template<class T>
    constexpr bool is_bind_expression_v = // freestanding
        is_bind_expression<T>::value;
template<class T> struct is_placeholder; // freestanding
template<class T>
    constexpr int is_placeholder_v = // freestanding
        is_placeholder<T>::value;

template<class F, class... BoundArgs>
    constexpr unspecified bind(F&&, BoundArgs&&...); // freestanding
template<class R, class F, class... BoundArgs>
    constexpr unspecified bind(F&&, BoundArgs&&...); // freestanding

namespace placeholders {
    // M is the implementation-defined number of placeholders
    see below _1; // freestanding
    see below _2; // freestanding
    .
    .
    .
    see below _M; // freestanding
}

// 22.10.16, member function adaptors
template<class R, class T>
    constexpr unspecified mem_fn(R T::*) noexcept; // freestanding

// 22.10.17, polymorphic function wrappers
class bad_function_call;

template<class> class function; // not defined
template<class R, class... ArgTypes> class function<R(ArgTypes...)>;

// 22.10.17.3.8, specialized algorithms
template<class R, class... ArgTypes>
    void swap(function<R(ArgTypes...)>&, function<R(ArgTypes...)>&) noexcept;

// 22.10.17.3.7, null pointer comparison operator functions
template<class R, class... ArgTypes>
    bool operator==(const function<R(ArgTypes...)>&, nullptr_t) noexcept;

// 22.10.17.4, move only wrapper
template<class... S> class move_only_function; // not defined
template<class R, class... ArgTypes>
    class move_only_function<R(ArgTypes...) cv ref noexcept(noex)>; // see below

// 22.10.18, searchers
template<class ForwardIterator1, class BinaryPredicate = equal_to<>>
    class default_searcher; // freestanding

template<class RandomAccessIterator,
    class Hash = hash<typename iterator_traits<RandomAccessIterator>::value_type>,
    class BinaryPredicate = equal_to<>>
    class boyer_moore_searcher;

template<class RandomAccessIterator,
    class Hash = hash<typename iterator_traits<RandomAccessIterator>::value_type>,
    class BinaryPredicate = equal_to<>>
    class boyer_moore_horspool_searcher;

```

```

// 22.10.19, class template hash
template<class T>
    struct hash; // freestanding

namespace ranges {
    // 22.10.9, concept-constrained comparisons
    struct equal_to; // freestanding
    struct not_equal_to; // freestanding
    struct greater; // freestanding
    struct less; // freestanding
    struct greater_equal; // freestanding
    struct less_equal; // freestanding
}
}

```

EXAMPLE 1 If a C++ program wants to have a by-element addition of two vectors **a** and **b** containing **double** and put the result into **a**, it can do:

```
transform(a.begin(), a.end(), b.begin(), a.begin(), plus<double>());
```

EXAMPLE 2 To negate every element of **a**:

```
transform(a.begin(), a.end(), a.begin(), negate<double>());
```

22.10.3 Definitions

[func.def]

The following definitions apply to this Clause:

A *call signature* is the name of a return type followed by a parenthesized comma-separated list of zero or more argument types.

A *callable type* is a function object type (22.10) or a pointer to member.

A *callable object* is an object of a callable type.

A *call wrapper type* is a type that holds a callable object and supports a call operation that forwards to that object.

A *call wrapper* is an object of a call wrapper type.

A *target object* is the callable object held by a call wrapper.

A call wrapper type may additionally hold a sequence of objects and references that may be passed as arguments to the target object. These entities are collectively referred to as *bound argument entities*.

The target object and bound argument entities of the call wrapper are collectively referred to as *state entities*.

22.10.4 Requirements

[func.require]

Define *INVOKE*(*f*, *t*₁, *t*₂, ..., *t*_{*N*}) as follows:

- (*t*₁.**f*)(*t*₂, ..., *t*_{*N*}) when *f* is a pointer to a member function of a class *T* and *is_same_v*<*T*, *remove_cvref_t*<*decltype*(*t*₁)>> || *is_base_of_v*<*T*, *remove_cvref_t*<*decltype*(*t*₁)>> is true;
- (*t*₁.get().**f*)(*t*₂, ..., *t*_{*N*}) when *f* is a pointer to a member function of a class *T* and *remove_cvref_t*<*decltype*(*t*₁)> is a specialization of *reference_wrapper*;
- ((**t*₁).**f*)(*t*₂, ..., *t*_{*N*}) when *f* is a pointer to a member function of a class *T* and *t*₁ does not satisfy the previous two items;
- *t*₁.**f* when *N* = 1 and *f* is a pointer to data member of a class *T* and *is_same_v*<*T*, *remove_cvref_t*<*decltype*(*t*₁)>> || *is_base_of_v*<*T*, *remove_cvref_t*<*decltype*(*t*₁)>> is true;
- *t*₁.get().**f* when *N* = 1 and *f* is a pointer to data member of a class *T* and *remove_cvref_t*<*decltype*(*t*₁)> is a specialization of *reference_wrapper*;
- (**t*₁).**f* when *N* = 1 and *f* is a pointer to data member of a class *T* and *t*₁ does not satisfy the previous two items;
- *f*(*t*₁, *t*₂, ..., *t*_{*N*}) in all other cases.

Define *INVOKE*<*R*>(f, *t*₁, *t*₂, ..., *t*_{*N*}) as *static_cast*<*void*>(*INVOKE*(f, *t*₁, *t*₂, ..., *t*_{*N*})) if *R* is *cv void*, otherwise *INVOKE*(f, *t*₁, *t*₂, ..., *t*_{*N*}) implicitly converted to *R*. If *reference_converts_from_temporary_v*<*R*, *decltype*(*INVOKE*(f, *t*₁, *t*₂, ..., *t*_{*N*}))> is true, *INVOKE*<*R*>(f, *t*₁, *t*₂, ..., *t*_{*N*}) is ill-formed.

Every call wrapper (22.10.3) meets the *Cpp17MoveConstructible* and *Cpp17Destructible* requirements. An *argument forwarding call wrapper* is a call wrapper that can be called with an arbitrary argument list and delivers the arguments to the target object as references. This forwarding step delivers rvalue arguments as rvalue references and lvalue arguments as lvalue references.

NOTE 1 In a typical implementation, argument forwarding call wrappers have an overloaded function call operator of the form

```
template<class... UnBoundArgs>
constexpr R operator()(UnBoundArgs&&... unbound_args) cv-qual;
```

A *perfect forwarding call wrapper* is an argument forwarding call wrapper that forwards its state entities to the underlying call expression. This forwarding step delivers a state entity of type *T* as *cv T&* when the call is performed on an lvalue of the call wrapper type and as *cv T&&* otherwise, where *cv* represents the cv-qualifiers of the call wrapper and where *cv* shall be neither *volatile* nor *const volatile*.

A *call pattern* defines the semantics of invoking a perfect forwarding call wrapper. A postfix call performed on a perfect forwarding call wrapper is expression-equivalent (3.20) to an expression *e* determined from its call pattern *cp* by replacing all occurrences of the arguments of the call wrapper and its state entities with references as described in the corresponding forwarding steps.

A *simple call wrapper* is a perfect forwarding call wrapper that meets the *Cpp17CopyConstructible* and *Cpp17CopyAssignable* requirements and whose copy constructor, move constructor, and assignment operators are *constexpr* functions that do not throw exceptions.

The copy/move constructor of an argument forwarding call wrapper has the same apparent semantics as if memberwise copy/move of its state entities were performed (11.4.5.3).

NOTE 2 This implies that each of the copy/move constructors has the same exception-specification as the corresponding implicit definition and is declared as *constexpr* if the corresponding implicit definition would be considered to be *constexpr*.

Argument forwarding call wrappers returned by a given standard library function template have the same type if the types of their corresponding state entities are the same.

22.10.5 invoke functions

[func.invoke]

```
template<class F, class... Args>
constexpr invoke_result_t<F, Args...> invoke(F&& f, Args&&... args)
noexcept(is_nothrow_invocable_v<F, Args...>);

Constraints: is_invocable_v<F, Args...> is true.

Returns: INVOKE(std::forward<F>(f), std::forward<Args>(args)...) (22.10.4).

template<class R, class F, class... Args>
constexpr R invoke_r(F&& f, Args&&... args)
noexcept(is_nothrow_invocable_r_v<R, F, Args...>);

Constraints: is_invocable_r_v<R, F, Args...> is true.

Returns: INVOKE<R>(std::forward<F>(f), std::forward<Args>(args)...) (22.10.4).
```

22.10.6 Class template reference_wrapper

[refwrap]

22.10.6.1 General

[refwrap.general]

```
namespace std {
template<class T> class reference_wrapper {
public:
// types
using type = T;

// 22.10.6.2, constructors
template<class U>
constexpr reference_wrapper(U&&) noexcept(see below);
constexpr reference_wrapper(const reference_wrapper& x) noexcept;

// 22.10.6.3, assignment
constexpr reference_wrapper& operator=(const reference_wrapper& x) noexcept;
```

```

// 22.10.6.4, access
constexpr operator T& () const noexcept;
constexpr T& get() const noexcept;

// 22.10.6.5, invocation
template<class... ArgTypes>
constexpr invoke_result_t<T&, ArgTypes...> operator()(ArgTypes&&...) const
noexcept(is_nothrow_invocable_v<T&, ArgTypes...>);
};

template<class T>
reference_wrapper(T&) -> reference_wrapper<T>;
}

```

`reference_wrapper<T>` is a *Cpp17CopyConstructible* and *Cpp17CopyAssignable* wrapper around a reference to an object or function of type `T`.

`reference_wrapper<T>` is a trivially copyable type (6.8.1).

The template parameter `T` of `reference_wrapper` may be an incomplete type.

22.10.6.2 Constructors

[refwrap.const]

```

template<class U>
constexpr reference_wrapper(U&& u) noexcept(see below);

```

Let *FUN* denote the exposition-only functions

```

void FUN(T&) noexcept;
void FUN(T&&) = delete;

```

Constraints: The expression `FUN(declval<U>())` is well-formed and `is_same_v<remove_cvref_t<U>, reference_wrapper>` is false.

Effects: Creates a variable `r` as if by `T& r = std::forward<U>(u)`, then constructs a `reference_wrapper` object that stores a reference to `r`.

Remarks: The exception specification is equivalent to `noexcept(FUN(declval<U>()))`.

```

constexpr reference_wrapper(const reference_wrapper& x) noexcept;

```

Effects: Constructs a `reference_wrapper` object that stores a reference to `x.get()`.

22.10.6.3 Assignment

[refwrap.assign]

```

constexpr reference_wrapper& operator=(const reference_wrapper& x) noexcept;

```

Postconditions: `*this` stores a reference to `x.get()`.

22.10.6.4 Access

[refwrap.access]

```

constexpr operator T& () const noexcept;

```

Returns: The stored reference.

```

constexpr T& get() const noexcept;

```

Returns: The stored reference.

22.10.6.5 Invocation

[refwrap.invoke]

```

template<class... ArgTypes>
constexpr invoke_result_t<T&, ArgTypes...>
operator()(ArgTypes&&... args) const noexcept(is_nothrow_invocable_v<T&, ArgTypes...>);

```

Mandates: `T` is a complete type.

Returns: `INVOKE(get(), std::forward<ArgTypes>(args)...) (22.10.4)`

22.10.6.6 Helper functions

[refwrap.helpers]

The template parameter `T` of the following `ref` and `cref` function templates may be an incomplete type.

```
template<class T> constexpr reference_wrapper<T> ref(T& t) noexcept;
```

Returns: reference_wrapper<T>(t).

```
template<class T> constexpr reference_wrapper<T> ref(reference_wrapper<T> t) noexcept;
```

Returns: t.

```
template<class T> constexpr reference_wrapper<const T> cref(const T& t) noexcept;
```

Returns: reference_wrapper<const T>(t).

```
template<class T> constexpr reference_wrapper<const T> cref(reference_wrapper<T> t) noexcept;
```

Returns: t.

22.10.6.7 common_reference related specializations

[refwrap.common.ref]

```
namespace std {
    template<class T>
        constexpr bool is-ref-wrapper = false; // exposition only

    template<class T>
        constexpr bool is-ref-wrapper<reference_wrapper<T>> = true;

    template<class R, class T, class RQ, class TQ>
        concept ref-wrap-common-reference-exists-with = // exposition only
            is-ref-wrapper<R> &&
            requires { typename common_reference_t<typename R::type&, TQ>; } &&
            convertible_to<RQ, common_reference_t<typename R::type&, TQ>>;

    template<class R, class T, template<class> class RQual, template<class> class TQual>
        requires (ref-wrap-common-reference-exists-with<R, T, RQual<R>, TQual<T>> &&
            !ref-wrap-common-reference-exists-with<T, R, TQual<T>, RQual<R>>)
    struct basic_common_reference<R, T, RQual, TQual> {
        using type = common_reference_t<typename R::type&, TQual<T>>;
    };

    template<class T, class R, template<class> class TQual, template<class> class RQual>
        requires (ref-wrap-common-reference-exists-with<R, T, RQual<R>, TQual<T>> &&
            !ref-wrap-common-reference-exists-with<T, R, TQual<T>, RQual<R>>)
    struct basic_common_reference<T, R, TQual, RQual> {
        using type = common_reference_t<typename R::type&, TQual<T>>;
    };
}
```

22.10.7 Arithmetic operations

[arithmetic.operations]

22.10.7.1 General

[arithmetic.operations.general]

The library provides basic function object classes for all of the arithmetic operators in the language (7.6.5, 7.6.6).

22.10.7.2 Class template plus

[arithmetic.operations.plus]

```
template<class T = void> struct plus {
    constexpr T operator()(const T& x, const T& y) const;
};
```

```
constexpr T operator()(const T& x, const T& y) const;
```

Returns: x + y.

```
template<> struct plus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) + std::forward<U>(u));

    using is_transparent = unspecified;
};
```

```
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) + std::forward<U>(u));

Returns: std::forward<T>(t) + std::forward<U>(u).
```

22.10.7.3 Class template minus

[arithmetic.operations.minus]

```
template<class T = void> struct minus {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: x - y.

template<> struct minus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) - std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) - std::forward<U>(u));

Returns: std::forward<T>(t) - std::forward<U>(u).
```

22.10.7.4 Class template multiplies

[arithmetic.operations.multiplies]

```
template<class T = void> struct multiplies {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: x * y.

template<> struct multiplies<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) * std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) * std::forward<U>(u));

Returns: std::forward<T>(t) * std::forward<U>(u).
```

22.10.7.5 Class template divides

[arithmetic.operations.divides]

```
template<class T = void> struct divides {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: x / y.

template<> struct divides<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) / std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) / std::forward<U>(u));

Returns: std::forward<T>(t) / std::forward<U>(u).
```

22.10.7.6 Class template modulus**[arithmetic.operations.modulus]**

```
template<class T = void> struct modulus {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
    Returns: x % y.

template<> struct modulus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) % std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) % std::forward<U>(u));
    Returns: std::forward<T>(t) % std::forward<U>(u).
```

22.10.7.7 Class template negate**[arithmetic.operations.negate]**

```
template<class T = void> struct negate {
    constexpr T operator()(const T& x) const;
};

constexpr T operator()(const T& x) const;
    Returns: -x.

template<> struct negate<void> {
    template<class T> constexpr auto operator()(T&& t) const
        -> decltype(-std::forward<T>(t));

    using is_transparent = unspecified;
};

template<class T> constexpr auto operator()(T&& t) const
    -> decltype(-std::forward<T>(t));
    Returns: -std::forward<T>(t).
```

22.10.8 Comparisons**[comparisons]****22.10.8.1 General****[comparisons.general]**

The library provides basic function object classes for all of the comparison operators in the language (7.6.9, 7.6.10).

For templates `less`, `greater`, `less_equal`, and `greater_equal`, the specializations for any pointer type yield a result consistent with the implementation-defined strict total order over pointers (3.26).

NOTE If `a < b` is well-defined for pointers `a` and `b` of type `P`, then `(a < b) == less<P>()(a, b)`, `(a > b) == greater<P>()(a, b)`, and so forth.

For template specializations `less<void>`, `greater<void>`, `less_equal<void>`, and `greater_equal<void>`, if the call operator calls a built-in operator comparing pointers, the call operator yields a result consistent with the implementation-defined strict total order over pointers.

22.10.8.2 Class template equal_to**[comparisons.equal.to]**

```
template<class T = void> struct equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
    Returns: x == y.
```

```
template<> struct equal_to<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) == std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) == std::forward<U>(u));

Returns: std::forward<T>(t) == std::forward<U>(u).
```

22.10.8.3 Class template not_equal_to

[comparisons.not.equal.to]

```
template<class T = void> struct not_equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

Returns: x != y.
```

```
template<> struct not_equal_to<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) != std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) != std::forward<U>(u));

Returns: std::forward<T>(t) != std::forward<U>(u).
```

22.10.8.4 Class template greater

[comparisons.greater]

```
template<class T = void> struct greater {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

Returns: x > y.

template<> struct greater<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) > std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) > std::forward<U>(u));

Returns: std::forward<T>(t) > std::forward<U>(u).
```

22.10.8.5 Class template less

[comparisons.less]

```
template<class T = void> struct less {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

Returns: x < y.

template<> struct less<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) < std::forward<U>(u));
```

```

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) < std::forward<U>(u));

    Returns: std::forward<T>(t) < std::forward<U>(u).

```

22.10.8.6 Class template greater_equal

[comparisons.greater.equal]

```

template<class T = void> struct greater_equal {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

    Returns: x >= y.

template<> struct greater_equal<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) >= std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) >= std::forward<U>(u));

    Returns: std::forward<T>(t) >= std::forward<U>(u).

```

22.10.8.7 Class template less_equal

[comparisons.less.equal]

```

template<class T = void> struct less_equal {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

    Returns: x <= y.

template<> struct less_equal<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) <= std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) <= std::forward<U>(u));

    Returns: std::forward<T>(t) <= std::forward<U>(u).

```

22.10.8.8 Class compare_three_way

[comparisons.three.way]

```

namespace std {
    struct compare_three_way {
        template<class T, class U>
            constexpr auto operator()(T&& t, U&& u) const;

        using is_transparent = unspecified;
    };
}

```

```

template<class T, class U>
    constexpr auto operator()(T&& t, U&& u) const;

```

Constraints: T and U satisfy `three_way_comparable_with`.

Preconditions: If the expression `std::forward<T>(t) <=> std::forward<U>(u)` results in a call to a built-in operator `<=>` comparing pointers of type P, the conversion sequences from both T and U to P are equality-preserving (18.2); otherwise, T and U model `three_way_comparable_with`.

Effects:

- If the expression `std::forward<T>(t) <=> std::forward<U>(u)` results in a call to a built-in operator `<=>` comparing pointers of type P, returns `strong_ordering::less` if (the converted value of) `t` precedes `u` in the implementation-defined strict total order over pointers (3.26), `strong_ordering::greater` if `u` precedes `t`, and otherwise `strong_ordering::equal`.
- Otherwise, equivalent to: `return std::forward<T>(t) <=> std::forward<U>(u);`

22.10.9 Concept-constrained comparisons

[range.cmp]

```
struct ranges::equal_to {
    template<class T, class U>
        constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
};
```

```
template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

    Constraints: T and U satisfy equality_comparable_with.
```

Preconditions: If the expression `std::forward<T>(t) == std::forward<U>(u)` results in a call to a built-in operator `==` comparing pointers of type P, the conversion sequences from both T and U to P are equality-preserving (18.2); otherwise, T and U model `equality_comparable_with`.

Effects:

- If the expression `std::forward<T>(t) == std::forward<U>(u)` results in a call to a built-in operator `==` comparing pointers: returns `false` if either (the converted value of) `t` precedes `u` or `u` precedes `t` in the implementation-defined strict total order over pointers (3.26) and otherwise `true`.
- Otherwise, equivalent to: `return std::forward<T>(t) == std::forward<U>(u);`

```
struct ranges::not_equal_to {
    template<class T, class U>
        constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
};
```

```
template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

    Constraints: T and U satisfy equality_comparable_with.
```

Effects: Equivalent to:

```
return !ranges::equal_to{}(std::forward<T>(t), std::forward<U>(u));
```

```
struct ranges::greater {
    template<class T, class U>
        constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
};
```

```
template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

    Constraints: T and U satisfy totally_ordered_with.
```

Effects: Equivalent to:

```
return ranges::less{}(std::forward<U>(u), std::forward<T>(t));
```

```
struct ranges::less {
    template<class T, class U>
        constexpr bool operator()(T&& t, U&& u) const;
```

```

    using is_transparent = unspecified;
};

template<class T, class U>
constexpr bool operator()(T&& t, U&& u) const;

    Constraints: T and U satisfy totally_ordered_with.

    Preconditions: If the expression std::forward<T>(t) < std::forward<U>(u) results in a call to a
    built-in operator < comparing pointers of type P, the conversion sequences from both T and U to P are
    equality-preserving (18.2); otherwise, T and U model totally_ordered_with. For any expressions ET
    and EU such that decltype((ET)) is T and decltype((EU)) is U, exactly one of ranges::less{ }(ET,
    EU), ranges::less{ }(EU, ET), or ranges::equal_to{ }(ET, EU) is true.

    Effects:
    — If the expression std::forward<T>(t) < std::forward<U>(u) results in a call to a built-in
    operator < comparing pointers: returns true if (the converted value of) t precedes u in the
    implementation-defined strict total order over pointers (3.26) and otherwise false.
    — Otherwise, equivalent to: return std::forward<T>(t) < std::forward<U>(u);

    struct ranges::greater_equal {
    template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
};

template<class T, class U>
constexpr bool operator()(T&& t, U&& u) const;

    Constraints: T and U satisfy totally_ordered_with.

    Effects: Equivalent to:
        return !ranges::less{ }(std::forward<T>(t), std::forward<U>(u));

    struct ranges::less_equal {
    template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
};

template<class T, class U>
constexpr bool operator()(T&& t, U&& u) const;

    Constraints: T and U satisfy totally_ordered_with.

    Effects: Equivalent to:
        return !ranges::less{ }(std::forward<U>(u), std::forward<T>(t));

```

22.10.10 Logical operations

[logical.operations]

22.10.10.1 General

[logical.operations.general]

The library provides basic function object classes for all of the logical operators in the language (7.6.14, 7.6.15, 7.6.2.2).

22.10.10.2 Class template logical_and

[logical.operations.and]

```

template<class T = void> struct logical_and {
    constexpr bool operator()(const T& x, const T& y) const;
};

```

```
constexpr bool operator()(const T& x, const T& y) const;
```

Returns: x && y.

```
template<> struct logical_and<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) && std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) && std::forward<U>(u));

Returns: std::forward<T>(t) && std::forward<U>(u).
```

22.10.10.3 Class template `logical_or`

[logical.operations.or]

```
template<class T = void> struct logical_or {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

Returns: x || y.

template<> struct logical_or<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) || std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) || std::forward<U>(u));

Returns: std::forward<T>(t) || std::forward<U>(u).
```

22.10.10.4 Class template `logical_not`

[logical.operations.not]

```
template<class T = void> struct logical_not {
    constexpr bool operator()(const T& x) const;
};

constexpr bool operator()(const T& x) const;

Returns: !x.

template<> struct logical_not<void> {
    template<class T> constexpr auto operator()(T&& t) const
        -> decltype(!std::forward<T>(t));

    using is_transparent = unspecified;
};

template<class T> constexpr auto operator()(T&& t) const
    -> decltype(!std::forward<T>(t));

Returns: !std::forward<T>(t).
```

22.10.11 Bitwise operations

[bitwise.operations]

22.10.11.1 General

[bitwise.operations.general]

The library provides basic function object classes for all of the bitwise operators in the language (7.6.11, 7.6.13, 7.6.12, 7.6.2.2).

22.10.11.2 Class template `bit_and`

[bitwise.operations.and]

```
template<class T = void> struct bit_and {
    constexpr T operator()(const T& x, const T& y) const;
};
```

```
constexpr T operator()(const T& x, const T& y) const;
```

Returns: $x \& y$.

```
template<> struct bit_and<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) & std::forward<U>(u));
```

```
    using is_transparent = unspecified;
};
```

```
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) & std::forward<U>(u));
```

Returns: $\text{std::forward<T>(t)} \& \text{std::forward<U>(u)}$.

22.10.11.3 Class template bit_or

[bitwise.operations.or]

```
template<class T = void> struct bit_or {
    constexpr T operator()(const T& x, const T& y) const;
};
```

```
constexpr T operator()(const T& x, const T& y) const;
```

Returns: $x \mid y$.

```
template<> struct bit_or<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) | std::forward<U>(u));
```

```
    using is_transparent = unspecified;
};
```

```
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) | std::forward<U>(u));
```

Returns: $\text{std::forward<T>(t)} \mid \text{std::forward<U>(u)}$.

22.10.11.4 Class template bit_xor

[bitwise.operations.xor]

```
template<class T = void> struct bit_xor {
    constexpr T operator()(const T& x, const T& y) const;
};
```

```
constexpr T operator()(const T& x, const T& y) const;
```

Returns: $x \wedge y$.

```
template<> struct bit_xor<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) ^ std::forward<U>(u));
```

```
    using is_transparent = unspecified;
};
```

```
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) ^ std::forward<U>(u));
```

Returns: $\text{std::forward<T>(t)} \wedge \text{std::forward<U>(u)}$.

22.10.11.5 Class template bit_not

[bitwise.operations.not]

```
template<class T = void> struct bit_not {
    constexpr T operator()(const T& x) const;
};
```

```
constexpr T operator()(const T& x) const;
```

Returns: $\sim x$.

```
template<> struct bit_not<void> {
    template<class T> constexpr auto operator()(T&& t) const
        -> decltype(~std::forward<T>(t));
```

```
    using is_transparent = unspecified;
};
```

```
template<class T> constexpr auto operator()(T&& t) const
    -> decltype(~std::forward<T>(t));
```

Returns: ~std::forward<T>(t).

22.10.12 Class identity

[func.identity]

```
struct identity {
    template<class T>
        constexpr T&& operator()(T&& t) const noexcept;
```

```
    using is_transparent = unspecified;
};
```

```
template<class T>
    constexpr T&& operator()(T&& t) const noexcept;
```

Effects: Equivalent to: return std::forward<T>(t);

22.10.13 Function template not_fn

[func.not.fn]

```
template<class F> constexpr unspecified not_fn(F&& f);
```

In the text that follows:

- g is a value of the result of a not_fn invocation,
- FD is the type decay_t<F>,
- fd is the target object of g (22.10.3) of type FD, direct-non-list-initialized with std::forward<F>(f),
- call_args is an argument pack used in a function call expression (7.6.1.3) of g.

Mandates: is_constructible_v<FD, F> && is_move_constructible_v<FD> is true.

Preconditions: FD meets the Cpp17MoveConstructible requirements.

Returns: A perfect forwarding call wrapper (22.10.4) g with call pattern !invoke(fd, call_args...).

Throws: Any exception thrown by the initialization of fd.

22.10.14 Function templates bind_front and bind_back

[func.bind.partial]

```
template<class F, class... Args>
    constexpr unspecified bind_front(F&& f, Args&&... args);
```

```
template<class F, class... Args>
    constexpr unspecified bind_back(F&& f, Args&&... args);
```

Within this subclause:

- g is a value of the result of a bind_front or bind_back invocation,
- FD is the type decay_t<F>,
- fd is the target object of g (22.10.3) of type FD, direct-non-list-initialized with std::forward<F>(f),
- BoundArgs is a pack that denotes decay_t<Args>...,
- bound_args is a pack of bound argument entities of g (22.10.3) of types BoundArgs..., direct-non-list-initialized with std::forward<Args>(args)..., respectively, and
- call_args is an argument pack used in a function call expression (7.6.1.3) of g.

Mandates:

```
is_constructible_v<FD, F> &&
is_move_constructible_v<FD> &&
(is_constructible_v<BoundArgs, Args> && ...) &&
(is_move_constructible_v<BoundArgs> && ...)
```

is true.

Preconditions: FD meets the *Cpp17MoveConstructible* requirements. For each T_i in BoundArgs, if T_i is an object type, T_i meets the *Cpp17MoveConstructible* requirements.

Returns: A perfect forwarding call wrapper (22.10.4) *g* with call pattern:

- `invoke(fd, bound_args..., call_args...)` for a `bind_front` invocation, or
- `invoke(fd, call_args..., bound_args...)` for a `bind_back` invocation.

Throws: Any exception thrown by the initialization of the state entities of *g* (22.10.3).

22.10.15 Function object binders

[func.bind]

22.10.15.1 General

[func.bind.general]

Subclause 22.10.15 describes a uniform mechanism for binding arguments of callable objects.

22.10.15.2 Class template `is_bind_expression`

[func.bind.isbind]

```
namespace std {
    template<class T> struct is_bind_expression; // see below
}
```

The class template `is_bind_expression` can be used to detect function objects generated by `bind`. The function template `bind` uses `is_bind_expression` to detect subexpressions.

Specializations of the `is_bind_expression` template shall meet the *Cpp17UnaryTypeTrait* requirements (21.3.2). The implementation provides a definition that has a base characteristic of `true_type` if *T* is a type returned from `bind`, otherwise it has a base characteristic of `false_type`. A program may specialize this template for a program-defined type *T* to have a base characteristic of `true_type` to indicate that *T* should be treated as a subexpression in a `bind` call.

22.10.15.3 Class template `is_placeholder`

[func.bind.isplace]

```
namespace std {
    template<class T> struct is_placeholder; // see below
}
```

The class template `is_placeholder` can be used to detect the standard placeholders `_1`, `_2`, and so on (22.10.15.5). The function template `bind` uses `is_placeholder` to detect placeholders.

Specializations of the `is_placeholder` template shall meet the *Cpp17UnaryTypeTrait* requirements (21.3.2). The implementation provides a definition that has the base characteristic of `integral_constant<int, J>` if *T* is the type of `std::placeholders::_J`, otherwise it has a base characteristic of `integral_constant<int, 0>`. A program may specialize this template for a program-defined type *T* to have a base characteristic of `integral_constant<int, N>` with $N > 0$ to indicate that *T* should be treated as a placeholder type.

22.10.15.4 Function template `bind`

[func.bind.bind]

In the text that follows:

- *g* is a value of the result of a `bind` invocation,
- FD is the type `decay_t<F>`,
- *fd* is an lvalue that is a target object of *g* (22.10.3) of type FD direct-non-list-initialized with `std::forward<F>(f)`,
- T_i is the i^{th} type in the template parameter pack BoundArgs,
- TD_i is the type `decay_t<T_i>`,
- t_i is the i^{th} argument in the function parameter pack bound_args,
- td_i is a bound argument entity of *g* (22.10.3) of type TD_i direct-non-list-initialized with `std::forward<T_i>(t_i)`,

- U_j is the j^{th} deduced type of the `UnBoundArgs&&...` parameter of the argument forwarding call wrapper, and
- u_j is the j^{th} argument associated with U_j .

```
template<class F, class... BoundArgs>
constexpr unspecified bind(F&& f, BoundArgs&&... bound_args);
template<class R, class F, class... BoundArgs>
constexpr unspecified bind(F&& f, BoundArgs&&... bound_args);
```

Mandates: `is_constructible_v<FD, F>` is true. For each T_i in `BoundArgs`, `is_constructible_v<TDi, Ti>` is true.

Preconditions: `FD` and each `TDi` meet the *Cpp17MoveConstructible* and *Cpp17Destructible* requirements. `INVOKE(fd, w1, w2, ..., wN)` (22.10.4) is a valid expression for some values `w1, w2, ..., wN`, where N has the value `sizeof...(bound_args)`.

Returns: An argument forwarding call wrapper `g` (22.10.4). A program that attempts to invoke a volatile-qualified `g` is ill-formed. When `g` is not volatile-qualified, invocation of `g(u1, u2, ..., uM)` is expression-equivalent (3.20) to

```
INVOKE(static_cast<Vfd>(vfd),
       static_cast<V1>(v1), static_cast<V2>(v2), ..., static_cast<VN>(vN))
```

for the first overload, and

```
INVOKE<R>(static_cast<Vfd>(vfd),
         static_cast<V1>(v1), static_cast<V2>(v2), ..., static_cast<VN>(vN))
```

for the second overload, where the values and types of the target argument `vfd` and of the bound arguments `v1, v2, ..., vN` are determined as specified below.

Throws: Any exception thrown by the initialization of the state entities of `g`.

NOTE If all of `FD` and `TDi` meet the requirements of *Cpp17CopyConstructible*, then the return type meets the requirements of *Cpp17CopyConstructible*.

The values of the *bound arguments* `v1, v2, ..., vN` and their corresponding types `V1, V2, ..., VN` depend on the types `TDi` derived from the call to `bind` and the cv-qualifiers `cv` of the call wrapper `g` as follows:

- if `TDi` is `reference_wrapper<T>`, the argument is `tdi.get()` and its type `Vi` is `T&`;
- if the value of `is_bind_expression_v<TDi>` is true, the argument is `static_cast<cv TDi&&>(tdi)(std::forward<Uj>(uj)...)` and its type `Vi` is `invoke_result_t<cv TDi&, Uj...>&&`;
- if the value `j` of `is_placeholder_v<TDi>` is not zero, the argument is `std::forward<Uj>(uj)` and its type `Vi` is `Uj&&`;
- otherwise, the value is `tdi` and its type `Vi` is `cv TDi&`.

The value of the target argument `vfd` is `fd` and its corresponding type `Vfd` is `cv FD&`.

22.10.15.5 Placeholders

[func.bind.place]

```
namespace std::placeholders {
    // M is the number of placeholders
    see below _1;
    see below _2;
    .
    .
    .
    see below _M;
}
```

The number M of placeholders is implementation-defined.

All placeholder types meet the *Cpp17DefaultConstructible* and *Cpp17CopyConstructible* requirements, and their default constructors and copy/move constructors are constexpr functions that do not throw exceptions. It is implementation-defined whether placeholder types meet the *Cpp17CopyAssignable* requirements, but if so, their copy assignment operators are constexpr functions that do not throw exceptions.

Placeholders should be defined as:

```
inline constexpr unspecified _1{};
```

If they are not, they are declared as:

```
extern unspecified _1;
```

Placeholders are freestanding items (16.3.3.6).

22.10.16 Function template `mem_fn`

[func.memfn]

```
template<class R, class T> constexpr unspecified mem_fn(R T::* pm) noexcept;
```

Returns: A simple call wrapper (22.10.4) `fn` with call pattern `invoke(pmd, call_args...)`, where `pmd` is the target object of `fn` of type `R T::*` direct-non-list-initialized with `pm`, and `call_args` is an argument pack used in a function call expression (7.6.1.3) of `fn`.

22.10.17 Polymorphic function wrappers

[func.wrap]

22.10.17.1 General

[func.wrap.general]

Subclause 22.10.17 describes polymorphic wrapper classes that encapsulate arbitrary callable objects.

22.10.17.2 Class `bad_function_call`

[func.wrap.badcall]

An exception of type `bad_function_call` is thrown by `function::operator()` (22.10.17.3.5) when the function wrapper object has no target.

```
namespace std {
    class bad_function_call : public exception {
    public:
        // see 17.9.3 for the specification of the special member functions
        const char* what() const noexcept override;
    };
}
```

```
const char* what() const noexcept override;
```

Returns: An implementation-defined NTBS.

22.10.17.3 Class template function

[func.wrap.func]

22.10.17.3.1 General

[func.wrap.func.general]

```
namespace std {
    template<class> class function; // not defined

    template<class R, class... ArgTypes>
    class function<R(ArgTypes...)> {
    public:
        using result_type = R;

        // 22.10.17.3.2, construct/copy/destroy
        function() noexcept;
        function(nullptr_t) noexcept;
        function(const function&);
        function(function&&) noexcept;
        template<class F> function(F&&);

        function& operator=(const function&);
        function& operator=(function&&);
        function& operator=(nullptr_t) noexcept;
        template<class F> function& operator=(F&&);
        template<class F> function& operator=(reference_wrapper<F>) noexcept;

        ~function();

        // 22.10.17.3.3, function modifiers
        void swap(function&) noexcept;

        // 22.10.17.3.4, function capacity
        explicit operator bool() const noexcept;
```

```

// 22.10.17.3.5, function invocation
R operator()(ArgTypes...) const;

// 22.10.17.3.6, function target access
const type_info& target_type() const noexcept;
template<class T> T* target() noexcept;
template<class T> const T* target() const noexcept;
};

template<class R, class... ArgTypes>
function(R*)(ArgTypes...) -> function<R(ArgTypes...)>;

template<class F> function(F) -> function<see below>;
}

```

The `function` class template provides polymorphic wrappers that generalize the notion of a function pointer. Wrappers can store, copy, and call arbitrary callable objects (22.10.3), given a call signature (22.10.3).

A callable type (22.10.3) `F` is *Lvalue-Callable* for argument types `ArgTypes` and return type `R` if the expression `INVOKE<R>(declval<F&>(), declval<ArgTypes>()...)`, considered as an unevaluated operand (7.2.3), is well-formed (22.10.4).

The `function` class template is a call wrapper (22.10.3) whose call signature (22.10.3) is `R(ArgTypes...)`.

NOTE The types deduced by the deduction guides for `function` are not guaranteed to remain unchanged in future revisions of this document.

22.10.17.3.2 Constructors and destructor

[func.wrap.func.con]

```
function() noexcept;
```

Postconditions: `!*this`.

```
function(nullptr_t) noexcept;
```

Postconditions: `!*this`.

```
function(const function& f);
```

Postconditions: `!*this` if `!f`; otherwise, the target object of `*this` is a copy of `f.target()`.

Throws: Nothing if `f`'s target is a specialization of `reference_wrapper` or a function pointer. Otherwise, may throw `bad_alloc` or any exception thrown by the copy constructor of the stored callable object.

Recommended practice: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where `f`'s target is an object holding only a pointer or reference to an object and a member function pointer.

```
function(function&& f) noexcept;
```

Postconditions: If `!f`, `*this` has no target; otherwise, the target of `*this` is equivalent to the target of `f` before the construction, and `f` is in a valid state with an unspecified value.

Recommended practice: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where `f`'s target is an object holding only a pointer or reference to an object and a member function pointer.

```
template<class F> function(F&& f);
```

Let `FD` be `decay_t<F>`.

Constraints:

- `is_same_v<remove_cvref_t<F>, function>` is false, and
- `FD` is *Lvalue-Callable* (22.10.17.3) for argument types `ArgTypes...` and return type `R`.

Mandates:

- `is_copy_constructible_v<FD>` is true, and
- `is_constructible_v<FD, F>` is true.

Preconditions: FD meets the *Cpp17CopyConstructible* requirements.

Postconditions: `!*this` is true if any of the following hold:

- `f` is a null function pointer value.
- `f` is a null member pointer value.
- `remove_cvref_t<F>` is a specialization of the function class template, and `!f` is true.

Otherwise, `*this` has a target object of type FD direct-non-list-initialized with `std::forward<F>(f)`.

Throws: Nothing if FD is a specialization of `reference_wrapper` or a function pointer type. Otherwise, may throw `bad_alloc` or any exception thrown by the initialization of the target object.

Recommended practice: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where `f` refers to an object holding only a pointer or reference to an object and a member function pointer.

```
template<class F> function(F) -> function<see below>;
```

Constraints: `&F::operator()` is well-formed when treated as an unevaluated operand and either

- `F::operator()` is a non-static member function and `decltype(&F::operator())` is either of the form `R(G::*)(A...) cv &opt noexceptopt` or of the form `R(*) (G, A...) noexceptopt` for a type `G`, or
- `F::operator()` is a static member function and `decltype(&F::operator())` is of the form `R(*) (A...) noexceptopt`.

Remarks: The deduced type is `function<R(A...)>`.

EXAMPLE

```
void f() {
    int i{5};
    function g = [&](double) { return i; }; // deduces function<int(double)>
}
```

```
function& operator=(const function& f);
```

Effects: As if by `function(f).swap(*this)`;

Returns: `*this`.

```
function& operator=(function&& f);
```

Effects: Replaces the target of `*this` with the target of `f`.

Returns: `*this`.

```
function& operator=(nullptr_t) noexcept;
```

Effects: If `*this != nullptr`, destroys the target of `this`.

Postconditions: `!(*this)`.

Returns: `*this`.

```
template<class F> function& operator=(F&& f);
```

Constraints: `decay_t<F>` is Lvalue-Callable (22.10.17.3) for argument types `ArgTypes...` and return type `R`.

Effects: As if by: `function(std::forward<F>(f)).swap(*this)`;

Returns: `*this`.

```
template<class F> function& operator=(reference_wrapper<F> f) noexcept;
```

Effects: As if by: `function(f).swap(*this)`;

Returns: `*this`.

```
~function();
```

Effects: If `*this != nullptr`, destroys the target of `this`.

22.10.17.3.3 Modifiers

[func.wrap.func.mod]

```
void swap(function& other) noexcept;
```

Effects: Interchanges the target objects of **this* and *other*.

22.10.17.3.4 Capacity

[func.wrap.func.cap]

```
explicit operator bool() const noexcept;
```

Returns: true if **this* has a target, otherwise false.

22.10.17.3.5 Invocation

[func.wrap.func.inv]

```
R operator()(ArgTypes... args) const;
```

Returns: *INVOKE*<R>(f, std::forward<ArgTypes>(args)...) (22.10.4), where *f* is the target object (22.10.3) of **this*.

Throws: *bad_function_call* if *!*this*; otherwise, any exception thrown by the target object.

22.10.17.3.6 Target access

[func.wrap.func.targ]

```
const type_info& target_type() const noexcept;
```

Returns: If **this* has a target of type *T*, *typeid(T)*; otherwise, *typeid(void)*.

```
template<class T> T* target() noexcept;
template<class T> const T* target() const noexcept;
```

Returns: If *target_type() == typeid(T)* a pointer to the stored function target; otherwise a null pointer.

22.10.17.3.7 Null pointer comparison operator functions

[func.wrap.func.nullptr]

```
template<class R, class... ArgTypes>
bool operator==(const function<R(ArgTypes...)>& f, nullptr_t) noexcept;
```

Returns: *!f*.

22.10.17.3.8 Specialized algorithms

[func.wrap.func.alg]

```
template<class R, class... ArgTypes>
void swap(function<R(ArgTypes...)>& f1, function<R(ArgTypes...)>& f2) noexcept;
```

Effects: As if by: *f1.swap(f2)*;

22.10.17.4 Move only wrapper

[func.wrap.move]

22.10.17.4.1 General

[func.wrap.move.general]

The header provides partial specializations of *move_only_function* for each combination of the possible replacements of the placeholders *cv*, *ref*, and *noex* where

- *cv* is either *const* or empty,
- *ref* is either *&*, *&&*, or empty, and
- *noex* is either *true* or *false*.

For each of the possible combinations of the placeholders mentioned above, there is a placeholder *inv-quals* defined as follows:

- If *ref* is empty, let *inv-quals* be *cv&*,
- otherwise, let *inv-quals* be *cv ref*.

22.10.17.4.2 Class template *move_only_function*

[func.wrap.move.class]

```
namespace std {
    template<class... S> class move_only_function; // not defined

    template<class R, class... ArgTypes>
    class move_only_function<R(ArgTypes...) cv ref noexcept(noex)> {
    public:
        using result_type = R;
```

```

// 22.10.17.4.3, constructors, assignment, and destructor
move_only_function() noexcept;
move_only_function(nullptr_t) noexcept;
move_only_function(move_only_function&&) noexcept;
template<class F> move_only_function(F&&);
template<class T, class... Args>
    explicit move_only_function(in_place_type_t<T>, Args&&...);
template<class T, class U, class... Args>
    explicit move_only_function(in_place_type_t<T>, initializer_list<U>, Args&&...);

move_only_function& operator=(move_only_function&&);
move_only_function& operator=(nullptr_t) noexcept;
template<class F> move_only_function& operator=(F&&);

~move_only_function();

// 22.10.17.4.4, invocation
explicit operator bool() const noexcept;
R operator()(ArgTypes...) cv ref noexcept(noex);

// 22.10.17.4.5, utility
void swap(move_only_function&) noexcept;
friend void swap(move_only_function&, move_only_function&) noexcept;
friend bool operator==(const move_only_function&, nullptr_t) noexcept;

private:
    template<class VT>
        static constexpr bool is-callable-from = see below; // exposition only
};
}

```

The `move_only_function` class template provides polymorphic wrappers that generalize the notion of a callable object (22.10.3). These wrappers can store, move, and call arbitrary callable objects, given a call signature.

Recommended practice: Implementations should avoid the use of dynamically allocated memory for a small contained value.

NOTE Such small-object optimization can only be applied to a type `T` for which `is_nothrow_move_constructible_v<T>` is true.

22.10.17.4.3 Constructors, assignment, and destructor

[func.wrap.move.ctor]

```

template<class VT>
    static constexpr bool is-callable-from = see below;

    If noex is true, is-callable-from<VT> is equal to:

        is_nothrow_invocable_r_v<R, VT cv ref, ArgTypes...> &&
        is_nothrow_invocable_r_v<R, VT inv-quals, ArgTypes...>

    Otherwise, is-callable-from<VT> is equal to:

        is_invocable_r_v<R, VT cv ref, ArgTypes...> &&
        is_invocable_r_v<R, VT inv-quals, ArgTypes...>

```

```

move_only_function() noexcept;
move_only_function(nullptr_t) noexcept;

```

Postconditions: `*this` has no target object.

```

move_only_function(move_only_function&& f) noexcept;

```

Postconditions: The target object of `*this` is the target object `f` had before construction, and `f` is in a valid state with an unspecified value.

```

template<class F> move_only_function(F&& f);

```

Let `VT` be `decay_t<F>`.

Constraints:

- `remove_cvref_t<F>` is not the same type as `move_only_function`, and
- `remove_cvref_t<F>` is not a specialization of `in_place_type_t`, and
- `is-callable-from<VT>` is true.

Mandates: `is_constructible_v<VT, F>` is true.

Preconditions: VT meets the *Cpp17Destructible* requirements, and if `is_move_constructible_v<VT>` is true, VT meets the *Cpp17MoveConstructible* requirements.

Postconditions: `*this` has no target object if any of the following hold:

- `f` is a null function pointer value, or
- `f` is a null member pointer value, or
- `remove_cvref_t<F>` is a specialization of the `move_only_function` class template, and `f` has no target object.

Otherwise, `*this` has a target object of type VT direct-non-list-initialized with `std::forward<F>(f)`.

Throws: Any exception thrown by the initialization of the target object. May throw `bad_alloc` unless VT is a function pointer or a specialization of `reference_wrapper`.

```
template<class T, class... Args>
explicit move_only_function(in_place_type_t<T>, Args&&... args);
```

Let VT be `decay_t<T>`.

Constraints:

- `is_constructible_v<VT, Args...>` is true, and
- `is-callable-from<VT>` is true.

Mandates: VT is the same type as T.

Preconditions: VT meets the *Cpp17Destructible* requirements, and if `is_move_constructible_v<VT>` is true, VT meets the *Cpp17MoveConstructible* requirements.

Postconditions: `*this` has a target object of type VT direct-non-list-initialized with `std::forward<Args>(args)...`

Throws: Any exception thrown by the initialization of the target object. May throw `bad_alloc` unless VT is a function pointer or a specialization of `reference_wrapper`.

```
template<class T, class U, class... Args>
explicit move_only_function(in_place_type_t<T>, initializer_list<U> ilist, Args&&... args);
```

Let VT be `decay_t<T>`.

Constraints:

- `is_constructible_v<VT, initializer_list<U>&, Args...>` is true, and
- `is-callable-from<VT>` is true.

Mandates: VT is the same type as T.

Preconditions: VT meets the *Cpp17Destructible* requirements, and if `is_move_constructible_v<VT>` is true, VT meets the *Cpp17MoveConstructible* requirements.

Postconditions: `*this` has a target object of type VT direct-non-list-initialized with `ilist, std::forward<Args>(args)...`

Throws: Any exception thrown by the initialization of the target object. May throw `bad_alloc` unless VT is a function pointer or a specialization of `reference_wrapper`.

```
move_only_function& operator=(move_only_function&& f);
```

Effects: Equivalent to: `move_only_function(std::move(f)).swap(*this);`

Returns: `*this`.

```
move_only_function& operator=(nullptr_t) noexcept;
```

Effects: Destroys the target object of **this*, if any.

Returns: **this*.

```
template<class F> move_only_function& operator=(F&& f);
```

Effects: Equivalent to: `move_only_function(std::forward<F>(f)).swap(*this);`

Returns: **this*.

```
~move_only_function();
```

Effects: Destroys the target object of **this*, if any.

22.10.17.4.4 Invocation

[func.wrap.move.inv]

```
explicit operator bool() const noexcept;
```

Returns: true if **this* has a target object, otherwise false.

```
R operator()(ArgTypes... args) cv ref noexcept(noex);
```

Preconditions: **this* has a target object.

Effects: Equivalent to:

```
return INVOKE<R>(static_cast<F inv-quals>(f), std::forward<ArgTypes>(args)...);
```

where *f* is an lvalue designating the target object of **this* and *F* is the type of *f*.

22.10.17.4.5 Utility

[func.wrap.move.util]

```
void swap(move_only_function& other) noexcept;
```

Effects: Exchanges the target objects of **this* and *other*.

```
friend void swap(move_only_function& f1, move_only_function& f2) noexcept;
```

Effects: Equivalent to `f1.swap(f2)`.

```
friend bool operator==(const move_only_function& f, nullptr_t) noexcept;
```

Returns: true if *f* has no target object, otherwise false.

22.10.18 Searchers

[func.search]

22.10.18.1 General

[func.search.general]

Subclause 22.10.18 provides function object types (22.10) for operations that search for a sequence [*pat_first*, *pat_last*) in another sequence [*first*, *last*) that is provided to the object's function call operator. The first sequence (the pattern to be searched for) is provided to the object's constructor, and the second (the sequence to be searched) is provided to the function call operator.

Each specialization of a class template specified in 22.10.18 shall meet the *Cpp17CopyConstructible* and *Cpp17CopyAssignable* requirements. Template parameters named

- `ForwardIterator`,
- `ForwardIterator1`,
- `ForwardIterator2`,
- `RandomAccessIterator`,
- `RandomAccessIterator1`,
- `RandomAccessIterator2`, and
- `BinaryPredicate`

of templates specified in 22.10.18 shall meet the same requirements and semantics as specified in 27.1. Template parameters named `Hash` shall meet the *Cpp17Hash* requirements (Table 37).

The Boyer-Moore searcher implements the Boyer-Moore search algorithm. The Boyer-Moore-Horspool searcher implements the Boyer-Moore-Horspool search algorithm. In general, the Boyer-Moore searcher will use more memory and give better runtime performance than Boyer-Moore-Horspool.

22.10.18.2 Class template default_searcher

[func.search.default]

```

namespace std {
    template<class ForwardIterator1, class BinaryPredicate = equal_to<>>
    class default_searcher {
    public:
        constexpr default_searcher(ForwardIterator1 pat_first, ForwardIterator1 pat_last,
                                   BinaryPredicate pred = BinaryPredicate());

        template<class ForwardIterator2>
        constexpr pair<ForwardIterator2, ForwardIterator2>
        operator()(ForwardIterator2 first, ForwardIterator2 last) const;

    private:
        ForwardIterator1 pat_first_;           // exposition only
        ForwardIterator1 pat_last_;           // exposition only
        BinaryPredicate pred_;                // exposition only
    };
}

constexpr default_searcher(ForwardIterator1 pat_first, ForwardIterator1 pat_last,
                           BinaryPredicate pred = BinaryPredicate());

Effects: Constructs a default_searcher object, initializing pat_first_ with pat_first, pat_last_
with pat_last, and pred_ with pred.

Throws: Any exception thrown by the copy constructor of BinaryPredicate or ForwardIterator1.

template<class ForwardIterator2>
constexpr pair<ForwardIterator2, ForwardIterator2>
operator()(ForwardIterator2 first, ForwardIterator2 last) const;

Effects: Returns a pair of iterators i and j such that
— i == search(first, last, pat_first_, pat_last_, pred_), and
— if i == last, then j == last, otherwise j == next(i, distance(pat_first_, pat_last_)).

```

22.10.18.3 Class template boyer_moore_searcher

[func.search.bm]

```

namespace std {
    template<class RandomAccessIterator1,
             class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>,
             class BinaryPredicate = equal_to<>>
    class boyer_moore_searcher {
    public:
        boyer_moore_searcher(RandomAccessIterator1 pat_first,
                              RandomAccessIterator1 pat_last,
                              Hash hf = Hash(),
                              BinaryPredicate pred = BinaryPredicate());

        template<class RandomAccessIterator2>
        pair<RandomAccessIterator2, RandomAccessIterator2>
        operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

    private:
        RandomAccessIterator1 pat_first_;     // exposition only
        RandomAccessIterator1 pat_last_;     // exposition only
        Hash hash_;                          // exposition only
        BinaryPredicate pred_;               // exposition only
    };
}

boyer_moore_searcher(RandomAccessIterator1 pat_first,
                     RandomAccessIterator1 pat_last,
                     Hash hf = Hash(),

```

```
BinaryPredicate pred = BinaryPredicate();
```

Preconditions: The value type of `RandomAccessIterator1` meets the *Cpp17DefaultConstructible*, the *Cpp17CopyConstructible*, and the *Cpp17CopyAssignable* requirements.

Let `V` be `iterator_traits<RandomAccessIterator1>::value_type`. For any two values `A` and `B` of type `V`, if `pred(A, B) == true`, then `hf(A) == hf(B)` is true.

Effects: Initializes `pat_first_` with `pat_first`, `pat_last_` with `pat_last`, `hash_` with `hf`, and `pred_` with `pred`.

Throws: Any exception thrown by the copy constructor of `RandomAccessIterator1`, or by the default constructor, copy constructor, or the copy assignment operator of the value type of `RandomAccessIterator1`, or the copy constructor or `operator()` of `BinaryPredicate` or `Hash`. May throw `bad_alloc` if additional memory needed for internal data structures cannot be allocated.

```
template<class RandomAccessIterator2>
pair<RandomAccessIterator2, RandomAccessIterator2>
operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;
```

Mandates: `RandomAccessIterator1` and `RandomAccessIterator2` have the same value type.

Effects: Finds a subsequence of equal values in a sequence.

Returns: A pair of iterators `i` and `j` such that

- `i` is the first iterator in the range `[first, last - (pat_last_ - pat_first_))` such that for every non-negative integer `n` less than `pat_last_ - pat_first_` the following condition holds: `pred(*(i + n), *(pat_first_ + n)) != false`, and
- `j == next(i, distance(pat_first_, pat_last_))`.

Returns `make_pair(first, first)` if `[pat_first_, pat_last_)` is empty, otherwise returns `make_pair(last, last)` if no such iterator is found.

Complexity: At most $(last - first) * (pat\_last\_ - pat\_first\_)$ applications of the predicate.

22.10.18.4 Class template `boyer_moore_horspool_searcher` [func.search.bmh]

```
namespace std {
    template<class RandomAccessIterator1,
            class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>,
            class BinaryPredicate = equal_to<>>
    class boyer_moore_horspool_searcher {
    public:
        boyer_moore_horspool_searcher(RandomAccessIterator1 pat_first,
                                      RandomAccessIterator1 pat_last,
                                      Hash hf = Hash(),
                                      BinaryPredicate pred = BinaryPredicate());

        template<class RandomAccessIterator2>
        pair<RandomAccessIterator2, RandomAccessIterator2>
        operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

    private:
        RandomAccessIterator1 pat_first_; // exposition only
        RandomAccessIterator1 pat_last_;  // exposition only
        Hash hash_;                       // exposition only
        BinaryPredicate pred_;            // exposition only
    };
}
```

```
boyer_moore_horspool_searcher(RandomAccessIterator1 pat_first,
                              RandomAccessIterator1 pat_last,
                              Hash hf = Hash(),
                              BinaryPredicate pred = BinaryPredicate());
```

Preconditions: The value type of `RandomAccessIterator1` meets the *Cpp17DefaultConstructible*, *Cpp17CopyConstructible*, and *Cpp17CopyAssignable* requirements.

Let `V` be `iterator_traits<RandomAccessIterator1>::value_type`. For any two values `A` and `B` of type `V`, if `pred(A, B) == true`, then `hf(A) == hf(B)` is true.

Effects: Initializes `pat_first_` with `pat_first`, `pat_last_` with `pat_last`, `hash_` with `hf`, and `pred_` with `pred`.

Throws: Any exception thrown by the copy constructor of `RandomAccessIterator1`, or by the default constructor, copy constructor, or the copy assignment operator of the value type of `RandomAccessIterator1`, or the copy constructor or `operator()` of `BinaryPredicate` or `Hash`. May throw `bad_alloc` if additional memory needed for internal data structures cannot be allocated.

```
template<class RandomAccessIterator2>
pair<RandomAccessIterator2, RandomAccessIterator2>
operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;
```

Mandates: `RandomAccessIterator1` and `RandomAccessIterator2` have the same value type.

Effects: Finds a subsequence of equal values in a sequence.

Returns: A pair of iterators `i` and `j` such that

- `i` is the first iterator in the range `[first, last - (pat_last_ - pat_first_))` such that for every non-negative integer `n` less than `pat_last_ - pat_first_` the following condition holds: `pred(*(i + n), *(pat_first_ + n)) != false`, and
- `j == next(i, distance(pat_first_, pat_last_))`.

Returns `make_pair(first, first)` if `[pat_first_, pat_last_)` is empty, otherwise returns `make_pair(last, last)` if no such iterator is found.

Complexity: At most `(last - first) * (pat_last_ - pat_first_)` applications of the predicate.

22.10.19 Class template `hash`

[unord.hash]

The unordered associative containers defined in 24.5 use specializations of the class template `hash` (22.10.2) as the default hash function.

Each specialization of `hash` is either enabled or disabled, as described below.

NOTE 1 Enabled specializations meet the *Cpp17Hash* requirements, and disabled specializations do not.

Each header that declares the template `hash` provides enabled specializations of `hash` for `nullptr_t` and all cv-unqualified arithmetic, enumeration, and pointer types. For any type `Key` for which neither the library nor the user provides an explicit or partial specialization of the class template `hash`, `hash<Key>` is disabled.

If the library provides an explicit or partial specialization of `hash<Key>`, that specialization is enabled except as noted otherwise, and its member functions are `noexcept` except as noted otherwise.

If `H` is a disabled specialization of `hash`, these values are false: `is_default_constructible_v<H>`, `is_copy_constructible_v<H>`, `is_move_constructible_v<H>`, `is_copy_assignable_v<H>`, and `is_move_assignable_v<H>`. Disabled specializations of `hash` are not function object types (22.10).

NOTE 2 This means that the specialization of `hash` exists, but any attempts to use it as a *Cpp17Hash* will be ill-formed.

An enabled specialization `hash<Key>` will:

- meet the *Cpp17Hash* requirements (Table 37), with `Key` as the function call argument type, the *Cpp17DefaultConstructible* requirements (Table 30), the *Cpp17CopyAssignable* requirements (Table 34), the *Cpp17Swappable* requirements (16.4.4.3),
- meet the requirement that if `k1 == k2` is true, `h(k1) == h(k2)` is also true, where `h` is an object of type `hash<Key>` and `k1` and `k2` are objects of type `Key`;
- meet the requirement that the expression `h(k)`, where `h` is an object of type `hash<Key>` and `k` is an object of type `Key`, shall not throw an exception unless `hash<Key>` is a program-defined specialization.

22.11 Class `type_index`

[type.index]

22.11.1 Header `<typeindex>` synopsis

[type.index.synopsis]

```
#include <compare> // see 17.11.1

namespace std {
    class type_index;
```

```
template<class T> struct hash;
template<> struct hash<type_index>;
}
```

22.11.2 type_index overview

[type.index.overview]

```
namespace std {
    class type_index {
    public:
        type_index(const type_info& rhs) noexcept;
        bool operator==(const type_index& rhs) const noexcept;
        bool operator< (const type_index& rhs) const noexcept;
        bool operator> (const type_index& rhs) const noexcept;
        bool operator<=(const type_index& rhs) const noexcept;
        bool operator>=(const type_index& rhs) const noexcept;
        strong_ordering operator<=>(const type_index& rhs) const noexcept;
        size_t hash_code() const noexcept;
        const char* name() const noexcept;

    private:
        const type_info* target;    // exposition only
        // Note that the use of a pointer here, rather than a reference,
        // means that the default copy/move constructor and assignment
        // operators will be provided and work as expected.
    };
}
```

The class `type_index` provides a simple wrapper for `type_info` which can be used as an index type in associative containers (24.4) and in unordered associative containers (24.5).

22.11.3 type_index members

[type.index.members]

```
type_index(const type_info& rhs) noexcept;
```

Effects: Constructs a `type_index` object, the equivalent of `target = &rhs`.

```
bool operator==(const type_index& rhs) const noexcept;
```

Returns: `*target == *rhs.target`.

```
bool operator<(const type_index& rhs) const noexcept;
```

Returns: `target->before(*rhs.target)`.

```
bool operator>(const type_index& rhs) const noexcept;
```

Returns: `rhs.target->before(*target)`.

```
bool operator<=(const type_index& rhs) const noexcept;
```

Returns: `!rhs.target->before(*target)`.

```
bool operator>=(const type_index& rhs) const noexcept;
```

Returns: `!target->before(*rhs.target)`.

```
strong_ordering operator<=>(const type_index& rhs) const noexcept;
```

Effects: Equivalent to:

```
if (*target == *rhs.target) return strong_ordering::equal;
if (target->before(*rhs.target)) return strong_ordering::less;
return strong_ordering::greater;
```

```
size_t hash_code() const noexcept;
```

Returns: `target->hash_code()`.

```
const char* name() const noexcept;
```

Returns: `target->name()`.

22.11.4 Hash support

[type.index.hash]

```
template<> struct hash<type_index>;
```

For an object `index` of type `type_index`, `hash<type_index>()(index)` shall evaluate to the same result as `index.hash_code()`.

22.12 Execution policies

[execpol]

22.12.1 General

[execpol.general]

Subclause 22.12 describes classes that are *execution policy* types. An object of an execution policy type indicates the kinds of parallelism allowed in the execution of an algorithm and expresses the consequent requirements on the element access functions.

EXAMPLE

```
using namespace std;
vector<int> v = /* ... */;

// standard sequential sort
sort(v.begin(), v.end());

// explicitly sequential sort
sort(execution::seq, v.begin(), v.end());

// permitting parallel execution
sort(execution::par, v.begin(), v.end());

// permitting vectorization as well
sort(execution::par_unseq, v.begin(), v.end());
```

NOTE Implementations can provide additional execution policies to those described in this document as extensions to address parallel architectures that require idiosyncratic parameters for efficient execution.

22.12.2 Header <execution> synopsis

[execution.syn]

```
namespace std {
    // 22.12.3, execution policy type trait
    template<class T> struct is_execution_policy;
    template<class T> constexpr bool is_execution_policy_v = is_execution_policy<T>::value;
}

namespace std::execution {
    // 22.12.4, sequenced execution policy
    class sequenced_policy;

    // 22.12.5, parallel execution policy
    class parallel_policy;

    // 22.12.6, parallel and unsequenced execution policy
    class parallel_unsequenced_policy;

    // 22.12.7, unsequenced execution policy
    class unsequenced_policy;

    // 22.12.8, execution policy objects
    inline constexpr sequenced_policy      seq{ unspecified };
    inline constexpr parallel_policy        par{ unspecified };
    inline constexpr parallel_unsequenced_policy par_unseq{ unspecified };
    inline constexpr unsequenced_policy     unseq{ unspecified };
}
```

22.12.3 Execution policy type trait

[execpol.type]

```
template<class T> struct is_execution_policy { see below };
```

`is_execution_policy` can be used to detect execution policies for the purpose of excluding function signatures from otherwise ambiguous overload resolution participation.

`is_execution_policy<T>` is a *Cpp17UnaryTypeTrait* with a base characteristic of `true_type` if `T` is the type of a standard or implementation-defined execution policy, otherwise `false_type`.

NOTE This provision reserves the privilege of creating non-standard execution policies to the library implementation.

The behavior of a program that adds specializations for `is_execution_policy` is undefined.

22.12.4 Sequenced execution policy [execpol.seq]

```
class execution::sequenced_policy { unspecified };
```

The class `execution::sequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and require that a parallel algorithm's execution may not be parallelized.

During the execution of a parallel algorithm with the `execution::sequenced_policy` policy, if the invocation of an element access function exits via an exception, `terminate` is invoked (14.6.2).

22.12.5 Parallel execution policy [execpol.par]

```
class execution::parallel_policy { unspecified };
```

The class `execution::parallel_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be parallelized.

During the execution of a parallel algorithm with the `execution::parallel_policy` policy, if the invocation of an element access function exits via an exception, `terminate` is invoked (14.6.2).

22.12.6 Parallel and unsequenced execution policy [execpol.parunseq]

```
class execution::parallel_unsequenced_policy { unspecified };
```

The class `execution::parallel_unsequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be parallelized and vectorized.

During the execution of a parallel algorithm with the `execution::parallel_unsequenced_policy` policy, if the invocation of an element access function exits via an exception, `terminate` is invoked (14.6.2).

22.12.7 Unsequenced execution policy [execpol.unseq]

```
class execution::unsequenced_policy { unspecified };
```

The class `unsequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be vectorized, e.g., executed on a single thread using instructions that operate on multiple data items.

During the execution of a parallel algorithm with the `execution::unsequenced_policy` policy, if the invocation of an element access function exits via an exception, `terminate` is invoked (14.6.2).

22.12.8 Execution policy objects [execpol.objects]

```
inline constexpr execution::sequenced_policy      execution::seq{ unspecified };
inline constexpr execution::parallel_policy        execution::par{ unspecified };
inline constexpr execution::parallel_unsequenced_policy execution::par_unseq{ unspecified };
inline constexpr execution::unsequenced_policy     execution::unseq{ unspecified };
```

The header `<execution>` declares global objects associated with each type of execution policy.

22.13 Primitive numeric conversions [charconv]

22.13.1 Header `<charconv>` synopsis [charconv.syn]

When a function is specified with a type placeholder of *integer-type*, the implementation provides overloads for all cv-unqualified signed and unsigned integer types and `char` in lieu of *integer-type*. When a function is specified with a type placeholder of *floating-point-type*, the implementation provides overloads for all cv-unqualified floating-point types (6.8.2) in lieu of *floating-point-type*.

```

namespace std {
    // floating-point format for primitive numerical conversion
    enum class chars_format {
        scientific = unspecified,
        fixed = unspecified,
        hex = unspecified,
        general = fixed | scientific
    };

    // 22.13.2, primitive numerical output conversion
    struct to_chars_result {
        char* ptr;
        errc ec;
        friend bool operator==(const to_chars_result&, const to_chars_result&) = default;
    };

    constexpr to_chars_result to_chars(char* first, char* last, integer-type value, int base = 10);
    to_chars_result to_chars(char* first, char* last, bool value, int base = 10) = delete;

    to_chars_result to_chars(char* first, char* last, floating-point-type value);
    to_chars_result to_chars(char* first, char* last, floating-point-type value, chars_format fmt);
    to_chars_result to_chars(char* first, char* last, floating-point-type value,
        chars_format fmt, int precision);

    // 22.13.3, primitive numerical input conversion
    struct from_chars_result {
        const char* ptr;
        errc ec;
        friend bool operator==(const from_chars_result&, const from_chars_result&) = default;
    };

    constexpr from_chars_result from_chars(const char* first, const char* last,
        integer-type& value, int base = 10);

    from_chars_result from_chars(const char* first, const char* last, floating-point-type& value,
        chars_format fmt = chars_format::general);
}

```

The type `chars_format` is a bitmask type (16.3.3.3.3) with elements `scientific`, `fixed`, and `hex`.

The types `to_chars_result` and `from_chars_result` have the data members and special members specified above. They have no base classes or members other than those specified.

22.13.2 Primitive numeric output conversion

[charconv.to.chars]

All functions named `to_chars` convert `value` into a character string by successively filling the range `[first, last)`, where `(first, last)` is required to be a valid range. If the member `ec` of the return value is such that the value is equal to the value of a value-initialized `errc`, the conversion was successful and the member `ptr` is the one-past-the-end pointer of the characters written. Otherwise, the member `ec` has the value `errc::value_too_large`, the member `ptr` has the value `last`, and the contents of the range `[first, last)` are unspecified.

The functions that take a floating-point `value` but not a `precision` parameter ensure that the string representation consists of the smallest number of characters such that there is at least one digit before the radix point (if present) and parsing the representation using the corresponding `from_chars` function recovers `value` exactly.

NOTE This guarantee applies only if `to_chars` and `from_chars` are executed on the same implementation.

If there are several such representations, the representation with the smallest difference from the floating-point argument value is chosen, resolving any remaining ties using rounding according to `round_to_nearest` (17.3.4).

The functions taking a `chars_format` parameter determine the conversion specifier for `printf` as follows: The conversion specifier is `f` if `fmt` is `chars_format::fixed`, `e` if `fmt` is `chars_format::scientific`, `a` (without leading "0x" in the result) if `fmt` is `chars_format::hex`, and `g` if `fmt` is `chars_format::general`.

```
constexpr to_chars_result to_chars(char* first, char* last, integer-type value, int base = 10);
```

Preconditions: **base** has a value between 2 and 36 (inclusive).

Effects: The value of **value** is converted to a string of digits in the given base (with no redundant leading zeroes). Digits in the range 10..35 (inclusive) are represented as lowercase characters a..z. If **value** is less than zero, the representation starts with '-'.
Throws: Nothing.

```
to_chars_result to_chars(char* first, char* last, floating-point-type value);
```

Effects: **value** is converted to a string in the style of **printf** in the "C" locale. The conversion specifier is **f** or **e**, chosen according to the requirement for a shortest representation (see above); a tie is resolved in favor of **f**.
Throws: Nothing.

```
to_chars_result to_chars(char* first, char* last, floating-point-type value, chars_format fmt);
```

Preconditions: **fmt** has the value of one of the enumerators of **chars_format**.

Effects: **value** is converted to a string in the style of **printf** in the "C" locale.

Throws: Nothing.

```
to_chars_result to_chars(char* first, char* last, floating-point-type value,
                        chars_format fmt, int precision);
```

Preconditions: **fmt** has the value of one of the enumerators of **chars_format**.

Effects: **value** is converted to a string in the style of **printf** in the "C" locale with the given precision.

Throws: Nothing.

See also ISO/IEC 9899:2018, 7.21.6.1.

22.13.3 Primitive numeric input conversion [charconv.from.chars]

All functions named **from_chars** analyze the string **(first,last)** for a pattern, where **[first,last)** is required to be a valid range. If no characters match the pattern, **value** is unmodified, the member **ptr** of the return value is **first** and the member **ec** is equal to **errc::invalid_argument**.

NOTE If the pattern allows for an optional sign, but the string has no digit characters following the sign, no characters match the pattern.

Otherwise, the characters matching the pattern are interpreted as a representation of a value of the type of **value**. The member **ptr** of the return value points to the first character not matching the pattern, or has the value **last** if all characters match. If the parsed value is not in the range representable by the type of **value**, **value** is unmodified and the member **ec** of the return value is equal to **errc::result_out_of_range**. Otherwise, **value** is set to the parsed value, after rounding according to **round_to_nearest** (17.3.4), and the member **ec** is value-initialized.

```
constexpr from_chars_result from_chars(const char* first, const char* last,
                                     integer-type& value, int base = 10);
```

Preconditions: **base** has a value between 2 and 36 (inclusive).

Effects: The pattern is the expected form of the subject sequence in the "C" locale for the given nonzero **base**, as described for **strtoul**, except that no "0x" or "0X" prefix shall appear if the value of **base** is 16, and except that '-' is the only sign that may appear, and only if **value** has a signed type.

Throws: Nothing.

```
from_chars_result from_chars(const char* first, const char* last, floating-point-type& value,
                          chars_format fmt = chars_format::general);
```

Preconditions: **fmt** has the value of one of the enumerators of **chars_format**.

Effects: The pattern is the expected form of the subject sequence in the "C" locale, as described for **strtod**, except that

- the sign '+' may only appear in the exponent part;

- if `fmt` has `chars_format::scientific` set but not `chars_format::fixed`, the otherwise optional exponent part shall appear;
- if `fmt` has `chars_format::fixed` set but not `chars_format::scientific`, the optional exponent part shall not appear; and
- if `fmt` is `chars_format::hex`, the prefix "0x" or "0X" is assumed.

EXAMPLE The string 0x123 is parsed to have the value 0 with remaining characters x123.

In any case, the resulting value is one of at most two floating-point values closest to the value of the string matching the pattern.

Throws: Nothing.

See also ISO/IEC 9899:2018, 7.22.1.3, 7.22.1.4.

22.14 Formatting

22.14.1 Header `<format>` synopsis

[format]
[format.syn]

```
namespace std {
    // 22.14.6.6, class template basic_format_context

```

The class template `format_to_n_result` has the template parameters, data members, and special members specified above. It has no base classes or members other than those specified.

22.14.2 Format string

[format.string]

22.14.2.1 General

[format.string.general]

A *format string* for arguments `args` is a (possibly empty) sequence of *replacement fields*, *escape sequences*, and characters other than `{` and `}`. Let `charT` be the character type of the format string. Each character that is not part of a replacement field or an escape sequence is copied unchanged to the output. An escape sequence is one of `{ {` or `} }`. It is replaced with `{` or `}`, respectively, in the output. The syntax of replacement fields is as follows:

```

replacement-field:
    { arg-idopt format-specifieropt }

arg-id:
    0
    positive-integer

```

positive-integer:
 nonzero-digit
 positive-integer digit

nonnegative-integer:
 digit
 nonnegative-integer digit

nonzero-digit: one of
 1 2 3 4 5 6 7 8 9

digit: one of
 0 1 2 3 4 5 6 7 8 9

format-specifier:
 : *format-spec*

format-spec:
 as specified by the **formatter** specialization for the argument type

The *arg-id* field specifies the index of the argument in **args** whose value is to be formatted and inserted into the output instead of the replacement field. If there is no argument with the index *arg-id* in **args**, the string is not a format string for **args**. The optional *format-specifier* field explicitly specifies a format for the replacement value.

EXAMPLE 1

```
string s = format("{0}-{1}", 8);           // value of s is "8-{"
```

If all *arg-ids* in a format string are omitted (including those in the *format-spec*, as interpreted by the corresponding **formatter** specialization), argument indices 0, 1, 2, ... will automatically be used in that order. If some *arg-ids* are omitted and some are present, the string is not a format string.

NOTE It is not possible for a format string to contain a mixture of automatic and manual indexing.

EXAMPLE 2

```
string s0 = format("{} to {}", "a", "b"); // OK, automatic indexing
string s1 = format("{1} to {0}", "a", "b"); // OK, manual indexing
string s2 = format("{0} to {}", "a", "b"); // not a format string (mixing automatic and manual indexing),
                                           // ill-formed
string s3 = format("{} to {1}", "a", "b"); // not a format string (mixing automatic and manual indexing),
                                           // ill-formed
```

The *format-spec* field contains *format specifications* that define how the value should be presented. Each type can define its own interpretation of the *format-spec* field. If *format-spec* does not conform to the format specifications for the argument type referred to by *arg-id*, the string is not a format string for **args**.

EXAMPLE 3

- For arithmetic, pointer, and string types the *format-spec* is interpreted as a *std-format-spec* as described in (22.14.2.2).
- For chrono types the *format-spec* is interpreted as a *chrono-format-spec* as described in (29.12).
- For user-defined **formatter** specializations, the behavior of the **parse** member function determines how the *format-spec* is interpreted.

22.14.2.2 Standard format specifiers

[format.string.std]

Each **formatter** specialization described in 22.14.6.3 for fundamental and string types interprets *format-spec* as a *std-format-spec*.

NOTE 1 The format specification can be used to specify such details as minimum field width, alignment, padding, and decimal precision. Some of the formatting options are only supported for arithmetic types.

The syntax of format specifications is as follows:

std-format-spec:
 *fill-and-align*_{opt} *sign*_{opt} *#*_{opt} *0*_{opt} *width*_{opt} *precision*_{opt} *L*_{opt} *type*_{opt}

fill-and-align:
 *fill*_{opt} *align*

fill:
 any character other than { or }

align: one of
 < > ^

sign: one of
 + - space

width:
 positive-integer
 { *arg-id_{opt}* }

precision:
 nonnegative-integer
 { *arg-id_{opt}* }

type: one of
 a A b B c d e E f F g G o p s x X ?

Field widths are specified in *field width units*; the number of column positions required to display a sequence of characters in a terminal. The *minimum field width* is the number of field width units a replacement field minimally requires of the formatted sequence of characters produced for a format argument. The *estimated field width* is the number of field width units that are required for the formatted sequence of characters produced for a format argument independent of the effects of the *width* option. The *padding width* is the greater of 0 and the difference of the minimum field width and the estimated field width.

NOTE 2 The POSIX `wcswidth` function is an example of a function that, given a string, returns the number of column positions required by a terminal to display the string.

The *fill character* is the character denoted by the *fill* option or, if the *fill* option is absent, the space character. For a format specification in UTF-8, UTF-16, or UTF-32, the fill character corresponds to a single Unicode scalar value.

NOTE 3 The presence of a *fill* option is signaled by the character following it, which is one of the alignment options. If the second character of *std-format-spec* is not a valid alignment option, then it is assumed that the *fill* and *align* options are both absent.

The *align* option applies to all argument types. The meaning of the various alignment options is as specified in Table 65.

EXAMPLE 1

```
char c = 120;
string s0 = format("{:6}", 42);           // value of s0 is "  42"
string s1 = format("{:6}", 'x');           // value of s1 is "x   "
string s2 = format("{:*<6}", 'x');         // value of s2 is "x*****"
string s3 = format("{:*>6}", 'x');         // value of s3 is "*****x"
string s4 = format("{:*^6}", 'x');         // value of s4 is "***x***"
string s5 = format("{:6d}", c);            // value of s5 is "  120"
string s6 = format("{:6}", true);          // value of s6 is "true  "
string s7 = format("{:*6.3}", "123456");   // value of s7 is "123***"
string s8 = format("{:02}", 1234);         // value of s8 is "1234"
string s9 = format("{: *<}", "12");        // value of s9 is "12"
string sA = format("{:*<6}", "12345678"); // value of sA is "12345678"
string sB = format("{: 🤡^6}", "x");        // value of sB is "🤡🤡x🤡🤡🤡"
string sC = format("{: *<6}", "🤡🤡🤡");    // value of sC is "🤡🤡🤡"
```

NOTE 4 The *fill*, *align*, and 0 options have no effect when the minimum field width is not greater than the estimated field width because padding width is 0 in that case. Since fill characters are assumed to have a field width of 1, use of a character with a different field width can produce misaligned output. The 🤡 (U+1F921 CLOWN FACE) character has a field width of 2. The examples above that include that character illustrate the effect of the field width when that character is used as a fill character as opposed to when it is used as a formatting argument.

The *sign* option is only valid for arithmetic types other than `charT` and `bool` or when an integer presentation type is specified. The meaning of the various options is as specified in Table 66.

The *sign* option applies to floating-point infinity and NaN.

EXAMPLE 2

```
double inf = numeric_limits<double>::infinity();
double nan = numeric_limits<double>::quiet_NaN();
string s0 = format("{0:},{0:+},{0:-},{0: }", 1); // value of s0 is "1,+1,1, 1"
string s1 = format("{0:},{0:+},{0:-},{0: }", -1); // value of s1 is "-1,-1,-1,-1"
```

Table 65 — Meaning of *align* options [tab:format.align]

Option	Meaning
<	Forces the formatted argument to be aligned to the start of the field by inserting n fill characters after the formatted argument where n is the padding width. This is the default for non-arithmetic non-pointer types, <code>charT</code> , and <code>bool</code> , unless an integer presentation type is specified.
>	Forces the formatted argument to be aligned to the end of the field by inserting n fill characters before the formatted argument where n is the padding width. This is the default for arithmetic types other than <code>charT</code> and <code>bool</code> , pointer types, or when an integer presentation type is specified.
~	Forces the formatted argument to be centered within the field by inserting $\lceil \frac{n}{2} \rceil$ fill characters before and $\lfloor \frac{n}{2} \rfloor$ fill characters after the formatted argument, where n is the padding width.

Table 66 — Meaning of *sign* options [tab:format.sign]

Option	Meaning
+	Indicates that a sign should be used for both non-negative and negative numbers. The + sign is inserted before the output of <code>to_chars</code> for non-negative numbers other than negative zero. NOTE 5 For negative numbers and negative zero the output of <code>to_chars</code> will already contain the sign so no additional transformation is performed.
-	Indicates that a sign should be used for negative numbers and negative zero only (this is the default behavior).
space	Indicates that a leading space should be used for non-negative numbers other than negative zero, and a minus sign for negative numbers and negative zero.

```
string s2 = format("{0:},{0:+},{0:-},{0: }", inf);    // value of s2 is "inf,+inf,inf, inf"
string s3 = format("{0:},{0:+},{0:-},{0: }", nan);    // value of s3 is "nan,+nan,nan, nan"
```

The `#` option causes the *alternate form* to be used for the conversion. This option is valid for arithmetic types other than `charT` and `bool` or when an integer presentation type is specified, and not otherwise. For integral types, the alternate form inserts the base prefix (if any) specified in Table 68 into the output after the sign character (possibly space) if there is one, or before the output of `to_chars` otherwise. For floating-point types, the alternate form causes the result of the conversion of finite values to always contain a decimal-point character, even if no digits follow it. Normally, a decimal-point character appears in the result of these conversions only if a digit follows it. In addition, for `g` and `G` conversions, trailing zeros are not removed from the result.

The `0` option is valid for arithmetic types other than `charT` and `bool` or when an integer presentation type is specified. For formatting arguments that have a value other than an infinity or a NaN, this option pads the formatted argument by inserting the `0` character n times following the sign or base prefix indicators (if any) where n is 0 if the *align* option is present and is the padding width otherwise.

EXAMPLE 3

```
char c = 120;
string s1 = format("{:06d}", c);           // value of s1 is "+00120"
string s2 = format("{:#06x}", 0xa);        // value of s2 is "0x000a"
string s3 = format("{:<06}", -42);         // value of s3 is "-42" (0 has no effect)
string s4 = format("{:06}", inf);          // value of s4 is " inf" (0 has no effect)
```

The *width* option specifies the minimum field width. If the *width* option is absent, the minimum field width is 0.

If `{ arg-idopt }` is used in a *width* or *precision* option, the value of the corresponding formatting argument is used as the value of the option. If the corresponding formatting argument is not of standard signed or unsigned integer type, or its value is negative, an exception of type `format_error` is thrown.

If *positive-integer* is used in a *width* option, the value of the *positive-integer* is interpreted as a decimal integer and used as the value of the option.

For the purposes of width computation, a string is assumed to be in a locale-independent, implementation-defined encoding. Implementations should use either UTF-8, UTF-16, or UTF-32, on platforms capable of displaying Unicode text in a terminal.

NOTE 6 This is the case for Windows®-based²⁰⁴ and many POSIX-based operating systems.

For a sequence of characters in UTF-8, UTF-16, or UTF-32, an implementation should use as its field width the sum of the field widths of the first code point of each extended grapheme cluster. Extended grapheme clusters are defined by UAX #29 of the Unicode Standard. The following code points have a field width of 2:

- any code point with the `East_Asian_Width="W"` or `East_Asian_Width="F"` Derived Extracted Property as described by UAX #44 of the Unicode Standard
- U+4DC0 – U+4DFF (Yijing Hexagram Symbols)
- U+1F300 – U+1F5FF (Miscellaneous Symbols and Pictographs)
- U+1F900 – U+1F9FF (Supplemental Symbols and Pictographs)

The field width of all other code points is 1.

For a sequence of characters in neither UTF-8, UTF-16, nor UTF-32, the field width is unspecified.

The *precision* option is valid for floating-point and string types. For floating-point types, the value of this option specifies the precision to be used for the floating-point presentation type. For string types, this option specifies the longest prefix of the formatted argument to be included in the replacement field such that the field width of the prefix is no greater than the value of this option.

If *nonnegative-integer* is used in a *precision* option, the value of the decimal integer is used as the value of the option.

When the `L` option is used, the form used for the conversion is called the *locale-specific form*. The `L` option is only valid for arithmetic types, and its effect depends upon the type.

- For integral types, the locale-specific form causes the context's locale to be used to insert the appropriate digit group separator characters.
- For floating-point types, the locale-specific form causes the context's locale to be used to insert the appropriate digit group and radix separator characters.
- For the textual representation of `bool`, the locale-specific form causes the context's locale to be used to insert the appropriate string as if obtained with `numprint::true_name` or `numprint::false_name`.

The *type* determines how the data should be presented.

The available string presentation types are specified in Table 67.

Table 67 — Meaning of *type* options for strings [tab:format.type.string]

Type	Meaning
none, <code>s</code>	Copies the string to the output.
?	Copies the escaped string (22.14.6.4) to the output.

The meaning of some non-string presentation types is defined in terms of a call to `to_chars`. In such cases, let `[first, last)` be a range large enough to hold the `to_chars` output and `value` be the formatting argument value. Formatting is done as if by calling `to_chars` as specified and copying the output through the output iterator of the format context.

NOTE 7 Additional padding and adjustments are performed prior to copying the output through the output iterator as specified by the format specifiers.

The available integer presentation types for integral types other than `bool` and `charT` are specified in Table 68.

²⁰⁴) Windows® is a registered trademark of Microsoft Corporation. This information is given for the convenience of users of this document and does not constitute an endorsement by ISO or IEC of this product.

EXAMPLE 4

```

string s0 = format!("{}", 42);           // value of s0 is "42"
string s1 = format("{0:b} {0:d} {0:o} {0:x}", 42); // value of s1 is "101010 42 52 2a"
string s2 = format("{0:#x} {0:#X}", 42); // value of s2 is "0x2a 0X2A"
string s3 = format("{:L}", 1234);        // value of s3 can be "1,234"
                                           // (depending on the locale)

```

Table 68 — Meaning of *type* options for integer types [tab:format.type.int]

Type	Meaning
b	<code>to_chars(first, last, value, 2)</code> ; the base prefix is 0b.
B	The same as b, except that the base prefix is 0B.
c	Copies the character <code>static_cast<charT>(value)</code> to the output. Throws <code>format_error</code> if <code>value</code> is not in the range of representable values for <code>charT</code> .
d	<code>to_chars(first, last, value)</code> .
o	<code>to_chars(first, last, value, 8)</code> ; the base prefix is 0 if <code>value</code> is nonzero and is empty otherwise.
x	<code>to_chars(first, last, value, 16)</code> ; the base prefix is 0x.
X	The same as x, except that it uses uppercase letters for digits above 9 and the base prefix is 0X.
none	The same as d. NOTE 8 If the formatting argument type is <code>charT</code> or <code>bool</code> , the default is instead c or s, respectively.

The available `charT` presentation types are specified in Table 69.

Table 69 — Meaning of *type* options for `charT` [tab:format.type.char]

Type	Meaning
none, c	Copies the character to the output.
b, B, d, o, x, X	As specified in Table 68.
?	Copies the escaped character (22.14.6.4) to the output.

The available `bool` presentation types are specified in Table 70.

Table 70 — Meaning of *type* options for `bool` [tab:format.type.bool]

Type	Meaning
none, s	Copies textual representation, either <code>true</code> or <code>false</code> , to the output.
b, B, d, o, x, X	As specified in Table 68 for the value <code>static_cast<unsigned char>(value)</code> .

The available floating-point presentation types and their meanings for values other than infinity and NaN are specified in Table 71. For lower-case presentation types, infinity and NaN are formatted as `inf` and `nan`, respectively. For upper-case presentation types, infinity and NaN are formatted as `INF` and `NAN`, respectively.

NOTE 9 In either case, a sign is included if indicated by the *sign* option.

The available pointer presentation types and their mapping to `to_chars` are specified in Table 72.

NOTE 10 Pointer presentation types also apply to `nullptr_t`.

22.14.3 Error reporting

[format.err.report]

Formatting functions throw `format_error` if an argument `fmt` is passed that is not a format string for `args`. They propagate exceptions thrown by operations of `formatter` specializations and iterators. Failure to allocate storage is reported by throwing an exception as described in 16.4.6.13.

Table 71 — Meaning of *type* options for floating-point types [tab:format.type.float]

Type	Meaning
a	If <i>precision</i> is specified, equivalent to <code>to_chars(first, last, value, chars_format::hex, precision)</code> where <i>precision</i> is the specified formatting precision; equivalent to <code>to_chars(first, last, value, chars_format::hex)</code> otherwise.
A	The same as a , except that it uses uppercase letters for digits above 9 and P to indicate the exponent.
e	Equivalent to <code>to_chars(first, last, value, chars_format::scientific, precision)</code> where <i>precision</i> is the specified formatting precision, or 6 if <i>precision</i> is not specified.
E	The same as e , except that it uses E to indicate exponent.
f, F	Equivalent to <code>to_chars(first, last, value, chars_format::fixed, precision)</code> where <i>precision</i> is the specified formatting precision, or 6 if <i>precision</i> is not specified.
g	Equivalent to <code>to_chars(first, last, value, chars_format::general, precision)</code> where <i>precision</i> is the specified formatting precision, or 6 if <i>precision</i> is not specified.
G	The same as g , except that it uses E to indicate exponent.
none	If <i>precision</i> is specified, equivalent to <code>to_chars(first, last, value, chars_format::general, precision)</code> where <i>precision</i> is the specified formatting precision; equivalent to <code>to_chars(first, last, value)</code> otherwise.

Table 72 — Meaning of *type* options for pointer types [tab:format.type.ptr]

Type	Meaning
none, p	If <code>uintptr_t</code> is defined, <code>to_chars(first, last, reinterpret_cast<uintptr_t>(value), 16)</code> with the prefix 0x inserted immediately before the output of <code>to_chars</code> ; otherwise, implementation-defined.

22.14.4 Class template `basic_format_string`

[format.fmt.string]

```

namespace std {
    template<class charT, class... Args>
    struct basic_format_string {
    private:
        basic_string_view<charT> str;           // exposition only

    public:
        template<class T> consteval basic_format_string(const T& s);
        constexpr basic_string_view<charT> get() const noexcept { return str; }
    };
}

template<class T> consteval basic_format_string(const T& s);

```

Constraints: `const T&` models `convertible_to<basic_string_view<charT>>`.

Effects: Direct-non-list-initializes *str* with *s*.

Remarks: A call to this function is not a core constant expression (7.7) unless there exist *args* of types *Args* such that *str* is a format string for *args*.

22.14.5 Formatting functions

[format.functions]

In the description of the functions, operator + is used for some of the iterator categories for which it does not have to be defined. In these cases the semantics of `a + n` are the same as in 27.2.

```
template<class... Args>
string format(format_string<Args...> fmt, Args&&... args);
```

Effects: Equivalent to:

```
return vformat(fmt.str, make_format_args(args...));
```

```
template<class... Args>
wstring format(wformat_string<Args...> fmt, Args&&... args);
```

Effects: Equivalent to:

```
return vformat(fmt.str, make_wformat_args(args...));
```

```
template<class... Args>
string format(const locale& loc, format_string<Args...> fmt, Args&&... args);
```

Effects: Equivalent to:

```
return vformat(loc, fmt.str, make_format_args(args...));
```

```
template<class... Args>
wstring format(const locale& loc, wformat_string<Args...> fmt, Args&&... args);
```

Effects: Equivalent to:

```
return vformat(loc, fmt.str, make_wformat_args(args...));
```

```
string vformat(string_view fmt, format_args args);
wstring vformat(wstring_view fmt, wformat_args args);
string vformat(const locale& loc, string_view fmt, format_args args);
wstring vformat(const locale& loc, wstring_view fmt, wformat_args args);
```

Returns: A string object holding the character representation of formatting arguments provided by `args` formatted according to specifications given in `fmt`. If present, `loc` is used for locale-specific formatting.

Throws: As specified in 22.14.3.

```
template<class Out, class... Args>
Out format_to(Out out, format_string<Args...> fmt, Args&&... args);
```

Effects: Equivalent to:

```
return vformat_to(std::move(out), fmt.str, make_format_args(args...));
```

```
template<class Out, class... Args>
Out format_to(Out out, wformat_string<Args...> fmt, Args&&... args);
```

Effects: Equivalent to:

```
return vformat_to(std::move(out), fmt.str, make_wformat_args(args...));
```

```
template<class Out, class... Args>
Out format_to(Out out, const locale& loc, format_string<Args...> fmt, Args&&... args);
```

Effects: Equivalent to:

```
return vformat_to(std::move(out), loc, fmt.str, make_format_args(args...));
```

```
template<class Out, class... Args>
Out format_to(Out out, const locale& loc, wformat_string<Args...> fmt, Args&&... args);
```

Effects: Equivalent to:

```
return vformat_to(std::move(out), loc, fmt.str, make_wformat_args(args...));
```

```
template<class Out>
Out vformat_to(Out out, string_view fmt, format_args args);
```

```
template<class Out>
Out vformat_to(Out out, wstring_view fmt, wformat_args args);
```

```
template<class Out>
    Out vformat_to(Out out, const locale& loc, string_view fmt, format_args args);
template<class Out>
    Out vformat_to(Out out, const locale& loc, wstring_view fmt, wformat_args args);
```

Let `charT` be `decltype(fmt)::value_type`.

Constraints: `Out` satisfies `output_iterator<const charT&>`.

Preconditions: `Out` models `output_iterator<const charT&>`.

Effects: Places the character representation of formatting the arguments provided by `args`, formatted according to the specifications given in `fmt`, into the range `[out, out + N)`, where `N` is the number of characters in that character representation. If present, `loc` is used for locale-specific formatting.

Returns: `out + N`.

Throws: As specified in 22.14.3.

```
template<class Out, class... Args>
    format_to_n_result<Out> format_to_n(Out out, iter_difference_t<Out> n,
                                         format_string<Args...> fmt, Args&&... args);
template<class Out, class... Args>
    format_to_n_result<Out> format_to_n(Out out, iter_difference_t<Out> n,
                                         wformat_string<Args...> fmt, Args&&... args);
template<class Out, class... Args>
    format_to_n_result<Out> format_to_n(Out out, iter_difference_t<Out> n,
                                         const locale& loc, format_string<Args...> fmt,
                                         Args&&... args);
template<class Out, class... Args>
    format_to_n_result<Out> format_to_n(Out out, iter_difference_t<Out> n,
                                         const locale& loc, wformat_string<Args...> fmt,
                                         Args&&... args);
```

Let

- `charT` be `decltype(fmt.str)::value_type`,
- `N` be `formatted_size(fmt, args...)` for the functions without a `loc` parameter and `formatted_size(loc, fmt, args...)` for the functions with a `loc` parameter, and
- `M` be `clamp(n, 0, N)`.

Constraints: `Out` satisfies `output_iterator<const charT&>`.

Preconditions: `Out` models `output_iterator<const charT&>`, and `formatter<remove_cvref_t<Ti>, charT>` meets the *BasicFormatter* requirements (22.14.6.1) for each `Ti` in `Args`.

Effects: Places the first `M` characters of the character representation of formatting the arguments provided by `args`, formatted according to the specifications given in `fmt`, into the range `[out, out + M)`. If present, `loc` is used for locale-specific formatting.

Returns: `{out + M, N}`.

Throws: As specified in 22.14.3.

```
template<class... Args>
    size_t formatted_size(format_string<Args...> fmt, Args&&... args);
template<class... Args>
    size_t formatted_size(wformat_string<Args...> fmt, Args&&... args);
template<class... Args>
    size_t formatted_size(const locale& loc, format_string<Args...> fmt, Args&&... args);
template<class... Args>
    size_t formatted_size(const locale& loc, wformat_string<Args...> fmt, Args&&... args);
```

Let `charT` be `decltype(fmt.str)::value_type`.

Preconditions: `formatter<remove_cvref_t<Ti>, charT>` meets the *BasicFormatter* requirements (22.14.6.1) for each `Ti` in `Args`.

Returns: The number of characters in the character representation of formatting arguments `args` formatted according to specifications given in `fmt`. If present, `loc` is used for locale-specific formatting.

Throws: As specified in 22.14.3.

22.14.6 Formatter

[format.formatter]

22.14.6.1 Formatter requirements

[formatter.requirements]

A type *F* meets the *BasicFormatter* requirements if it meets the

- *Cpp17DefaultConstructible* (Table 30),
- *Cpp17CopyConstructible* (Table 32),
- *Cpp17CopyAssignable* (Table 34),
- *Cpp17Swappable* (16.4.4.3), and
- *Cpp17Destructible* (Table 35)

requirements, and the expressions shown in Table 73 are valid and have the indicated semantics.

A type *F* meets the *Formatter* requirements if it meets the *BasicFormatter* requirements and the expressions shown in Table 74 are valid and have the indicated semantics.

Given character type *charT*, output iterator type *Out*, and formatting argument type *T*, in Table 73 and Table 74:

- *f* is a value of type (possibly const) *F*,
- *g* is an lvalue of type *F*,
- *u* is an lvalue of type *T*,
- *t* is a value of a type convertible to (possibly const) *T*,
- *PC* is `basic_format_parse_context<charT>`,
- *FC* is `basic_format_context<Out, charT>`,
- *pc* is an lvalue of type *PC*, and
- *fc* is an lvalue of type *FC*.

`pc.begin()` points to the beginning of the *format-spec* (22.14.2) of the replacement field being formatted in the format string. If *format-spec* is empty then either `pc.begin() == pc.end()` or `*pc.begin() == '}'`.

Table 73 — *BasicFormatter* requirements [tab:formatter.basic]

Expression	Return type	Requirement
<code>g.parse(pc)</code>	<code>PC::iterator</code>	Parses <i>format-spec</i> (22.14.2) for type <i>T</i> in the range <code>[pc.begin(), pc.end())</code> until the first unmatched character. Throws <code>format_error</code> unless the whole range is parsed or the unmatched character is <code>}</code> . NOTE This allows formatters to emit meaningful error messages. Stores the parsed format specifiers in <code>*this</code> and returns an iterator past the end of the parsed range.
<code>f.format(u, fc)</code>	<code>FC::iterator</code>	Formats <i>u</i> according to the specifiers stored in <code>*this</code> , writes the output to <code>fc.out()</code> , and returns an iterator past the end of the output range. The output shall only depend on <i>u</i> , <code>fc.locale()</code> , <code>fc.arg(n)</code> for any value <i>n</i> of type <code>size_t</code> , and the range <code>[pc.begin(), pc.end())</code> from the last call to <code>f.parse(pc)</code> .

22.14.6.2 Concept formattable

[format.formattable]

Let *fmt_iter_for*<*charT*> be an unspecified type that models `output_iterator<const charT&>` (25.3.4.10).

Table 74 — *Formatter* requirements [tab:formatter]

Expression	Return type	Requirement
<code>f.format(t, fc)</code>	<code>FC::iterator</code>	Formats <code>t</code> according to the specifiers stored in <code>*this</code> , writes the output to <code>fc.out()</code> , and returns an iterator past the end of the output range. The output shall only depend on <code>t</code> , <code>fc.locale()</code> , <code>fc.arg(n)</code> for any value <code>n</code> of type <code>size_t</code> , and the range <code>[pc.begin(), pc.end())</code> from the last call to <code>f.parse(pc)</code> .
<code>f.format(u, fc)</code>	<code>FC::iterator</code>	As above, but does not modify <code>u</code> .

```

template<class T, class Context,
        class Formatter = typename Context::template formatter_type<remove_const_t<T>>>
concept formattable-with = // exposition only
    semiregular<Formatter> &&
    requires(Formatter& f, const Formatter& cf, T&& t, Context fc,
             basic_format_parse_context<typename Context::char_type> pc)
{
    { f.parse(pc) } -> same_as<typename decltype(pc)::iterator>;
    { cf.format(t, fc) } -> same_as<typename Context::iterator>;
};

template<class T, class charT>
concept formattable =
    formattable-with<remove_reference_t<T>, basic_format_context<fmt-iter-for<charT>>>>;

```

A type `T` and a character type `charT` model `formattable` if `formatter<remove_cvref_t<T>, charT>` meets the *BasicFormatter* requirements (22.14.6.1) and, if `remove_reference_t<T>` is const-qualified, the *Formatter* requirements.

22.14.6.3 Formatter specializations

[format.formatter.spec]

The functions defined in 22.14.5 use specializations of the class template `formatter` to format individual arguments.

Let `charT` be either `char` or `wchar_t`. Each specialization of `formatter` is either enabled or disabled, as described below. A *debug-enabled* specialization of `formatter` additionally provides a public, constexpr, non-static member function `set_debug_format()` which modifies the state of the `formatter` to be as if the type of the *std-format-spec* parsed by the last call to `parse` were `?`. Each header that declares the template `formatter` provides the following enabled specializations:

- The debug-enabled specializations

```

template<> struct formatter<char, char>;
template<> struct formatter<char, wchar_t>;
template<> struct formatter<wchar_t, wchar_t>;

```

- For each `charT`, the debug-enabled string type specializations

```

template<> struct formatter<charT*, charT>;
template<> struct formatter<const charT*, charT>;
template<size_t N> struct formatter<charT[N], charT>;
template<class traits, class Allocator>
    struct formatter<basic_string<charT, traits, Allocator>, charT>;
template<class traits>
    struct formatter<basic_string_view<charT, traits>, charT>;

```

- For each `charT`, for each cv-unqualified arithmetic type `ArithmeticT` other than `char`, `wchar_t`, `char8_t`, `char16_t`, or `char32_t`, a specialization

```

template<> struct formatter<ArithmeticT, charT>;

```

- For each `charT`, the pointer type specializations

```

template<> struct formatter<nullptr_t, charT>;

```

```
template<> struct formatter<void*, charT>;
template<> struct formatter<const void*, charT>;
```

The `parse` member functions of these formatters interpret the format specification as a *std-format-spec* as described in 22.14.2.2.

NOTE Specializations such as `formatter<wchar_t, char>` and `formatter<const char*, wchar_t>` that would require implicit multibyte / wide string or character conversion are disabled.

For any types `T` and `charT` for which neither the library nor the user provides an explicit or partial specialization of the class template `formatter`, `formatter<T, charT>` is disabled.

If the library provides an explicit or partial specialization of `formatter<T, charT>`, that specialization is enabled and meets the *Formatter* requirements except as noted otherwise.

If `F` is a disabled specialization of `formatter`, these values are false:

- `is_default_constructible_v<F>`,
- `is_copy_constructible_v<F>`,
- `is_move_constructible_v<F>`,
- `is_copy_assignable_v<F>`, and
- `is_move_assignable_v<F>`.

An enabled specialization `formatter<T, charT>` meets the *BasicFormatter* requirements (22.14.6.1).

EXAMPLE

```
#include <format>

enum color { red, green, blue };
const char* color_names[] = { "red", "green", "blue" };

template<> struct std::formatter<color> : std::formatter<const char*> {
    auto format(color c, format_context& ctx) const {
        return formatter<const char*>::format(color_names[c], ctx);
    }
};

struct err {};

std::string s0 = std::format("{} ", 42);           // OK, library-provided formatter
std::string s1 = std::format("{} ", L"foo");       // error: disabled formatter
std::string s2 = std::format("{} ", red);          // OK, user-provided formatter
std::string s3 = std::format("{} ", err{});        // error: disabled formatter
```

22.14.6.4 Formatting escaped characters and strings [format.string.escaped]

A character or string can be formatted as *escaped* to make it more suitable for debugging or for logging.

The escaped string *E* representation of a string *S* is constructed by encoding a sequence of characters as follows. The associated character encoding *CE* for `charT` (Table 12) is used to both interpret *S* and construct *E*.

- U+0022 QUOTATION MARK (") is appended to *E*.
- For each code unit sequence *X* in *S* that either encodes a single character, is a shift sequence, or is a sequence of ill-formed code units, processing is in order as follows:
 - If *X* encodes a single character *C*, then:
 - If *C* is one of the characters in Table 75, then the two characters shown as the corresponding escape sequence are appended to *E*.
 - Otherwise, if *C* is not U+0020 SPACE and
 - *CE* is UTF-8, UTF-16, or UTF-32 and *C* corresponds to a Unicode scalar value whose Unicode property `General_Category` has a value in the groups `Separator` (Z) or `Other` (C), as described by UAX #44 of the Unicode Standard, or
 - *CE* is UTF-8, UTF-16, or UTF-32 and *C* corresponds to a Unicode scalar value with the Unicode property `Grapheme_Extend=Yes` as described by UAX #44 of the Unicode

Standard and *C* is not immediately preceded in *S* by a character *P* appended to *E* without translation to an escape sequence, or

- *CE* is neither UTF-8, UTF-16, nor UTF-32 and *C* is one of an implementation-defined set of separator or non-printable characters

then the sequence `\u{hex-digit-sequence}` is appended to *E*, where *hex-digit-sequence* is the shortest hexadecimal representation of *C* using lower-case hexadecimal digits.

- Otherwise, *C* is appended to *E*.

- Otherwise, if *X* is a shift sequence, the effect on *E* and further decoding of *S* is unspecified.

Recommended practice: A shift sequence should be represented in *E* such that the original code unit sequence of *S* can be reconstructed.

- Otherwise (*X* is a sequence of ill-formed code units), each code unit *U* is appended to *E* in order as the sequence `\x{hex-digit-sequence}`, where *hex-digit-sequence* is the shortest hexadecimal representation of *U* using lower-case hexadecimal digits.

- Finally, U+0022 QUOTATION MARK (") is appended to *E*.

Table 75 — Mapping of characters to escape sequences [tab:format.escape.sequences]

Character	Escape sequence
U+0009 CHARACTER TABULATION	<code>\t</code>
U+000A LINE FEED	<code>\n</code>
U+000D CARRIAGE RETURN	<code>\r</code>
U+0022 QUOTATION MARK	<code>\"</code>
U+005C REVERSE SOLIDUS	<code>\\</code>

The escaped string representation of a character *C* is equivalent to the escaped string representation of a string of *C*, except that:

- the result starts and ends with U+0027 APOSTROPHE (') instead of U+0022 QUOTATION MARK ("), and
- if *C* is U+0027 APOSTROPHE, the two characters `\'` are appended to *E*, and
- if *C* is U+0022 QUOTATION MARK, then *C* is appended unchanged.

EXAMPLE

```
string s0 = format("{} ", "h\tllo");           // s0 has value: [h  llo]
string s1 = format("{}:?}", "h\tllo");         // s1 has value: ["h\tllo"]
string s2 = format("{}:?", "Спасибо, Виктор ♥!"); // s2 has value: ["Спасибо, Виктор ♥!"]
string s3 = format("{}:?", "{:?}", '\'', '"'); // s3 has value: ['\'', '"']

// The following examples assume use of the UTF-8 encoding
string s4 = format("{}:?", string("\0 \n \t \x02 \x1b", 9));
// s4 has value: ["\u{0} \n \t \u{2} \u{1b}"]
string s5 = format("{}:?", "\xc3\x28");         // invalid UTF-8, s5 has value: ["\x{c3}("]
string s6 = format("{}:?", "🇪🇺");             // s6 has value: ["\u{200d}\u{fe0f}"]
string s7 = format("{}:?", "\u0301");           // s7 has value: ["\u{301}"]
string s8 = format("{}:?", "\\u0301");          // s8 has value: ["\\u{301}"]
string s9 = format("{}:?", "e\u0301\u0323");    // s9 has value: ["ë"]
```

22.14.6.5 Class template `basic_format_parse_context`

[format.parse.ctx]

```
namespace std {
    template<class charT>
    class basic_format_parse_context {
    public:
        using char_type = charT;
        using const_iterator = typename basic_string_view<charT>::const_iterator;
        using iterator = const_iterator;

    private:
        iterator begin_;           // exposition only
    };
}
```

```

    iterator end_; // exposition only
    enum indexing { unknown, manual, automatic }; // exposition only
    indexing indexing_; // exposition only
    size_t next_arg_id_; // exposition only
    size_t num_args_; // exposition only

public:
    constexpr explicit basic_format_parse_context(basic_string_view<charT> fmt,
                                                  size_t num_args = 0) noexcept;
    basic_format_parse_context(const basic_format_parse_context&) = delete;
    basic_format_parse_context& operator=(const basic_format_parse_context&) = delete;

    constexpr const_iterator begin() const noexcept;
    constexpr const_iterator end() const noexcept;
    constexpr void advance_to(const_iterator it);

    constexpr size_t next_arg_id();
    constexpr void check_arg_id(size_t id);
};

```

An instance of `basic_format_parse_context` holds the format string parsing state consisting of the format string range being parsed and the argument counter for automatic indexing.

```

constexpr explicit basic_format_parse_context(basic_string_view<charT> fmt,
                                              size_t num_args = 0) noexcept;

```

Effects: Initializes `begin_` with `fmt.begin()`, `end_` with `fmt.end()`, `indexing_` with `unknown`, `next_arg_id_` with `0`, and `num_args_` with `num_args`.

```
constexpr const_iterator begin() const noexcept;
```

Returns: `begin_`.

```
constexpr const_iterator end() const noexcept;
```

Returns: `end_`.

```
constexpr void advance_to(const_iterator it);
```

Preconditions: `end()` is reachable from `it`.

Effects: Equivalent to: `begin_ = it;`

```
constexpr size_t next_arg_id();
```

Effects: If `indexing_ != manual` is true, equivalent to:

```

    if (indexing_ == unknown)
        indexing_ = automatic;
    return next_arg_id_++;

```

Throws: `format_error` if `indexing_ == manual` is true which indicates mixing of automatic and manual argument indexing.

Remarks: Let *cur-arg-id* be the value of `next_arg_id_` prior to this call. Call expressions where *cur-arg-id* $\geq$ `num_args_` is true are not core constant expressions (7.7).

```
constexpr void check_arg_id(size_t id);
```

Effects: If `indexing_ != automatic` is true, equivalent to:

```

    if (indexing_ == unknown)
        indexing_ = manual;

```

Throws: `format_error` if `indexing_ == automatic` is true which indicates mixing of automatic and manual argument indexing.

Remarks: Call expressions where `id` $\geq$ `num_args_` is true are not core constant expressions (7.7).

22.14.6.6 Class template `basic_format_context`

[format.context]

```

namespace std {
    template<class Out, class charT>
    class basic_format_context {
        basic_format_args<basic_format_context> args_;           // exposition only
        Out out_;                                                 // exposition only

    public:
        using iterator = Out;
        using char_type = charT;
        template<class T> using formatter_type = formatter<T, charT>;

        basic_format_arg<basic_format_context> arg(size_t id) const noexcept;
        std::locale locale();

        iterator out();
        void advance_to(iterator it);
    };
}

```

An instance of `basic_format_context` holds formatting state consisting of the formatting arguments and the output iterator.

`Out` shall model `output_iterator<const charT&>`.

`format_context` is an alias for a specialization of `basic_format_context` with an output iterator that appends to `string`, such as `back_insert_iterator<string>`. Similarly, `wformat_context` is an alias for a specialization of `basic_format_context` with an output iterator that appends to `wstring`.

Recommended practice: For a given type `charT`, implementations should provide a single instantiation of `basic_format_context` for appending to `basic_string<charT>`, `vector<charT>`, or any other container with contiguous storage by wrapping those in temporary objects with a uniform interface (such as a `span<charT>`) and polymorphic reallocation.

```
basic_format_arg<basic_format_context> arg(size_t id) const noexcept;
```

Returns: `args_.get(id)`.

```
std::locale locale();
```

Returns: The locale passed to the formatting function if the latter takes one, and `std::locale()` otherwise.

```
iterator out();
```

Effects: Equivalent to: `return std::move(out_);`

```
void advance_to(iterator it);
```

Effects: Equivalent to: `out_ = std::move(it);`

EXAMPLE

```

struct S { int value; };

template<> struct std::formatter<S> {
    size_t width_arg_id = 0;

    // Parses a width argument id in the format { digit }.
    constexpr auto parse(format_parse_context& ctx) {
        auto iter = ctx.begin();
        auto get_char = [&]() { return iter != ctx.end() ? *iter : 0; };
        if (get_char() != '{')
            return iter;
        ++iter;
        char c = get_char();
        if (!isdigit(c) || (++iter, get_char()) != '}')
            throw format_error("invalid format");
        width_arg_id = c - '0';
    }
};

```

```

    ctx.check_arg_id(width_arg_id);
    return ++iter;
}

// Formats an S with width given by the argument width_arg_id.
auto format(S s, format_context& ctx) const {
    int width = visit_format_arg([](auto value) -> int {
        if constexpr (!is_integral_v<decltype(value)>))
            throw format_error("width is not integral");
        else if (value < 0 || value > numeric_limits<int>::max())
            throw format_error("invalid width");
        else
            return value;
    }, ctx.arg(width_arg_id));
    return format_to(ctx.out(), "{0:x<{1}}", s.value, width);
}
};

std::string s = std::format("{0:1}", S{42}, 10); // value of s is "xxxxxxx42"

```

22.14.7 Formatting of ranges [format.range]

22.14.7.1 Variable template `format_kind` [format.range.fmtkind]

```

template<ranges::input_range R>
    requires same_as<R, remove_cvref_t<R>>
constexpr range_format format_kind<R> = see below;

```

A program that instantiates the primary template of `format_kind` is ill-formed.

For a type `R`, `format_kind<R>` is defined as follows:

- If `same_as<remove_cvref_t<ranges::range_reference_t<R>>, R>` is true, `format_kind<R>` is `range_format::disabled`.
- NOTE This prevents constraint recursion for ranges whose reference type is the same range type. For example, `std::filesystem::path` is a range of `std::filesystem::path`.
- Otherwise, if the *qualified-id* `R::key_type` is valid and denotes a type:
 - If the *qualified-id* `R::mapped_type` is valid and denotes a type, let `U` be `remove_cvref_t<ranges::range_reference_t<R>>`. If either `U` is a specialization of `pair` or `U` is a specialization of `tuple` and `tuple_size_v<U> == 2`, `format_kind<R>` is `range_format::map`.
 - Otherwise, `format_kind<R>` is `range_format::set`.
 - Otherwise, `format_kind<R>` is `range_format::sequence`.

Remarks: Pursuant to 16.4.5.2.1, users may specialize `format_kind` for cv-unqualified program-defined types that model `ranges::input_range`. Such specializations shall be usable in constant expressions (7.7) and have type `const range_format`.

22.14.7.2 Class template `range_formatter` [format.range.formatter]

```

namespace std {
    template<class T, class charT = char>
        requires same_as<remove_cvref_t<T>, T> && formattable<T, charT>
        class range_formatter {
            formatter<T, charT> underlying_; // exposition only
            basic_string_view<charT> separator_ = STATICALLY-WIDEN<charT>(" "); // exposition only
            basic_string_view<charT> opening_bracket_ = STATICALLY-WIDEN<charT>("["); // exposition only
            basic_string_view<charT> closing_bracket_ = STATICALLY-WIDEN<charT>("]"); // exposition only

        public:
            constexpr void set_separator(basic_string_view<charT> sep) noexcept;
            constexpr void set_brackets(basic_string_view<charT> opening,
                                         basic_string_view<charT> closing) noexcept;
            constexpr formatter<T, charT>& underlying() noexcept { return underlying_; }
            constexpr const formatter<T, charT>& underlying() const noexcept { return underlying_; }

```

```

template<class ParseContext>
constexpr typename ParseContext::iterator
    parse(ParseContext& ctx);

template<ranges::input_range R, class FormatContext>
    requires formattable<ranges::range_reference_t<R>, charT> &&
        same_as<remove_cvref_t<ranges::range_reference_t<R>>, T>
    typename FormatContext::iterator
        format(R&& r, FormatContext& ctx) const;
};
}

```

The class template `range_formatter` is a utility for implementing `formatter` specializations for range types. `range_formatter` interprets *format-spec* as a *range-format-spec*. The syntax of format specifications is as follows:

```

range-format-spec:
    range-fill-and-alignopt widthopt nopt range-typeopt range-underlying-specopt

range-fill-and-align:
    range-fillopt align

range-fill:
    any character other than { or } or :

range-type:
    m
    s
    ?s

range-underlying-spec:
    : format-spec

```

For `range_formatter<T, charT>`, the *format-spec* in a *range-underlying-spec*, if any, is interpreted by `formatter<T, charT>`.

The *range-fill-and-align* is interpreted the same way as a *fill-and-align* (22.14.2.2). The productions *align* and *width* are described in 22.14.2.

The *n* option causes the range to be formatted without the opening and closing brackets.

NOTE 1 This is equivalent to invoking `set_brackets({}, {})`.

The *range-type* specifier changes the way a range is formatted, with certain options only valid with certain argument types. The meaning of the various type options is as specified in Table 76.

Table 76 — Meaning of *range-type* options [tab:formatter.range.type]

Option	Requirements	Meaning
m	T shall be either a specialization of <code>pair</code> or a specialization of <code>tuple</code> such that <code>tuple_size_v<T></code> is 2.	Indicates that the opening bracket should be "{", the closing bracket should be "}", the separator should be ", ", and each range element should be formatted as if m were specified for its <i>tuple-type</i> . NOTE 2 If the <i>n</i> option is provided in addition to the m option, both the opening and closing brackets are still empty.
s	T shall be <code>charT</code> .	Indicates that the range should be formatted as a string .
?s	T shall be <code>charT</code> .	Indicates that the range should be formatted as an escaped string (22.14.6.4).

If the *range-type* is **s** or **?s**, then there shall be no *n* option and no *range-underlying-spec*.

```
constexpr void set_separator(basic_string_view<charT> sep) noexcept;
```

Effects: Equivalent to: `separator_ = sep;`

```
constexpr void set_brackets(basic_string_view<charT> opening,
                           basic_string_view<charT> closing) noexcept;
```

Effects: Equivalent to:

```
opening-bracket_ = opening;
closing-bracket_ = closing;
```

```
template<class ParseContext>
constexpr typename ParseContext::iterator
parse(ParseContext& ctx);
```

Effects: Parses the format specifier as a *range-format-spec* and stores the parsed specifiers in **this*. The values of *opening-bracket_*, *closing-bracket_*, and *separator_* are modified if and only if required by the *range-type* or the *n* option, if present. If:

- the *range-type* is neither *s* nor *?s*,
- *underlying_.set_debug_format()* is a valid expression, and
- there is no *range-underlying-spec*,

then calls *underlying_.set_debug_format()*.

Returns: An iterator past the end of the *range-format-spec*.

```
template<ranges::input_range R, class FormatContext>
requires formattable<ranges::range_reference_t<R>, charT> &&
same_as<remove_cvref_t<ranges::range_reference_t<R>>, T>
typename FormatContext::iterator
format(R&& r, FormatContext& ctx) const;
```

Effects: Writes the following into *ctx.out()*, adjusted according to the *range-format-spec*:

- If the *range-type* was *s*, then as if by formatting *basic_string<charT>(from_range, r)*.
- Otherwise, if the *range-type* was *?s*, then as if by formatting *basic_string<charT>(from_range, r)* as an escaped string (22.14.6.4).
- Otherwise,
 - *opening-bracket_*,
 - for each element *e* of the range *r*:
 - the result of writing *e* via *underlying_* and
 - *separator_*, unless *e* is the last element of *r*, and
 - *closing-bracket_*.

Returns: An iterator past the end of the output range.

22.14.7.3 Class template *range-default-formatter*

[format.range.fmtdef]

```
namespace std {
template<ranges::input_range R, class charT>
struct range_default_formatter<range_format::sequence, R, charT> { // exposition only
private:
    using maybe_const_r = fmt_maybe_const<R, charT>; // exposition only
    range_formatter<remove_cvref_t<ranges::range_reference_t<maybe_const_r>>,
                   charT> underlying_; // exposition only

public:
    constexpr void set_separator(basic_string_view<charT> sep) noexcept;
    constexpr void set_brackets(basic_string_view<charT> opening,
                                basic_string_view<charT> closing) noexcept;

    template<class ParseContext>
    constexpr typename ParseContext::iterator
    parse(ParseContext& ctx);
```

```

    template<class FormatContext>
        typename FormatContext::iterator
        format(maybe-const-r& elems, FormatContext& ctx) const;
};
}

constexpr void set_separator(basic_string_view<charT> sep) noexcept;
    Effects: Equivalent to: underlying_.set_separator(sep);

constexpr void set_brackets(basic_string_view<charT> opening,
                            basic_string_view<charT> closing) noexcept;
    Effects: Equivalent to: underlying_.set_brackets(opening, closing);

template<class ParseContext>
    constexpr typename ParseContext::iterator
    parse(ParseContext& ctx);
    Effects: Equivalent to: return underlying_.parse(ctx);

template<class FormatContext>
    typename FormatContext::iterator
    format(maybe-const-r& elems, FormatContext& ctx) const;
    Effects: Equivalent to: return underlying_.format(elems, ctx);

```

22.14.7.4 Specialization of *range-default-formatter* for maps [format.range.fmtmap]

```

namespace std {
    template<ranges::input_range R, class charT>
    struct range-default-formatter<range_format::map, R, charT> {
    private:
        using maybe-const-map = fmt-maybe-const<R, charT>; // exposition only
        using element-type = // exposition only
            remove_cvref_t<ranges::range_reference_t<maybe-const-map>>;
        range_formatter<element-type, charT> underlying_; // exposition only

    public:
        constexpr range-default-formatter();

        template<class ParseContext>
            constexpr typename ParseContext::iterator
            parse(ParseContext& ctx);

        template<class FormatContext>
            typename FormatContext::iterator
            format(maybe-const-map& r, FormatContext& ctx) const;
    };
}

constexpr range-default-formatter();
    Mandates: Either:
    — element-type is a specialization of pair, or
    — element-type is a specialization of tuple and tuple_size_v<element-type> == 2.
    Effects: Equivalent to:
        underlying_.set_brackets(STATICALLY-WIDEN<charT>("{", STATICALLY-WIDEN<charT>("}"));
        underlying_.underlying().set_brackets({, {});
        underlying_.underlying().set_separator(STATICALLY-WIDEN<charT>(": "));

template<class ParseContext>
    constexpr typename ParseContext::iterator
    parse(ParseContext& ctx);
    Effects: Equivalent to: return underlying_.parse(ctx);

```

```
template<class FormatContext>
    typename FormatContext::iterator
    format(maybe-const-map& r, FormatContext& ctx) const;

    Effects: Equivalent to: return underlying_.format(r, ctx);
```

22.14.7.5 Specialization of *range-default-formatter* for sets [format.range.fmtset]

```
namespace std {
    template<ranges::input_range R, class charT>
    struct range-default-formatter<range_format::set, R, charT> {
    private:
        using maybe-const-set = fmt-maybe-const<R, charT>; // exposition only
        range_formatter<remove_cvref_t<ranges::range_reference_t<maybe-const-set>>,
            charT> underlying_; // exposition only

    public:
        constexpr range-default-formatter();

        template<class ParseContext>
            constexpr typename ParseContext::iterator
            parse(ParseContext& ctx);

        template<class FormatContext>
            typename FormatContext::iterator
            format(maybe-const-set& r, FormatContext& ctx) const;
    };
}

constexpr range-default-formatter();

Effects: Equivalent to:

    underlying_.set_brackets(STATICALLY-WIDEN<charT>("{"), STATICALLY-WIDEN<charT>("}"));

template<class ParseContext>
    constexpr typename ParseContext::iterator
    parse(ParseContext& ctx);

    Effects: Equivalent to: return underlying_.parse(ctx);

template<class FormatContext>
    typename FormatContext::iterator
    format(maybe-const-set& r, FormatContext& ctx) const;

    Effects: Equivalent to: return underlying_.format(r, ctx);
```

22.14.7.6 Specialization of *range-default-formatter* for strings [format.range.fmtstr]

```
namespace std {
    template<range_format K, ranges::input_range R, class charT>
        requires (K == range_format::string || K == range_format::debug_string)
    struct range-default-formatter<K, R, charT> {
    private:
        formatter<basic_string<charT>, charT> underlying_; // exposition only

    public:
        template<class ParseContext>
            constexpr typename ParseContext::iterator
            parse(ParseContext& ctx);

        template<class FormatContext>
            typename FormatContext::iterator
            format(see below& str, FormatContext& ctx) const;
    };
}
```

Mandates: *same_as*<remove_cvref_t<range_reference_t<R>>, charT> is true.

```

template<class ParseContext>
constexpr typename ParseContext::iterator
parse(ParseContext& ctx);

Effects: Equivalent to:

    auto i = underlying_.parse(ctx);
    if constexpr (K == range_format::debug_string) {
        underlying_.set_debug_format();
    }
    return i;

template<class FormatContext>
typename FormatContext::iterator
format(see below& r, FormatContext& ctx) const;

The type of r is const R& if ranges::input_range<const R> is true and R& otherwise.

Effects: Let s be a basic_string<charT> such that ranges::equal(s, r) is true. Equivalent to:
return underlying_.format(s, ctx);

```

22.14.8 Arguments

[format.arguments]

22.14.8.1 Class template basic_format_arg

[format.arg]

```

namespace std {
    template<class Context>
    class basic_format_arg {
    public:
        class handle;

    private:
        using char_type = typename Context::char_type;

        variant<monostate, bool, char_type,
            int, unsigned int, long long int, unsigned long long int,
            float, double, long double,
            const char_type*, basic_string_view<char_type>,
            const void*, handle> value;

        template<class T> explicit basic_format_arg(T& v) noexcept;

    public:
        basic_format_arg() noexcept;

        explicit operator bool() const noexcept;
    };
}

```

An instance of `basic_format_arg` provides access to a formatting argument for user-defined formatters. The behavior of a program that adds specializations of `basic_format_arg` is undefined.

```
basic_format_arg() noexcept;
```

Postconditions: `!(*this)`.

```
template<class T> explicit basic_format_arg(T& v) noexcept;
```

Constraints: T satisfies *formattable-with*<Context>.

Preconditions: If `decay_t<T>` is `char_type*` or `const char_type*`, `static_cast<const char_type*>(v)` points to a NTCTS (3.34).

Effects: Let TD be `remove_const_t<T>`.

- If TD is `bool` or `char_type`, initializes value with `v`;
- otherwise, if TD is `char` and `char_type` is `wchar_t`, initializes value with `static_cast<wchar_t>(v)`;

- otherwise, if TD is a signed integer type (6.8.2) and `sizeof(TD) <= sizeof(int)`, initializes value with `static_cast<int>(v)`;
- otherwise, if TD is an unsigned integer type and `sizeof(TD) <= sizeof(unsigned int)`, initializes value with `static_cast<unsigned int>(v)`;
- otherwise, if TD is a signed integer type and `sizeof(TD) <= sizeof(long long int)`, initializes value with `static_cast<long long int>(v)`;
- otherwise, if TD is an unsigned integer type and `sizeof(TD) <= sizeof(unsigned long long int)`, initializes value with `static_cast<unsigned long long int>(v)`;
- otherwise, if TD is a standard floating-point type, initializes value with `v`;
- otherwise, if TD is a specialization of `basic_string_view` or `basic_string` and `TD::value_type` is `char_type`, initializes value with `basic_string_view<char_type>(v.data(), v.size())`;
- otherwise, if `decay_t<TD>` is `char_type*` or `const char_type*`, initializes value with `static_cast<const char_type*>(v)`;
- otherwise, if `is_void_v<remove_pointer_t<TD>>` is true or `is_null_pointer_v<TD>` is true, initializes value with `static_cast<const void*>(v)`;
- otherwise, initializes value with `handle(v)`.

NOTE Constructing `basic_format_arg` from a pointer to a member is ill-formed unless the user provides an enabled specialization of `formatter` for that pointer to member type.

`explicit operator bool() const noexcept;`

Returns: `!holds_alternative<monostate>(value)`.

The class `handle` allows formatting an object of a user-defined type.

```
namespace std {
    template<class Context>
    class basic_format_arg<Context>::handle {
        const void* ptr_;
        void (*format_)(basic_format_parse_context<char_type>&,
                        Context&, const void*);

        template<class T> explicit handle(T& val) noexcept;

        friend class basic_format_arg<Context>;

    public:
        void format(basic_format_parse_context<char_type>&, Context& ctx) const;
    };
}
```

`template<class T> explicit handle(T& val) noexcept;`

Let

- TD be `remove_const_t<T>`,
- TQ be `const TD` if `const TD` satisfies *formattable-with*<Context> and TD otherwise.

Mandates: TQ satisfies *formattable-with*<Context>.

Effects: Initializes `ptr_` with `addressof(val)` and `format_` with

```
[& (basic_format_parse_context<char_type>& parse_ctx,
    Context& format_ctx, const void* ptr) {
    typename Context::template formatter_type<TD> f;
    parse_ctx.advance_to(f.parse(parse_ctx));
    format_ctx.advance_to(f.format(*const_cast<TQ*>(static_cast<const TD*>(ptr)),
                                format_ctx));
}]
```

`void format(basic_format_parse_context<char_type>& parse_ctx, Context& format_ctx) const;`

Effects: Equivalent to: `format_(parse_ctx, format_ctx, ptr_);`

```
template<class Visitor, class Context>
  decltype(auto) visit_format_arg(Visitor&& vis, basic_format_arg<Context> arg);
Effects: Equivalent to: return visit(std::forward<Visitor>(vis), arg.value);
```

22.14.8.2 Class template *format-arg-store* [format.arg.store]

```
namespace std {
  template<class Context, class... Args>
  class format-arg-store {
    array<basic_format_arg<Context>, sizeof...(Args)> args; // exposition only
  }; // exposition only
}
```

An instance of *format-arg-store* stores formatting arguments.

```
template<class Context = format_context, class... Args>
  format-arg-store<Context, Args...> make_format_args(Args&&... fmt_args);
```

Preconditions: The type `typename Context::template formatter_type<remove_cvref_t<Ti>>` meets the *BasicFormatter* requirements (22.14.6.1) for each T_i in *Args*.

Returns: An object of type *format-arg-store*<Context, Args...> whose *args* data member is initialized with {*basic_format_arg*<Context>(fmt_args)...}.

```
template<class... Args>
  format-arg-store<wformat_context, Args...> make_wformat_args(Args&&... args);
Effects: Equivalent to: return make_format_args<wformat_context>(args...);
```

22.14.8.3 Class template *basic_format_args* [format.args]

```
namespace std {
  template<class Context>
  class basic_format_args {
    size_t size_; // exposition only
    const basic_format_arg<Context>* data_; // exposition only

  public:
    basic_format_args() noexcept;

    template<class... Args>
      basic_format_args(const format-arg-store<Context, Args...>& store) noexcept;

    basic_format_arg<Context> get(size_t i) const noexcept;
  };

  template<class Context, class... Args>
    basic_format_args(format-arg-store<Context, Args...> -> basic_format_args<Context>;
}
```

An instance of *basic_format_args* provides access to formatting arguments. Implementations should optimize the representation of *basic_format_args* for a small number of formatting arguments.

NOTE For example, by storing indices of type alternatives separately from values and packing the former.

```
basic_format_args() noexcept;
```

Effects: Initializes *size_* with 0.

```
template<class... Args>
  basic_format_args(const format-arg-store<Context, Args...>& store) noexcept;
Effects: Initializes size_ with sizeof...(Args) and data_ with store.args.data().
```

```
basic_format_arg<Context> get(size_t i) const noexcept;
```

Returns: `i < size_ ? data_[i] : basic_format_arg<Context>()`.

22.14.9 Tuple formatter

[format.tuple]

For each of `pair` and `tuple`, the library provides the following formatter specialization where *pair-or-tuple* is the name of the template:

```
namespace std {
    template<class charT, formattable<charT>... Ts>
    struct formatter<pair-or-tuple<Ts...>, charT> {
    private:
        tuple<formatter<remove_cvref_t<Ts>, charT>...> underlying_;           // exposition only
        basic_string_view<charT> separator_ = STATICALLY-WIDEN<charT>(", "); // exposition only
        basic_string_view<charT> opening-bracket_ = STATICALLY-WIDEN<charT>("("); // exposition only
        basic_string_view<charT> closing-bracket_ = STATICALLY-WIDEN<charT>(")"); // exposition only

    public:
        constexpr void set_separator(basic_string_view<charT> sep) noexcept;
        constexpr void set_brackets(basic_string_view<charT> opening,
                                     basic_string_view<charT> closing) noexcept;

        template<class ParseContext>
        constexpr typename ParseContext::iterator
            parse(ParseContext& ctx);

        template<class FormatContext>
        typename FormatContext::iterator
            format(see below& elems, FormatContext& ctx) const;
    };
}
```

The `parse` member functions of these formatters interpret the format specification as a *tuple-format-spec* according to the following syntax:

```
tuple-format-spec:
    tuple-fill-and-alignopt widthopt tuple-typeopt

tuple-fill-and-align:
    tuple-fillopt align

tuple-fill:
    any character other than { or } or _

tuple-type:
    m
    n
```

The *tuple-fill-and-align* is interpreted the same way as a *fill-and-align* (22.14.2.2). The productions *align* and *width* are described in 22.14.2.

The *tuple-type* specifier changes the way a `pair` or `tuple` is formatted, with certain options only valid with certain argument types. The meaning of the various type options is as specified in Table 77.

Table 77 — Meaning of *tuple-type* options [tab:formatter.tuple.type]

Option	Requirements	Meaning
m	<code>sizeof...(Ts) == 2</code>	Equivalent to: <code>set_separator(STATICALLY-WIDEN<charT>(": "));</code> <code>set_brackets({}, {});</code>
n	none	Equivalent to: <code>set_brackets({}, {});</code>
none	none	No effects

```
constexpr void set_separator(basic_string_view<charT> sep) noexcept;
```

Effects: Equivalent to: `separator_ = sep;`

```
constexpr void set_brackets(basic_string_view<charT> opening,
                           basic_string_view<charT> closing) noexcept;
```

Effects: Equivalent to:

```
opening-bracket_ = opening;
closing-bracket_ = closing;
```

```
template<class ParseContext>
constexpr typename ParseContext::iterator
parse(ParseContext& ctx);
```

Effects: Parses the format specifier as a *tuple-format-spec* and stores the parsed specifiers in **this*. The values of *opening-bracket_*, *closing-bracket_*, and *separator_* are modified if and only if required by the *tuple-type*, if present. For each element *e* in *underlying_*, if *e.set_debug_format()* is a valid expression, calls *e.set_debug_format()*.

Returns: An iterator past the end of the *tuple-format-spec*.

```
template<class FormatContext>
typename FormatContext::iterator
format(see below& elems, FormatContext& ctx) const;
```

The type of *elems* is:

- If `(formattable<const Ts, charT> && ...)` is true, const *pair-or-tuple*<Ts...>&.
- Otherwise *pair-or-tuple*<Ts...>&.

Effects: Writes the following into *ctx.out()*, adjusted according to the *tuple-format-spec*:

- *opening-bracket_*,
- for each index *I* in the `[0, sizeof...(Ts))`:
 - if *I* != 0, *separator_*,
 - the result of writing `get<I>(elems)` via `get<I>(underlying_)`, and
- *closing-bracket_*.

Returns: An iterator past the end of the output range.

22.14.10 Class `format_error`

[format.error]

```
namespace std {
  class format_error : public runtime_error {
  public:
    explicit format_error(const string& what_arg);
    explicit format_error(const char* what_arg);
  };
}
```

The class `format_error` defines the type of objects thrown as exceptions to report errors from the formatting library.

```
format_error(const string& what_arg);
```

Postconditions: `strcmp(what(), what_arg.c_str()) == 0`.

```
format_error(const char* what_arg);
```

Postconditions: `strcmp(what(), what_arg) == 0`.

22.15 Bit manipulation

[bit]

22.15.1 General

[bit.general]

The header `<bit>` provides components to access, manipulate and process both individual bits and bit sequences.

22.15.2 Header <bit> synopsis**[bit.syn]**

```

// all freestanding
namespace std {
    // 22.15.3, bit_cast
    template<class To, class From>
        constexpr To bit_cast(const From& from) noexcept;

    // 22.15.4, byteswap
    template<class T>
        constexpr T byteswap(T value) noexcept;

    // 22.15.5, integral powers of 2
    template<class T>
        constexpr bool has_single_bit(T x) noexcept;
    template<class T>
        constexpr T bit_ceil(T x);
    template<class T>
        constexpr T bit_floor(T x) noexcept;
    template<class T>
        constexpr int bit_width(T x) noexcept;

    // 22.15.6, rotating
    template<class T>
        [[nodiscard]] constexpr T rotl(T x, int s) noexcept;
    template<class T>
        [[nodiscard]] constexpr T rotr(T x, int s) noexcept;

    // 22.15.7, counting
    template<class T>
        constexpr int countl_zero(T x) noexcept;
    template<class T>
        constexpr int countl_one(T x) noexcept;
    template<class T>
        constexpr int countr_zero(T x) noexcept;
    template<class T>
        constexpr int countr_one(T x) noexcept;
    template<class T>
        constexpr int popcount(T x) noexcept;

    // 22.15.8, endian
    enum class endian {
        little = see below,
        big    = see below,
        native = see below
    };
}

```

22.15.3 Function template bit_cast**[bit.cast]**

```

template<class To, class From>
    constexpr To bit_cast(const From& from) noexcept;

```

Constraints:

- `sizeof(To) == sizeof(From)` is true;
- `is_trivially_copyable_v<To>` is true; and
- `is_trivially_copyable_v<From>` is true.

Returns: An object of type `To`. Implicitly creates objects nested within the result (6.7.2). Each bit of the value representation of the result is equal to the corresponding bit in the object representation of `from`. Padding bits of the result are unspecified. For the result and each object created within it, if there is no value of the object's type corresponding to the value representation produced, the behavior is undefined. If there are multiple such values, which value is produced is unspecified. A bit in the value representation of the result is indeterminate if it does not correspond to a bit in the value

representation of **from** or corresponds to a bit of an object that is not within its lifetime or has an indeterminate value (6.7.4). For each bit in the value representation of the result that is indeterminate, the smallest object containing that bit has an indeterminate value; the behavior is undefined unless that object is of unsigned ordinary character type or `std::byte` type. The result does not otherwise contain any indeterminate values.

Remarks: This function is `constexpr` if and only if **To**, **From**, and the types of all subobjects of **To** and **From** are types **T** such that:

- `is_union_v<T>` is false;
- `is_pointer_v<T>` is false;
- `is_member_pointer_v<T>` is false;
- `is_volatile_v<T>` is false; and
- **T** has no non-static data members of reference type.

22.15.4 `byteswap`

[`bit.byteswap`]

```
template<class T>
constexpr T byteswap(T value) noexcept;
```

Constraints: **T** models `integral`.

Mandates: **T** does not have padding bits (6.8.1).

Let the sequence *R* comprise the bytes of the object representation of **value** in reverse order.

Returns: An object **v** of type **T** such that each byte in the object representation of **v** is equal to the byte in the corresponding position in *R*.

22.15.5 `Integral powers of 2`

[`bit.pow.two`]

```
template<class T>
constexpr bool has_single_bit(T x) noexcept;
```

Constraints: **T** is an unsigned integer type (6.8.2).

Returns: `true` if **x** is an integral power of two; `false` otherwise.

```
template<class T>
constexpr T bit_ceil(T x);
```

Let *N* be the smallest power of 2 greater than or equal to **x**.

Constraints: **T** is an unsigned integer type (6.8.2).

Preconditions: *N* is representable as a value of type **T**.

Returns: *N*.

Throws: Nothing.

Remarks: A function call expression that violates the precondition in the *Preconditions:* element is not a core constant expression (7.7).

```
template<class T>
constexpr T bit_floor(T x) noexcept;
```

Constraints: **T** is an unsigned integer type (6.8.2).

Returns: If **x** == 0, 0; otherwise the maximal value **y** such that `has_single_bit(y)` is `true` and **y** <= **x**.

```
template<class T>
constexpr int bit_width(T x) noexcept;
```

Constraints: **T** is an unsigned integer type (6.8.2).

Returns: If **x** == 0, 0; otherwise one plus the base-2 logarithm of **x**, with any fractional part discarded.

22.15.6 `Rotating`

[`bit.rotate`]

In the following descriptions, let *N* denote `numeric_limits<T>::digits`.

```
template<class T>
[[nodiscard]] constexpr T rotl(T x, int s) noexcept;
    Constraints: T is an unsigned integer type (6.8.2).
    Let r be s % N.
    Returns: If r is 0, x; if r is positive, (x << r) | (x >> (N - r)); if r is negative, rotr(x, -r).
```

```
template<class T>
[[nodiscard]] constexpr T rotr(T x, int s) noexcept;
    Constraints: T is an unsigned integer type (6.8.2).
    Let r be s % N.
    Returns: If r is 0, x; if r is positive, (x >> r) | (x << (N - r)); if r is negative, rotl(x, -r).
```

22.15.7 Counting

[bit.count]

In the following descriptions, let N denote `numeric_limits<T>::digits`.

```
template<class T>
constexpr int countl_zero(T x) noexcept;
    Constraints: T is an unsigned integer type (6.8.2).
    Returns: The number of consecutive 0 bits in the value of x, starting from the most significant bit.
    NOTE 1 Returns N if x == 0.
```

```
template<class T>
constexpr int countl_one(T x) noexcept;
    Constraints: T is an unsigned integer type (6.8.2).
    Returns: The number of consecutive 1 bits in the value of x, starting from the most significant bit.
    NOTE 2 Returns N if x == numeric_limits<T>::max().
```

```
template<class T>
constexpr int countr_zero(T x) noexcept;
    Constraints: T is an unsigned integer type (6.8.2).
    Returns: The number of consecutive 0 bits in the value of x, starting from the least significant bit.
    NOTE 3 Returns N if x == 0.
```

```
template<class T>
constexpr int countr_one(T x) noexcept;
    Constraints: T is an unsigned integer type (6.8.2).
    Returns: The number of consecutive 1 bits in the value of x, starting from the least significant bit.
    NOTE 4 Returns N if x == numeric_limits<T>::max().
```

```
template<class T>
constexpr int popcount(T x) noexcept;
    Constraints: T is an unsigned integer type (6.8.2).
    Returns: The number of 1 bits in the value of x.
```

22.15.8 Endian

[bit.endian]

Two common methods of byte ordering in multibyte scalar types are big-endian and little-endian in the execution environment. Big-endian is a format for storage of binary data in which the most significant byte is placed first, with the rest in descending order. Little-endian is a format for storage of binary data in which the least significant byte is placed first, with the rest in ascending order. This subclause describes the endianness of the scalar types of the execution environment.

```
enum class endian {  
    little = see below,  
    big    = see below,  
    native = see below  
};
```

If all scalar types have size 1 byte, then all of `endian::little`, `endian::big`, and `endian::native` have the same value. Otherwise, `endian::little` is not equal to `endian::big`. If all scalar types are big-endian, `endian::native` is equal to `endian::big`. If all scalar types are little-endian, `endian::native` is equal to `endian::little`. Otherwise, `endian::native` is not equal to either `endian::big` or `endian::little`.

STANDARDSISO.COM : Click to view the full PDF of ISO/IEC 14882:2024

23 Strings library

[strings]

23.1 General

[strings.general]

This Clause describes components for manipulating sequences of any non-array trivial standard-layout (6.8.1) type. Such types are called *char-like types*, and objects of char-like types are called *char-like objects* or simply *characters*.

The following subclauses describe a character traits class, string classes, and null-terminated sequence utilities, as summarized in Table 78.

Table 78 — Strings library summary [tab:strings.summary]

Subclause	Header
23.2 Character traits	<string>
23.3 String view classes	<string_view>
23.4 String classes	<string>
23.5 Null-terminated sequence utilities	<cctype>, <cstdlib>, <cstring>, <cuchar>, <wchar>, <cwctype>

23.2 Character traits

[char.traits]

23.2.1 General

[char.traits.general]

Subclause 23.2 defines requirements on classes representing *character traits*, and defines a class template `char_traits<charT>`, along with five specializations, `char_traits<char>`, `char_traits<char8_t>`, `char_traits<char16_t>`, `char_traits<char32_t>`, and `char_traits<wchar_t>`, that meet those requirements.

Most classes specified in 23.4, 23.3, and Clause 31 need a set of related types and functions to complete the definition of their semantics. These types and functions are provided as a set of member *typedef-names* and functions in the template parameter `traits` used by each such template. Subclause 23.2 defines the semantics of these members.

To specialize those templates to generate a string, string view, or iostream class to handle a particular character container type (3.10) `C`, that and its related character traits class `X` are passed as a pair of parameters to the string, string view, or iostream template as parameters `charT` and `traits`. If `X::char_type` is not the same type as `C`, the program is ill-formed.

23.2.2 Character traits requirements

[char.traits.require]

In Table 79, `X` denotes a traits class defining types and functions for the character container type `C`; `c` and `d` denote values of type `C`; `p` and `q` denote values of type `const C*`; `s` denotes a value of type `C*`; `n`, `i` and `j` denote values of type `size_t`; `e` and `f` denote values of type `X::int_type`; `pos` denotes a value of type `X::pos_type`; and `r` denotes an lvalue of type `C`. No expression which is part of the character traits requirements specified in 23.2.2 shall exit via an exception.

Table 79 — Character traits requirements [tab:char.traits.req]

Expression	Return type	Assertion/note pre-/post-condition	Complexity
<code>X::char_type</code>	<code>C</code>		compile-time
<code>X::int_type</code>		(described in 23.2.3)	compile-time
<code>X::off_type</code>		(described in 31.2.3 and 31.3)	compile-time
<code>X::pos_type</code>		(described in 31.2.3 and 31.3)	compile-time
<code>X::state_type</code>		(described in 23.2.3)	compile-time
<code>X::eq(c,d)</code>	<code>bool</code>	Returns: whether <code>c</code> is to be treated as equal to <code>d</code> .	constant

Table 79 — Character traits requirements (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
<code>X::lt(c,d)</code>	<code>bool</code>	<i>Returns:</i> whether <code>c</code> is to be treated as less than <code>d</code> .	constant
<code>X::compare(p,q,n)</code>	<code>int</code>	<i>Returns:</i> 0 if for each <code>i</code> in <code>[0,n)</code> , <code>X::eq(p[i],q[i])</code> is <code>true</code> ; else, a negative value if, for some <code>j</code> in <code>[0,n)</code> , <code>X::lt(p[j],q[j])</code> is <code>true</code> and for each <code>i</code> in <code>[0,j)</code> <code>X::eq(p[i],q[i])</code> is <code>true</code> ; else a positive value.	linear
<code>X::length(p)</code>	<code>size_t</code>	<i>Returns:</i> the smallest <code>i</code> such that <code>X::eq(p[i],charT())</code> is <code>true</code> .	linear
<code>X::find(p,n,c)</code>	<code>const X::char_type*</code>	<i>Returns:</i> the smallest <code>q</code> in <code>[p,p+n)</code> such that <code>X::eq(*q,c)</code> is <code>true</code> , <code>nullptr</code> otherwise.	linear
<code>X::move(s,p,n)</code>	<code>X::char_type*</code>	for each <code>i</code> in <code>[0,n)</code> , performs <code>X::assign(s[i],p[i])</code> . Copies correctly even where the ranges <code>[p,p+n)</code> and <code>[s,s+n)</code> overlap. <i>Returns:</i> <code>s</code> .	linear
<code>X::copy(s,p,n)</code>	<code>X::char_type*</code>	<i>Preconditions:</i> The ranges <code>[p,p+n)</code> and <code>[s,s+n)</code> do not overlap. <i>Returns:</i> <code>s</code> . for each <code>i</code> in <code>[0,n)</code> , performs <code>X::assign(s[i],p[i])</code> .	linear
<code>X::assign(r,d)</code>	(not used)	assigns <code>r=d</code> .	constant
<code>X::assign(s,n,c)</code>	<code>X::char_type*</code>	for each <code>i</code> in <code>[0,n)</code> , performs <code>X::assign(s[i],c)</code> . <i>Returns:</i> <code>s</code> .	linear
<code>X::not_eof(e)</code>	<code>int_type</code>	<i>Returns:</i> <code>e</code> if <code>X::eq_int_type(e,X::eof())</code> is <code>false</code> , otherwise a value <code>f</code> such that <code>X::eq_int_type(f,X::eof())</code> is <code>false</code> .	constant
<code>X::to_char_type(e)</code>	<code>X::char_type</code>	<i>Returns:</i> if for some <code>c</code> , <code>X::eq_int_type(e,X::to_int_type(c))</code> is <code>true</code> , <code>c</code> ; else some unspecified value.	constant
<code>X::to_int_type(c)</code>	<code>X::int_type</code>	<i>Returns:</i> some value <code>e</code> , constrained by the definitions of <code>to_char_type</code> and <code>eq_int_type</code> .	constant

Table 79 — Character traits requirements (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
<code>X::eq_int_type(e,f)</code>	<code>bool</code>	<i>Returns:</i> for all <code>c</code> and <code>d</code> , <code>X::eq(c,d)</code> is equal to <code>X::eq_- int_type(X::to_int_type(c), X::to_int_type(d))</code> ; otherwise, yields <code>true</code> if <code>e</code> and <code>f</code> are both copies of <code>X::eof()</code> ; otherwise, yields <code>false</code> if one of <code>e</code> and <code>f</code> is a copy of <code>X::eof()</code> and the other is not; otherwise the value is unspecified.	constant
<code>X::eof()</code>	<code>X::int_type</code>	<i>Returns:</i> a value <code>e</code> such that <code>X::eq_int_type(e,X::to_- int_type(c))</code> is <code>false</code> for all values <code>c</code> .	constant

The class template

```
template<class charT> struct char_traits;
```

is provided in the header `<string>` as a basis for explicit specializations.

23.2.3 Traits typedefs

[char.traits.typedefs]

using `int_type` = *see below*;

Preconditions: `int_type` shall be able to represent all of the valid characters converted from the corresponding `char_type` values, as well as an end-of-file value, `eof()`.²⁰⁵

using `state_type` = *see below*;

Preconditions: `state_type` meets the *Cpp17Destructible* (Table 35), *Cpp17CopyAssignable* (Table 34), *Cpp17CopyConstructible* (Table 32), and *Cpp17DefaultConstructible* (Table 30) requirements.

23.2.4 char_traits specializations

[char.traits.specializations]

23.2.4.1 General

[char.traits.specializations.general]

```
namespace std {
    template<> struct char_traits<char>;
    template<> struct char_traits<char8_t>;
    template<> struct char_traits<char16_t>;
    template<> struct char_traits<char32_t>;
    template<> struct char_traits<wchar_t>;
}
```

The header `<string>` defines five specializations of the class template `char_traits`: `char_traits<char>`, `char_traits<char8_t>`, `char_traits<char16_t>`, `char_traits<char32_t>`, and `char_traits<wchar_t>`.

23.2.4.2 struct char_traits<char>

[char.traits.specializations.char]

```
namespace std {
    template<> struct char_traits<char> {
        using char_type = char;
        using int_type = int;
        using off_type = streamoff;
        using pos_type = streampos;
        using state_type = mbstate_t;
        using comparison_category = strong_ordering;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
```

²⁰⁵ If `eof()` can be held in `char_type` then some iostreams operations can give surprising results.

```

static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
static constexpr size_t length(const char_type* s);
static constexpr const char_type* find(const char_type* s, size_t n,
                                       const char_type& a);

static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
static constexpr char_type* assign(char_type* s, size_t n, char_type a);

static constexpr int_type not_eof(int_type c) noexcept;
static constexpr char_type to_char_type(int_type c) noexcept;
static constexpr int_type to_int_type(char_type c) noexcept;
static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
static constexpr int_type eof() noexcept;
};
}

```

The type `mbstate_t` is defined in `<wchar>` and can represent any of the conversion states that can occur in an implementation-defined set of supported multibyte character encoding rules.

The two-argument member `assign` is defined identically to the built-in operator `=`. The two-argument members `eq` and `lt` are defined identically to the built-in operators `==` and `<` for type `unsigned char`.

The member `eof()` returns EOF.

23.2.4.3 struct `char_traits<char8_t>` [`char.traits.specializations.char8.t`]

```

namespace std {
    template<> struct char_traits<char8_t> {
        using char_type = char8_t;
        using int_type = unsigned int;
        using off_type = streamoff;
        using pos_type = u8streampos;
        using state_type = mbstate_t;
        using comparison_category = strong_ordering;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;

        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n,
                                              const char_type& a);

        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
}

```

The two-argument members `assign`, `eq`, and `lt` are defined identically to the built-in operators `=`, `==`, and `<` respectively.

The member `eof()` returns an implementation-defined constant that cannot appear as a valid UTF-8 code unit.

23.2.4.4 struct `char_traits<char16_t>` [`char.traits.specializations.char16.t`]

```

namespace std {
    template<> struct char_traits<char16_t> {
        using char_type = char16_t;
        using int_type = uint_least16_t;
        using off_type = streamoff;
        using pos_type = u16streampos;
    };
}

```

```

using state_type = mbstate_t;
using comparison_category = strong_ordering;

static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
static constexpr bool eq(char_type c1, char_type c2) noexcept;
static constexpr bool lt(char_type c1, char_type c2) noexcept;

static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
static constexpr size_t length(const char_type* s);
static constexpr const char_type* find(const char_type* s, size_t n,
                                       const char_type& a);
static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
static constexpr char_type* assign(char_type* s, size_t n, char_type a);

static constexpr int_type not_eof(int_type c) noexcept;
static constexpr char_type to_char_type(int_type c) noexcept;
static constexpr int_type to_int_type(char_type c) noexcept;
static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
static constexpr int_type eof() noexcept;
};
}

```

The two-argument members `assign`, `eq`, and `lt` are defined identically to the built-in operators `=`, `==`, and `<`, respectively.

The member `eof()` returns an implementation-defined constant that cannot appear as a valid UTF-16 code unit.

23.2.4.5 struct `char_traits<char32_t>`

[`char.traits.specializations.char32.t`]

```

namespace std {
    template<> struct char_traits<char32_t> {
        using char_type = char32_t;
        using int_type = uint_least32_t;
        using off_type = streamoff;
        using pos_type = u32streampos;
        using state_type = mbstate_t;
        using comparison_category = strong_ordering;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;

        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n,
                                              const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);

        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
}

```

The two-argument members `assign`, `eq`, and `lt` are defined identically to the built-in operators `=`, `==`, and `<`, respectively.

The member `eof()` returns an implementation-defined constant that cannot appear as a Unicode code point.

23.2.4.6 struct char_traits<wchar_t>**[char.traits.specializations.wchar.t]**

```

namespace std {
    template<> struct char_traits<wchar_t> {
        using char_type = wchar_t;
        using int_type = wint_t;
        using off_type = streamoff;
        using pos_type = wstreampos;
        using state_type = mbstate_t;
        using comparison_category = strong_ordering;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;

        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n,
                                              const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);

        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
}

```

The two-argument members `assign`, `eq`, and `lt` are defined identically to the built-in operators `=`, `==`, and `<`, respectively.

The member `eof()` returns `WEOF`.

23.3 String view classes**[string.view]****23.3.1 General****[string.view.general]**

The class template `basic_string_view` describes an object that can refer to a constant contiguous sequence of char-like (23.1) objects with the first element of the sequence at position zero. In the rest of 23.3, the type of the char-like objects held in a `basic_string_view` object is designated by `charT`.

NOTE The library provides implicit conversions from `const charT*` and `std::basic_string<charT, ...>` to `std::basic_string_view<charT, ...>` so that user code can accept just `std::basic_string_view<charT>` as a non-templated parameter wherever a sequence of characters is expected. User-defined types can define their own implicit conversions to `std::basic_string_view<charT>` in order to interoperate with these functions.

23.3.2 Header <string_view> synopsis**[string.view.synop]**

```

#include <compare> // see 17.11.1

namespace std {
    // 23.3.3, class template basic_string_view
    template<class charT, class traits = char_traits<charT>>
    class basic_string_view;

    template<class charT, class traits>
        constexpr bool ranges::enable_view<basic_string_view<charT, traits>> = true;
    template<class charT, class traits>
        constexpr bool ranges::enable_borrowed_range<basic_string_view<charT, traits>> = true;

    // 23.3.4, non-member comparison functions
    template<class charT, class traits>
        constexpr bool operator==(basic_string_view<charT, traits> x,
                                   basic_string_view<charT, traits> y) noexcept;
}

```

```

template<class charT, class traits>
constexpr see below operator<=>(basic_string_view<charT, traits> x,
                                basic_string_view<charT, traits> y) noexcept;

// see 23.3.4, sufficient additional overloads of comparison functions

// 23.3.5, inserters and extractors
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<((basic_ostream<charT, traits>& os,
          basic_string_view<charT, traits> str);

// basic_string_view typedef-names
using string_view    = basic_string_view<char>;
using u8string_view  = basic_string_view<char8_t>;
using u16string_view = basic_string_view<char16_t>;
using u32string_view = basic_string_view<char32_t>;
using wstring_view   = basic_string_view<wchar_t>;

// 23.3.6, hash support
template<class T> struct hash;
template<> struct hash<string_view>;
template<> struct hash<u8string_view>;
template<> struct hash<u16string_view>;
template<> struct hash<u32string_view>;
template<> struct hash<wstring_view>;

inline namespace literals {
inline namespace string_view_literals {
    // 23.3.7, suffix for basic_string_view literals
    constexpr string_view operator""sv(const char* str, size_t len) noexcept;
    constexpr u8string_view operator""sv(const char8_t* str, size_t len) noexcept;
    constexpr u16string_view operator""sv(const char16_t* str, size_t len) noexcept;
    constexpr u32string_view operator""sv(const char32_t* str, size_t len) noexcept;
    constexpr wstring_view operator""sv(const wchar_t* str, size_t len) noexcept;
}
}
}

```

The function templates defined in 22.2.2 and 25.7 are available when `<string_view>` is included.

23.3.3 Class template `basic_string_view`

[string.view.template]

23.3.3.1 General

[string.view.template.general]

```

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_string_view {
    public:
        // types
        using traits_type      = traits;
        using value_type       = charT;
        using pointer          = value_type*;
        using const_pointer    = const value_type*;
        using reference        = value_type&;
        using const_reference  = const value_type&;
        using const_iterator   = implementation-defined; // see 23.3.3.4
        using iterator         = const_iterator;206
        using const_reverse_iterator = reverse_iterator<const_iterator>;
        using reverse_iterator   = const_reverse_iterator;
        using size_type          = size_t;
        using difference_type    = ptrdiff_t;
        static constexpr size_type npos = size_type(-1);
    };
}

```

²⁰⁶) Because `basic_string_view` refers to a constant sequence, `iterator` and `const_iterator` are the same type.

```

// 23.3.3.2, construction and assignment
constexpr basic_string_view() noexcept;
constexpr basic_string_view(const basic_string_view&) noexcept = default;

constexpr size_type find_last_not_of(charT c, size_type pos = npos) const noexcept;
constexpr size_type find_last_not_of(const charT* s, size_type pos,
                                     size_type n) const;
constexpr size_type find_last_not_of(const charT* s, size_type pos = npos) const;

private:
    const_pointer data_;           // exposition only
    size_type size_;              // exposition only
};

// 23.3.3.3, deduction guides
template<class It, class End>
    basic_string_view(It, End) -> basic_string_view<iter_value_t<It>>;
template<class R>
    basic_string_view(R&&) -> basic_string_view<ranges::range_value_t<R>>;
}

```

In every specialization `basic_string_view<charT, traits>`, the type `traits` shall meet the character traits requirements (23.2).

NOTE The program is ill-formed if `traits::char_type` is not the same type as `charT`.

For a `basic_string_view str`, any operation that invalidates a pointer in the range

`[str.data(), str.data() + str.size())`

invalidates pointers, iterators, and references returned from `str`'s member functions.

The complexity of `basic_string_view` member functions is $\mathcal{O}(1)$ unless otherwise specified.

`basic_string_view<charT, traits>` is a trivially copyable type (6.8.1).

23.3.3.2 Construction and assignment

[string.view.cons]

```
constexpr basic_string_view() noexcept;
```

Postconditions: `size_ == 0` and `data_ == nullptr`.

```
constexpr basic_string_view(const charT* str);
```

Preconditions: `[str, str + traits::length(str))` is a valid range.

Effects: Constructs a `basic_string_view`, initializing `data_` with `str` and initializing `size_` with `traits::length(str)`.

Complexity: $\mathcal{O}(\text{traits}::\text{length}(\text{str}))$.

```
constexpr basic_string_view(const charT* str, size_type len);
```

Preconditions: `[str, str + len)` is a valid range.

Effects: Constructs a `basic_string_view`, initializing `data_` with `str` and initializing `size_` with `len`.

```
template<class It, class End>
constexpr basic_string_view(It begin, End end);
```

Constraints:

- It satisfies `contiguous_iterator`.
- End satisfies `sized_sentinel_for<It>`.
- `is_same_v<iter_value_t<It>, charT>` is true.
- `is_convertible_v<End, size_type>` is false.

Preconditions:

- `[begin, end)` is a valid range.
- It models `contiguous_iterator`.
- End models `sized_sentinel_for<It>`.

Effects: Initializes `data_` with `to_address(begin)` and initializes `size_` with `end - begin`.

Throws: When and what `end - begin` throws.

```
template<class R>
constexpr explicit basic_string_view(R&& r);

Let d be an lvalue of type remove_cvref_t<R>.
```

Constraints:

- `remove_cvref_t<R>` is not the same type as `basic_string_view`,
- R models `ranges::contiguous_range` and `ranges::sized_range`,
- `is_same_v<ranges::range_value_t<R>, charT>` is true,
- `is_convertible_v<R, const charT*>` is false, and
- `d.operator::std::basic_string_view<charT, traits>()` is not a valid expression.

Effects: Initializes `data_` with `ranges::data(r)` and `size_` with `ranges::size(r)`.

Throws: Any exception thrown by `ranges::data(r)` and `ranges::size(r)`.

23.3.3.3 Deduction guides

[string.view.deduct]

```
template<class It, class End>
basic_string_view(It, End) -> basic_string_view<iter_value_t<It>>;
```

Constraints:

- It satisfies `contiguous_iterator`.
- End satisfies `sized_sentinel_for<It>`.

```
template<class R>
basic_string_view(R&&) -> basic_string_view<ranges::range_value_t<R>>;
```

Constraints: R satisfies `ranges::contiguous_range`.

23.3.3.4 Iterator support

[string.view.iterators]

```
using const_iterator = implementation-defined;
```

A type that meets the requirements of a constant *Cpp17RandomAccessIterator* (25.3.5.7), models `contiguous_iterator` (25.3.4.14), and meets the `constexpr` iterator requirements (25.3.1), whose `value_type` is the template parameter `charT`.

All requirements on container iterators (24.2) apply to `basic_string_view::const_iterator` as well.

```
constexpr const_iterator begin() const noexcept;
constexpr const_iterator cbegin() const noexcept;
```

Returns: An iterator such that

- if `!empty()`, `addressof(*begin()) == data_`,
- otherwise, an unspecified value such that `[begin(), end())` is a valid range.

```
constexpr const_iterator end() const noexcept;
constexpr const_iterator cend() const noexcept;
```

Returns: `begin() + size()`.

```
constexpr const_reverse_iterator rbegin() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;
```

Returns: `const_reverse_iterator(end())`.

```
constexpr const_reverse_iterator rend() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;
```

Returns: `const_reverse_iterator(begin())`.

23.3.3.5 Capacity

[string.view.capacity]

```
constexpr size_type size() const noexcept;
constexpr size_type length() const noexcept;
```

Returns: `size_`.

```
constexpr size_type max_size() const noexcept;
```

Returns: The largest possible number of char-like objects that can be referred to by a `basic_string_view`.

```
[[nodiscard]] constexpr bool empty() const noexcept;
```

Returns: `size_ == 0`.

23.3.3.6 Element access

[string.view.access]

```
constexpr const_reference operator[](size_type pos) const;
```

Preconditions: `pos < size()`.

Returns: `data_[pos]`.

Throws: Nothing.

NOTE 1 Unlike `basic_string::operator[]`, `basic_string_view::operator[](size())` has undefined behavior instead of returning `charT()`.

```
constexpr const_reference at(size_type pos) const;
```

Returns: `data_[pos]`.

Throws: `out_of_range` if `pos >= size()`.

```
constexpr const_reference front() const;
```

Preconditions: `!empty()`.

Returns: `data_[0]`.

Throws: Nothing.

```
constexpr const_reference back() const;
```

Preconditions: `!empty()`.

Returns: `data_[size() - 1]`.

Throws: Nothing.

```
constexpr const_pointer data() const noexcept;
```

Returns: `data_`.

NOTE 2 Unlike `basic_string::data()` and *string-literals*, `data()` can return a pointer to a buffer that is not null-terminated. Therefore it is typically a mistake to pass `data()` to a function that takes just a `const char*` and expects a null-terminated string.

23.3.3.7 Modifiers

[string.view.modifiers]

```
constexpr void remove_prefix(size_type n);
```

Preconditions: `n <= size()`.

Effects: Equivalent to: `data_ += n; size_ -= n;`

```
constexpr void remove_suffix(size_type n);
```

Preconditions: `n <= size()`.

Effects: Equivalent to: `size_ -= n;`

```
constexpr void swap(basic_string_view& s) noexcept;
```

Effects: Exchanges the values of `*this` and `s`.

23.3.3.8 String operations

[string.view.ops]

```
constexpr size_type copy(charT* s, size_type n, size_type pos = 0) const;
```

Let `rlen` be the smaller of `n` and `size() - pos`.

Preconditions: `[s, s + rlen)` is a valid range.

Effects: Equivalent to `traits::copy(s, data() + pos, rlen)`.

Returns: `rlen`.

Throws: `out_of_range` if `pos > size()`.

Complexity: $\mathcal{O}(\text{rlen})$.

```
constexpr basic_string_view substr(size_type pos = 0, size_type n = npos) const;
```

Let `rlen` be the smaller of `n` and `size() - pos`.

Effects: Determines `rlen`, the effective length of the string to reference.

Returns: `basic_string_view(data() + pos, rlen)`.

Throws: `out_of_range` if `pos > size()`.

```
constexpr int compare(basic_string_view str) const noexcept;
```

Let `rlen` be the smaller of `size()` and `str.size()`.

Effects: Determines `rlen`, the effective length of the strings to compare. The function then compares the two strings by calling `traits::compare(data(), str.data(), rlen)`.

Returns: The nonzero result if the result of the comparison is nonzero. Otherwise, returns a value as indicated in Table 80.

Table 80 — `compare()` results [tab:string.view.compare]

Condition	Return Value
<code>size() < str.size()</code>	<code>< 0</code>
<code>size() == str.size()</code>	<code>0</code>
<code>size() > str.size()</code>	<code>> 0</code>

Complexity: $\mathcal{O}(\text{rlen})$.

```
constexpr int compare(size_type pos1, size_type n1, basic_string_view str) const;
```

Effects: Equivalent to: `return substr(pos1, n1).compare(str);`

```
constexpr int compare(size_type pos1, size_type n1, basic_string_view str,
                      size_type pos2, size_type n2) const;
```

Effects: Equivalent to: `return substr(pos1, n1).compare(str.substr(pos2, n2));`

```
constexpr int compare(const charT* s) const;
```

Effects: Equivalent to: `return compare(basic_string_view(s));`

```
constexpr int compare(size_type pos1, size_type n1, const charT* s) const;
```

Effects: Equivalent to: `return substr(pos1, n1).compare(basic_string_view(s));`

```
constexpr int compare(size_type pos1, size_type n1, const charT* s, size_type n2) const;
```

Effects: Equivalent to: `return substr(pos1, n1).compare(basic_string_view(s, n2));`

```
constexpr bool starts_with(basic_string_view x) const noexcept;
```

Effects: Equivalent to: `return substr(0, x.size()) == x;`

```
constexpr bool starts_with(charT x) const noexcept;
```

Effects: Equivalent to: `return !empty() && traits::eq(front(), x);`

```
constexpr bool starts_with(const charT* x) const;
```

Effects: Equivalent to: `return starts_with(basic_string_view(x));`

```
constexpr bool ends_with(basic_string_view x) const noexcept;
```

Effects: Equivalent to:

```
return size() >= x.size() && compare(size() - x.size(), npos, x) == 0;
```

```
constexpr bool ends_with(charT x) const noexcept;
```

Effects: Equivalent to: `return !empty() && traits::eq(back(), x);`

```
constexpr bool ends_with(const charT* x) const;
```

Effects: Equivalent to: `return ends_with(basic_string_view(x));`

```
constexpr bool contains(basic_string_view x) const noexcept;
```

```
constexpr bool contains(charT x) const noexcept;
```

```
constexpr bool contains(const charT* x) const;
```

Effects: Equivalent to: `return find(x) != npos;`

23.3.3.9 Searching

[string.view.find]

Member functions in this subclause have complexity $\mathcal{O}(\text{size()} * \text{str.size}())$ at worst, although implementations should do better.

Let F be one of `find`, `rfind`, `find_first_of`, `find_last_of`, `find_first_not_of`, and `find_last_not_of`.

- Each member function of the form

```
constexpr return-type F(const charT* s, size_type pos) const;
```

has effects equivalent to: `return F(basic_string_view(s), pos);`

- Each member function of the form

```
constexpr return-type F(const charT* s, size_type pos, size_type n) const;
```

has effects equivalent to: `return F(basic_string_view(s, n), pos);`

- Each member function of the form

```
constexpr return-type F(charT c, size_type pos) const noexcept;
```

has effects equivalent to: `return F(basic_string_view(addressof(c), 1), pos);`

```
constexpr size_type find(basic_string_view str, size_type pos = 0) const noexcept;
```

Let $xpos$ be the lowest position, if possible, such that the following conditions hold:

- $pos \leq xpos$
- $xpos + \text{str.size}() \leq \text{size}()$
- `traits::eq(at(xpos + I), str.at(I))` for all elements I of the string referenced by `str`.

Effects: Determines `xpos`.

Returns: `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.

```
constexpr size_type rfind(basic_string_view str, size_type pos = npos) const noexcept;
```

Let `xpos` be the highest position, if possible, such that the following conditions hold:

- `xpos <= pos`
- `xpos + str.size() <= size()`
- `traits::eq(at(xpos + I), str.at(I))` for all elements `I` of the string referenced by `str`.

Effects: Determines `xpos`.

Returns: `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.

```
constexpr size_type find_first_of(basic_string_view str, size_type pos = 0) const noexcept;
```

Let `xpos` be the lowest position, if possible, such that the following conditions hold:

- `pos <= xpos`
- `xpos < size()`
- `traits::eq(at(xpos), str.at(I))` for some element `I` of the string referenced by `str`.

Effects: Determines `xpos`.

Returns: `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.

```
constexpr size_type find_last_of(basic_string_view str, size_type pos = npos) const noexcept;
```

Let `xpos` be the highest position, if possible, such that the following conditions hold:

- `xpos <= pos`
- `xpos < size()`
- `traits::eq(at(xpos), str.at(I))` for some element `I` of the string referenced by `str`.

Effects: Determines `xpos`.

Returns: `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.

```
constexpr size_type find_first_not_of(basic_string_view str, size_type pos = 0) const noexcept;
```

Let `xpos` be the lowest position, if possible, such that the following conditions hold:

- `pos <= xpos`
- `xpos < size()`
- `traits::eq(at(xpos), str.at(I))` for no element `I` of the string referenced by `str`.

Effects: Determines `xpos`.

Returns: `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.

```
constexpr size_type find_last_not_of(basic_string_view str, size_type pos = npos) const noexcept;
```

Let `xpos` be the highest position, if possible, such that the following conditions hold:

- `xpos <= pos`
- `xpos < size()`
- `traits::eq(at(xpos), str.at(I))` for no element `I` of the string referenced by `str`.

Effects: Determines `xpos`.

Returns: `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.

23.3.4 Non-member comparison functions

[string.view.comparison]

Let `S` be `basic_string_view<charT, traits>`, and `sv` be an instance of `S`. Implementations shall provide sufficient additional overloads marked `constexpr` and `noexcept` so that an object `t` with an implicit conversion to `S` can be compared according to [Table 81](#).

Table 81 — Additional `basic_string_view` comparison overloads
[tab:string.view.comparison.overloads]

Expression	Equivalent to
<code>t == sv</code>	<code>S(t) == sv</code>
<code>sv == t</code>	<code>sv == S(t)</code>
<code>t != sv</code>	<code>S(t) != sv</code>
<code>sv != t</code>	<code>sv != S(t)</code>
<code>t < sv</code>	<code>S(t) < sv</code>
<code>sv < t</code>	<code>sv < S(t)</code>
<code>t > sv</code>	<code>S(t) > sv</code>
<code>sv > t</code>	<code>sv > S(t)</code>
<code>t <= sv</code>	<code>S(t) <= sv</code>
<code>sv <= t</code>	<code>sv <= S(t)</code>
<code>t >= sv</code>	<code>S(t) >= sv</code>
<code>sv >= t</code>	<code>sv >= S(t)</code>
<code>t <=> sv</code>	<code>S(t) <=> sv</code>
<code>sv <=> t</code>	<code>sv <=> S(t)</code>

EXAMPLE A sample conforming implementation for `operator==` would be:

```
template<class charT, class traits>
constexpr bool operator==(basic_string_view<charT, traits> lhs,
                          basic_string_view<charT, traits> rhs) noexcept {
    return lhs.compare(rhs) == 0;
}
template<class charT, class traits>
constexpr bool operator==(basic_string_view<charT, traits> lhs,
                          type_identity_t<basic_string_view<charT, traits>> rhs) noexcept {
    return lhs.compare(rhs) == 0;
}
```

```
template<class charT, class traits>
constexpr bool operator==(basic_string_view<charT, traits> lhs,
                          basic_string_view<charT, traits> rhs) noexcept;
```

Returns: `lhs.compare(rhs) == 0`.

```
template<class charT, class traits>
constexpr see below operator<=>(basic_string_view<charT, traits> lhs,
                                basic_string_view<charT, traits> rhs) noexcept;
```

Let `R` denote the type `traits::comparison_category` if that *qualified-id* is valid and denotes a type (13.10.3), otherwise `R` is `weak_ordering`.

Mandates: `R` denotes a comparison category type (17.11.2).

Returns: `static_cast<R>(lhs.compare(rhs) <=> 0)`.

23.3.5 Inserters and extractors

[string.view.io]

```
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, basic_string_view<charT, traits> str);
```

Effects: Behaves as a formatted output function (31.7.6.3.1) of `os`. Forms a character sequence `seq`, initially consisting of the elements defined by the range `[str.begin(), str.end())`. Determines padding for `seq` as described in 31.7.6.3.1. Then inserts `seq` as if by calling `os.rdbuf()->sputn(seq, n)`, where `n` is the larger of `os.width()` and `str.size()`; then calls `os.width(0)`.

Returns: `os`

23.3.6 Hash support

[string.view.hash]

```
template<> struct hash<string_view>;
```

```
template<> struct hash<u8string_view>;
template<> struct hash<u16string_view>;
template<> struct hash<u32string_view>;
template<> struct hash<wstring_view>;
```

The specialization is enabled (22.10.19).

NOTE The hash value of a string view object is equal to the hash value of the corresponding string object (23.4.6).

23.3.7 Suffix for basic_string_view literals

[string.view.literals]

```
constexpr string_view operator""sv(const char* str, size_t len) noexcept;
```

Returns: string_view{str, len}.

```
constexpr u8string_view operator""sv(const char8_t* str, size_t len) noexcept;
```

Returns: u8string_view{str, len}.

```
constexpr u16string_view operator""sv(const char16_t* str, size_t len) noexcept;
```

Returns: u16string_view{str, len}.

```
constexpr u32string_view operator""sv(const char32_t* str, size_t len) noexcept;
```

Returns: u32string_view{str, len}.

```
constexpr wstring_view operator""sv(const wchar_t* str, size_t len) noexcept;
```

Returns: wstring_view{str, len}.

23.4 String classes

[string.classes]

23.4.1 General

[string.classes.general]

The header <string> defines the basic_string class template for manipulating varying-length sequences of char-like objects and five typedef-names, string, u8string, u16string, u32string, and wstring, that name the specializations basic_string<char>, basic_string<char8_t>, basic_string<char16_t>, basic_string<char32_t>, and basic_string<wchar_t>, respectively.

23.4.2 Header <string> synopsis

[string.syn]

```
#include <compare>           // see 17.11.1
#include <initializer_list>   // see 17.10.2

namespace std {
    // 23.2, character traits
    template<class charT> struct char_traits;
    template<> struct char_traits<char>;
    template<> struct char_traits<char8_t>;
    template<> struct char_traits<char16_t>;
    template<> struct char_traits<char32_t>;
    template<> struct char_traits<wchar_t>;

    // 23.4.2, basic_string
    template<class charT, class traits = char_traits<charT>, class Allocator = allocator<charT>>
        class basic_string;

    template<class charT, class traits, class Allocator>
        constexpr basic_string<charT, traits, Allocator>
            operator+(const basic_string<charT, traits, Allocator>& lhs,
                      const basic_string<charT, traits, Allocator>& rhs);
    template<class charT, class traits, class Allocator>
        constexpr basic_string<charT, traits, Allocator>
            operator+(basic_string<charT, traits, Allocator>&& lhs,
                      const basic_string<charT, traits, Allocator>& rhs);
    template<class charT, class traits, class Allocator>
        constexpr basic_string<charT, traits, Allocator>
            operator+(const basic_string<charT, traits, Allocator>& lhs,
                      basic_string<charT, traits, Allocator>&& rhs);
```

```

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs,
          basic_string<charT, traits, Allocator>&& rhs);
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>

23.4.3 Class template `basic_string`

[basic.string]

23.4.3.1 General

[basic.string.general]

The class template `basic_string` describes objects that can store a sequence consisting of a varying number of arbitrary char-like objects with the first element of the sequence at position zero. Such a sequence is also called a “string” if the type of the char-like objects that it holds is clear from context. In the rest of 23.4.3, the type of the char-like objects held in a `basic_string` object is designated by `charT`.

A specialization of `basic_string` is a contiguous container (24.2.2.2).

In all cases, `[data(), data() + size())` is a valid range, `data() + size()` points at an object with value `charT()` (a “null terminator”), and `size() <= capacity()` is true.

```

namespace std {
    template<class charT, class traits = char_traits<charT>,
            class Allocator = allocator<charT>>
        class basic_string {
        public:
            // types
            using traits_type      = traits;
            using value_type       = charT;
            using allocator_type   = Allocator;
            using size_type        = typename allocator_traits<Allocator>::size_type;

```

    -> basic_string<charT, traits, Allocator>;
}

```

A `size_type` parameter type in a `basic_string` deduction guide refers to the `size_type` member type of the type deduced by the deduction guide.

The types `iterator` and `const_iterator` meet the `constexpr` iterator requirements (25.3.1).

23.4.3.2 General requirements

[string.require]

If any operation would cause `size()` to exceed `max_size()`, that operation throws an exception object of type `length_error`.

If any member function or operator of `basic_string` throws an exception, that function or operator has no other effect on the `basic_string` object.

In every specialization `basic_string<charT, traits, Allocator>`, the type `allocator_traits<Allocator>::value_type` shall name the same type as `charT`. Every object of type `basic_string<charT,`

`traits`, `Allocator`> uses an object of type `Allocator` to allocate and free storage for the contained `charT` objects as needed. The `Allocator` object used is obtained as described in 24.2.2.2. In every specialization `basic_string<charT, traits, Allocator>`, the type `traits` shall meet the character traits requirements (23.2).

NOTE 1 Every specialization `basic_string<charT, traits, Allocator>` is an allocator-aware container, but does not use the allocator's `construct` and `destroy` member functions (24.2.1).

NOTE 2 The program is ill-formed if `traits::char_type` is not the same type as `charT`.

References, pointers, and iterators referring to the elements of a `basic_string` sequence may be invalidated by the following uses of that `basic_string` object:

- Passing as an argument to any standard library function taking a reference to non-const `basic_string` as an argument.²⁰⁷
- Calling non-const member functions, except `operator[]`, `at`, `data`, `front`, `back`, `begin`, `rbegin`, `end`, and `rend`.

23.4.3.3 Constructors and assignment operators

```
constexpr explicit basic_string(const Allocator& a) noexcept;
```

Postconditions: `size()` is equal to 0.

```
constexpr basic_string(const basic_string& str);
```

```
constexpr basic_string(basic_string&& str) noexcept;
```

Effects: Constructs an object whose value is that of `str` prior to this call.

Remarks: In the second form, `str` is left in a valid but unspecified state.

```
constexpr basic_string(const basic_string& str, size_type pos,
                      const Allocator& a = Allocator());
constexpr basic_string(const basic_string& str, size_type pos, size_type n,
                      const Allocator& a = Allocator());
constexpr basic_string(basic_string&& str, size_type pos,
                      const Allocator& a = Allocator());
constexpr basic_string(basic_string&& str, size_type pos, size_type n,
                      const Allocator& a = Allocator());
```

Let

- `s` be the value of `str` prior to this call and
- `rlen` be `pos + min(n, s.size() - pos)` for the overloads with parameter `n`, and `s.size()` otherwise.

Effects: Constructs an object whose initial value is the range `[s.data() + pos, s.data() + rlen)`.

Throws: `out_of_range` if `pos > s.size()`.

Remarks: For the overloads with a `basic_string&&` parameter, `str` is left in a valid but unspecified state.

Recommended practice: For the overloads with a `basic_string&&` parameter, implementations should avoid allocation if `s.get_allocator() == a` is true.

```
template<class T>
```

```
constexpr basic_string(const T& t, size_type pos, size_type n, const Allocator& a = Allocator());
```

Constraints: `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true.

Effects: Creates a variable, `sv`, as if by `basic_string_view<charT, traits> sv = t`; and then behaves the same as:

```
basic_string(sv.substr(pos, n), a);
```

```
template<class T>
```

```
constexpr explicit basic_string(const T& t, const Allocator& a = Allocator());
```

Constraints:

²⁰⁷ For example, as an argument to non-member functions `swap()` (23.4.4.3), `operator>>()` (23.4.4.4), and `getline()` (23.4.4.4), or as an argument to `basic_string::swap()`.

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Effects: Creates a variable, `sv`, as if by `basic_string_view<charT, traits> sv = t`; and then behaves the same as `basic_string(sv.data(), sv.size(), a)`.

```
constexpr basic_string(const charT* s, size_type n, const Allocator& a = Allocator());
```

Preconditions: `[s, s + n)` is a valid range.

Effects: Constructs an object whose initial value is the range `[s, s + n)`.

Postconditions: `size()` is equal to `n`, and `traits::compare(data(), s, n)` is equal to 0.

```
constexpr basic_string(const charT* s, const Allocator& a = Allocator());
```

Constraints: `Allocator` is a type

that qualifies as an allocator (24.2.2.2).

NOTE 1 This affects class template argument deduction.

Effects: Equivalent to: `basic_string(s, traits::length(s), a)`.

```
constexpr basic_string(size_type n, charT c, const Allocator& a = Allocator());
```

Constraints: `Allocator` is a type that qualifies as an allocator (24.2.2.2).

NOTE 2 This affects class template argument deduction.

Effects: Constructs an object whose value consists of `n` copies of `c`.

```
template<class InputIterator>
```

```
constexpr basic_string(InputIterator begin, InputIterator end, const Allocator& a = Allocator());
```

Constraints: `InputIterator` is a type that qualifies as an input iterator (24.2.2.2).

Effects: Constructs a string from the values in the range `[begin, end)`, as specified in 24.2.4.

```
template<container-compatible-range<charT> R>
```

```
constexpr basic_string(from_range_t, R&& rg, const Allocator& = Allocator());
```

Effects: Constructs a string from the values in the range `rg`, as specified in 24.2.4.

```
constexpr basic_string(initializer_list<charT> il, const Allocator& a = Allocator());
```

Effects: Equivalent to `basic_string(il.begin(), il.end(), a)`.

```
constexpr basic_string(const basic_string& str, const Allocator& alloc);
```

```
constexpr basic_string(basic_string&& str, const Allocator& alloc);
```

Effects: Constructs an object whose value is that of `str` prior to this call. The stored allocator is constructed from `alloc`. In the second form, `str` is left in a valid but unspecified state.

Throws: The second form throws nothing if `alloc == str.get_allocator()`.

```
template<class InputIterator,
```

```
class Allocator = allocator<typename iterator_traits<InputIterator>::value_type>>
```

```
basic_string(InputIterator, InputIterator, Allocator = Allocator())
```

```
-> basic_string<typename iterator_traits<InputIterator>::value_type,  
char_traits<typename iterator_traits<InputIterator>::value_type>,  
Allocator>;
```

Constraints: `InputIterator` is a type that qualifies as an input iterator, and `Allocator` is a type that qualifies as an allocator (24.2.2.2).

```
template<class charT,
```

```
class traits,
```

```
class Allocator = allocator<charT>>
```

```
explicit basic_string(basic_string_view<charT, traits>, const Allocator& = Allocator())
```

```
-> basic_string<charT, traits, Allocator>;
```

```
template<class charT,
        class traits,
        class Allocator = allocator<charT>>
basic_string(basic_string_view<charT, traits>,
            typename see below::size_type, typename see below::size_type,
            const Allocator& = Allocator())
-> basic_string<charT, traits, Allocator>;
```

Constraints: Allocator is a type that qualifies as an allocator (24.2.2.2).

```
constexpr basic_string& operator=(const basic_string& str);
```

Effects: If **this* and *str* are the same object, has no effect. Otherwise, replaces the value of **this* with a copy of *str*.

Returns: **this*.

```
constexpr basic_string& operator=(basic_string&& str)
noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
        allocator_traits<Allocator>::is_always_equal::value);
```

Effects: Move assigns as a sequence container (24.2.4), except that iterators, pointers and references may be invalidated.

Returns: **this*.

```
template<class T>
constexpr basic_string& operator=(const T& t);
```

Constraints:

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Effects: Equivalent to:

```
basic_string_view<charT, traits> sv = t;
return assign(sv);
```

```
constexpr basic_string& operator=(const charT* s);
```

Effects: Equivalent to: `return *this = basic_string_view<charT, traits>(s);`

```
constexpr basic_string& operator=(charT c);
```

Effects: Equivalent to:

```
return *this = basic_string_view<charT, traits>(addressof(c), 1);
```

```
constexpr basic_string& operator=(initializer_list<charT> il);
```

Effects: Equivalent to:

```
return *this = basic_string_view<charT, traits>(il.begin(), il.size());
```

23.4.3.4 Iterator support

[string.iterators]

```
constexpr iterator      begin() noexcept;
constexpr const_iterator begin() const noexcept;
constexpr const_iterator cbegin() const noexcept;
```

Returns: An iterator referring to the first character in the string.

```
constexpr iterator      end() noexcept;
constexpr const_iterator end() const noexcept;
constexpr const_iterator cend() const noexcept;
```

Returns: An iterator which is the past-the-end value.

```
constexpr reverse_iterator      rbegin() noexcept;
constexpr const_reverse_iterator rbegin() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;
```

Returns: An iterator which is semantically equivalent to `reverse_iterator(end())`.

```
constexpr reverse_iterator      rend() noexcept;
constexpr const_reverse_iterator rend() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;
```

Returns: An iterator which is semantically equivalent to `reverse_iterator(begin())`.

23.4.3.5 Capacity

[string.capacity]

```
constexpr size_type size() const noexcept;
constexpr size_type length() const noexcept;
```

Returns: A count of the number of char-like objects currently in the string.

Complexity: Constant time.

```
constexpr size_type max_size() const noexcept;
```

Returns: The largest possible number of char-like objects that can be stored in a `basic_string`.

Complexity: Constant time.

```
constexpr void resize(size_type n, charT c);
```

Effects: Alters the value of `*this` as follows:

- If `n <= size()`, erases the last `size() - n` elements.
- If `n > size()`, appends `n - size()` copies of `c`.

```
constexpr void resize(size_type n);
```

Effects: Equivalent to `resize(n, charT())`.

```
template<class Operation> constexpr void resize_and_overwrite(size_type n, Operation op);
```

Let

- `o = size()` before the call to `resize_and_overwrite`.
- `k` be `min(o, n)`.
- `p` be a value of type `charT*` or `charT* const`, such that the range `[p, p + n]` is valid and `this->compare(0, k, p, k) == 0` is true before the call. The values in the range `[p + k, p + n]` may be indeterminate (6.7.4).
- `m` be a value of type `size_type` or `const size_type` equal to `n`.
- `OP` be the expression `std::move(op)(p, m)`.
- `r = OP`.

Mandates: `OP` has an integer-like type (25.3.4.4).

Preconditions:

- `OP` does not throw an exception or modify `p` or `m`.
- `r ≥ 0`.
- `r ≤ m`.
- After evaluating `OP` there are no indeterminate values in the range `[p, p + r]`.

Effects: Evaluates `OP`, replaces the contents of `*this` with `[p, p + r]`, and invalidates all pointers and references to the range `[p, p + n]`.

Recommended practice: Implementations should avoid unnecessary copies and allocations by, for example, making `p` a pointer into internal storage and by restoring `*(p + r)` to `charT()` after evaluating `OP`.

```
constexpr size_type capacity() const noexcept;
```

Returns: The size of the allocated storage in the string.

Complexity: Constant time.

```
constexpr void reserve(size_type res_arg);
```

Effects: A directive that informs a `basic_string` of a planned change in size, so that the storage allocation can be managed accordingly. After `reserve()`, `capacity()` is greater or equal to the argument of `reserve` if reallocation happens; and equal to the previous value of `capacity()` otherwise. Reallocation happens at this point if and only if the current capacity is less than the argument of `reserve()`.

Throws: `length_error` if `res_arg > max_size()` or any exceptions thrown by `allocator_traits<Allocator>::allocate`.

```
constexpr void shrink_to_fit();
```

Effects: `shrink_to_fit` is a non-binding request to reduce `capacity()` to `size()`.

NOTE 1 The request is non-binding to allow latitude for implementation-specific optimizations.

It does not increase `capacity()`, but may reduce `capacity()` by causing reallocation.

Complexity: If the size is not equal to the old capacity, linear in the size of the sequence; otherwise constant.

Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator.

NOTE 2 If no reallocation happens, they remain valid.

```
constexpr void clear() noexcept;
```

Effects: Equivalent to: `erase(begin(), end());`

```
[[nodiscard]] constexpr bool empty() const noexcept;
```

Effects: Equivalent to: `return size() == 0;`

23.4.3.6 Element access

[string.access]

```
constexpr const_reference operator[](size_type pos) const;
constexpr reference      operator[](size_type pos);
```

Preconditions: `pos <= size()`.

Returns: `*(begin() + pos)` if `pos < size()`. Otherwise, returns a reference to an object of type `charT` with value `charT()`, where modifying the object to any value other than `charT()` leads to undefined behavior.

Throws: Nothing.

Complexity: Constant time.

```
constexpr const_reference at(size_type pos) const;
constexpr reference      at(size_type pos);
```

Returns: `operator[](pos)`.

Throws: `out_of_range` if `pos >= size()`.

```
constexpr const charT& front() const;
constexpr charT& front();
```

Preconditions: `!empty()`.

Effects: Equivalent to: `return operator[](0);`

```
constexpr const charT& back() const;
constexpr charT& back();
```

Preconditions: `!empty()`.

Effects: Equivalent to: `return operator[](size() - 1);`

23.4.3.7 Modifiers

[string.modifiers]

23.4.3.7.1 basic_string::operator+=

[string.op.append]

```
constexpr basic_string& operator+=(const basic_string& str);
```

Effects: Equivalent to: `return append(str);`

```
template<class T>
```

```
constexpr basic_string& operator+=(const T& t);
```

Constraints:

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Effects: Equivalent to:

```
basic_string_view<charT, traits> sv = t;
return append(sv);
```

```
constexpr basic_string& operator+=(const charT* s);
```

Effects: Equivalent to: `return append(s);`

```
constexpr basic_string& operator+=(charT c);
```

Effects: Equivalent to: `return append(size_type{1}, c);`

```
constexpr basic_string& operator+=(initializer_list<charT> il);
```

Effects: Equivalent to: `return append(il);`

23.4.3.7.2 basic_string::append

[string.append]

```
constexpr basic_string& append(const basic_string& str);
```

Effects: Equivalent to: `return append(str.data(), str.size());`

```
constexpr basic_string& append(const basic_string& str, size_type pos, size_type n = npos);
```

Effects: Equivalent to:

```
return append(basic_string_view<charT, traits>(str).substr(pos, n));
```

```
template<class T>
```

```
constexpr basic_string& append(const T& t);
```

Constraints:

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Effects: Equivalent to:

```
basic_string_view<charT, traits> sv = t;
return append(sv.data(), sv.size());
```

```
template<class T>
```

```
constexpr basic_string& append(const T& t, size_type pos, size_type n = npos);
```

Constraints:

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Effects: Equivalent to:

```
basic_string_view<charT, traits> sv = t;
return append(sv.substr(pos, n));
```

```
constexpr basic_string& append(const charT* s, size_type n);
```

Preconditions: `[s, s + n)` is a valid range.

Effects: Appends a copy of the range `[s, s + n)` to the string.

Returns: *this.

```
constexpr basic_string& append(const charT* s);
```

Effects: Equivalent to: `return append(s, traits::length(s));`

```
constexpr basic_string& append(size_type n, charT c);
```

Effects: Appends `n` copies of `c` to the string.

Returns: *this.

```
template<class InputIterator>
```

```
constexpr basic_string& append(InputIterator first, InputIterator last);
```

Constraints: InputIterator is a type that qualifies as an input iterator (24.2.2.2).

Effects: Equivalent to: `return append(basic_string(first, last, get_allocator()));`

```
template<container-compatible-range<charT> R>
```

```
constexpr basic_string& append_range(R&& rg);
```

Effects: Equivalent to: `return append(basic_string(from_range, std::forward<R>(rg), get_allocator()));`

```
constexpr basic_string& append(initializer_list<charT> il);
```

Effects: Equivalent to: `return append(il.begin(), il.size());`

```
constexpr void push_back(charT c);
```

Effects: Equivalent to `append(size_type{1}, c)`.

23.4.3.7.3 basic_string::assign

[string.assign]

```
constexpr basic_string& assign(const basic_string& str);
```

Effects: Equivalent to: `return *this = str;`

```
constexpr basic_string& assign(basic_string&& str)
```

```
noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
allocator_traits<Allocator>::is_always_equal::value);
```

Effects: Equivalent to: `return *this = std::move(str);`

```
constexpr basic_string& assign(const basic_string& str, size_type pos, size_type n = npos);
```

Effects: Equivalent to:

```
return assign(basic_string_view<charT, traits>(str).substr(pos, n));
```

```
template<class T>
```

```
constexpr basic_string& assign(const T& t);
```

Constraints:

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Effects: Equivalent to:

```
basic_string_view<charT, traits> sv = t;
return assign(sv.data(), sv.size());
```

```
template<class T>
```

```
constexpr basic_string& assign(const T& t, size_type pos, size_type n = npos);
```

Constraints:

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Effects: Equivalent to:

```
basic_string_view<charT, traits> sv = t;
return assign(sv.substr(pos, n));
```

```
constexpr basic_string& assign(const charT* s, size_type n);
```

Preconditions: $[s, s + n)$ is a valid range.

Effects: Replaces the string controlled by **this* with a copy of the range $[s, s + n)$.

Returns: **this*.

```
constexpr basic_string& assign(const charT* s);
```

Effects: Equivalent to: `return assign(s, traits::length(s));`

```
constexpr basic_string& assign(initializer_list<charT> il);
```

Effects: Equivalent to: `return assign(il.begin(), il.size());`

```
constexpr basic_string& assign(size_type n, charT c);
```

Effects: Equivalent to:

```
clear();
resize(n, c);
return *this;
```

```
template<class InputIterator>
```

```
constexpr basic_string& assign(InputIterator first, InputIterator last);
```

Constraints: `InputIterator` is a type that qualifies as an input iterator (24.2.2.2).

Effects: Equivalent to: `return assign(basic_string(first, last, get_allocator()));`

```
template<container-compatible-range<charT> R>
```

```
constexpr basic_string& assign_range(R&& rg);
```

Effects: Equivalent to: `return assign(basic_string(from_range, std::forward<R>(rg), get_allocator()));`

23.4.3.7.4 `basic_string::insert`

[string.insert]

```
constexpr basic_string& insert(size_type pos, const basic_string& str);
```

Effects: Equivalent to: `return insert(pos, str.data(), str.size());`

```
constexpr basic_string& insert(size_type pos1, const basic_string& str,
                             size_type pos2, size_type n = npos);
```

Effects: Equivalent to:

```
return insert(pos1, basic_string_view<charT, traits>(str), pos2, n);
```

```
template<class T>
```

```
constexpr basic_string& insert(size_type pos, const T& t);
```

Constraints:

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Effects: Equivalent to:

```
basic_string_view<charT, traits> sv = t;
return insert(pos, sv.data(), sv.size());
```

```
template<class T>
```

```
constexpr basic_string& insert(size_type pos1, const T& t,
                             size_type pos2, size_type n = npos);
```

Constraints:

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Effects: Equivalent to:

```
basic_string_view<charT, traits> sv = t;
return insert(pos1, sv.substr(pos2, n));
```

```
constexpr basic_string& insert(size_type pos, const charT* s, size_type n);
```

Preconditions: `[s, s + n)` is a valid range.

Effects: Inserts a copy of the range `[s, s + n)` immediately before the character at position `pos` if `pos < size()`, or otherwise at the end of the string.

Returns: `*this`.

Throws:

- `out_of_range` if `pos > size()`,
- `length_error` if `n > max_size() - size()`, or
- any exceptions thrown by `allocator_traits<Allocator>::allocate`.

```
constexpr basic_string& insert(size_type pos, const charT* s);
```

Effects: Equivalent to: `return insert(pos, s, traits::length(s));`

```
constexpr basic_string& insert(size_type pos, size_type n, charT c);
```

Effects: Inserts `n` copies of `c` before the character at position `pos` if `pos < size()`, or otherwise at the end of the string.

Returns: `*this`

Throws:

- `out_of_range` if `pos > size()`,
- `length_error` if `n > max_size() - size()`, or
- any exceptions thrown by `allocator_traits<Allocator>::allocate`.

```
constexpr iterator insert(const_iterator p, charT c);
```

Preconditions: `p` is a valid iterator on `*this`.

Effects: Inserts a copy of `c` at the position `p`.

Returns: An iterator which refers to the inserted character.

```
constexpr iterator insert(const_iterator p, size_type n, charT c);
```

Preconditions: `p` is a valid iterator on `*this`.

Effects: Inserts `n` copies of `c` at the position `p`.

Returns: An iterator which refers to the first inserted character, or `p` if `n == 0`.

```
template<class InputIterator>
```

```
constexpr iterator insert(const_iterator p, InputIterator first, InputIterator last);
```

Constraints: `InputIterator` is a type that qualifies as an input iterator (24.2.2.2).

Preconditions: `p` is a valid iterator on `*this`.

Effects: Equivalent to `insert(p - begin(), basic_string(first, last, get_allocator()))`.

Returns: An iterator which refers to the first inserted character, or `p` if `first == last`.

```
template<container-compatible-range<charT> R>
```

```
constexpr iterator insert_range(const_iterator p, R&& rg);
```

Preconditions: `p` is a valid iterator on `*this`.

Effects: Equivalent to `insert(p - begin(), basic_string(from_range, std::forward<R>(rg), get_allocator()))`.

Returns: An iterator which refers to the first inserted character, or `p` if `rg` is empty.

```
constexpr iterator insert(const_iterator p, initializer_list<charT> il);
```

Effects: Equivalent to: `return insert(p, il.begin(), il.end());`

23.4.3.7.5 basic_string::erase**[string.erase]**

```
constexpr basic_string& erase(size_type pos = 0, size_type n = npos);
```

Effects: Determines the effective length `xlen` of the string to be removed as the smaller of `n` and `size() - pos`. Removes the characters in the range `[begin() + pos, begin() + pos + xlen)`.

Returns: `*this`.

Throws: `out_of_range` if `pos > size()`.

```
constexpr iterator erase(const_iterator p);
```

Preconditions: `p` is a valid dereferenceable iterator on `*this`.

Effects: Removes the character referred to by `p`.

Returns: An iterator which points to the element immediately following `p` prior to the element being erased. If no such element exists, `end()` is returned.

Throws: Nothing.

```
constexpr iterator erase(const_iterator first, const_iterator last);
```

Preconditions: `first` and `last` are valid iterators on `*this`. `[first, last)` is a valid range.

Effects: Removes the characters in the range `[first, last)`.

Returns: An iterator which points to the element pointed to by `last` prior to the other elements being erased. If no such element exists, `end()` is returned.

Throws: Nothing.

```
constexpr void pop_back();
```

Preconditions: `!empty()`.

Effects: Equivalent to `erase(end() - 1)`.

Throws: Nothing.

23.4.3.7.6 basic_string::replace**[string.replace]**

```
constexpr basic_string& replace(size_type pos1, size_type n1, const basic_string& str);
```

Effects: Equivalent to: `return replace(pos1, n1, str.data(), str.size());`

```
constexpr basic_string& replace(size_type pos1, size_type n1, const basic_string& str,
                               size_type pos2, size_type n2 = npos);
```

Effects: Equivalent to:

```
return replace(pos1, n1, basic_string_view<charT, traits>(str).substr(pos2, n2));
```

```
template<class T>
```

```
constexpr basic_string& replace(size_type pos1, size_type n1, const T& t);
```

Constraints:

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Effects: Equivalent to:

```
basic_string_view<charT, traits> sv = t;
return replace(pos1, n1, sv.data(), sv.size());
```

```
template<class T>
```

```
constexpr basic_string& replace(size_type pos1, size_type n1, const T& t,
                               size_type pos2, size_type n2 = npos);
```

Constraints:

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Effects: Equivalent to:

```
basic_string_view<charT, traits> sv = t;
return replace(pos1, n1, sv.substr(pos2, n2));
```

```
constexpr basic_string& replace(size_type pos1, size_type n1, const charT* s, size_type n2);
```

Preconditions: $[s, s + n2)$ is a valid range.

Effects: Determines the effective length $xlen$ of the string to be removed as the smaller of $n1$ and $size() - pos1$. If $size() - xlen \geq max\_size() - n2$ throws `length_error`. Otherwise, the function replaces the characters in the range $[begin() + pos1, begin() + pos1 + xlen)$ with a copy of the range $[s, s + n2)$.

Returns: `*this`.

Throws:

- `out_of_range` if $pos1 > size()$,
- `length_error` if the length of the resulting string would exceed $max\_size()$, or
- any exceptions thrown by `allocator_traits<Allocator>::allocate`.

```
constexpr basic_string& replace(size_type pos, size_type n, const charT* s);
```

Effects: Equivalent to: `return replace(pos, n, s, traits::length(s));`

```
constexpr basic_string& replace(size_type pos1, size_type n1, size_type n2, charT c);
```

Effects: Determines the effective length $xlen$ of the string to be removed as the smaller of $n1$ and $size() - pos1$. If $size() - xlen \geq max\_size() - n2$ throws `length_error`. Otherwise, the function replaces the characters in the range $[begin() + pos1, begin() + pos1 + xlen)$ with $n2$ copies of c .

Returns: `*this`.

Throws:

- `out_of_range` if $pos1 > size()$,
- `length_error` if the length of the resulting string would exceed $max\_size()$, or
- any exceptions thrown by `allocator_traits<Allocator>::allocate`.

```
constexpr basic_string& replace(const_iterator i1, const_iterator i2, const basic_string& str);
```

Effects: Equivalent to: `return replace(i1, i2, basic_string_view<charT, traits>(str));`

```
template<class T>
```

```
constexpr basic_string& replace(const_iterator i1, const_iterator i2, const T& t);
```

Constraints:

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Preconditions: $[begin(), i1)$ and $[i1, i2)$ are valid ranges.

Effects: Equivalent to:

```
basic_string_view<charT, traits> sv = t;
return replace(i1 - begin(), i2 - i1, sv.data(), sv.size());
```

```
constexpr basic_string& replace(const_iterator i1, const_iterator i2, const charT* s, size_type n);
```

Effects: Equivalent to: `return replace(i1, i2, basic_string_view<charT, traits>(s, n));`

```
constexpr basic_string& replace(const_iterator i1, const_iterator i2, const charT* s);
```

Effects: Equivalent to: `return replace(i1, i2, basic_string_view<charT, traits>(s));`

```
constexpr basic_string& replace(const_iterator i1, const_iterator i2, size_type n, charT c);
```

Preconditions: $[begin(), i1)$ and $[i1, i2)$ are valid ranges.

Effects: Equivalent to: `return replace(i1 - begin(), i2 - i1, n, c);`

```
template<class InputIterator>
constexpr basic_string& replace(const_iterator i1, const_iterator i2,
                               InputIterator j1, InputIterator j2);
```

Constraints: InputIterator is a type that qualifies as an input iterator (24.2.2.2).

Effects: Equivalent to: `return replace(i1, i2, basic_string(j1, j2, get_allocator()));`

```
template<container-compatible-range<charT> R>
constexpr basic_string& replace_with_range(const_iterator i1, const_iterator i2, R&& rg);
```

Effects: Equivalent to:

```
return replace(i1, i2, basic_string(from_range, std::forward<R>(rg), get_allocator()));
```

```
constexpr basic_string& replace(const_iterator i1, const_iterator i2, initializer_list<charT> il);
```

Effects: Equivalent to: `return replace(i1, i2, il.begin(), il.size());`

23.4.3.7.7 basic_string::copy [string.copy]

```
constexpr size_type copy(charT* s, size_type n, size_type pos = 0) const;
```

Effects: Equivalent to: `return basic_string_view<charT, traits>(*this).copy(s, n, pos);`

NOTE This does not terminate `s` with a null object.

23.4.3.7.8 basic_string::swap [string.swap]

```
constexpr void swap(basic_string& s)
noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
         allocator_traits<Allocator>::is_always_equal::value);
```

Preconditions: `allocator_traits<Allocator>::propagate_on_container_swap::value` is true or `get_allocator() == s.get_allocator()`.

Postconditions: `*this` contains the same sequence of characters that was in `s`, `s` contains the same sequence of characters that was in `*this`.

Throws: Nothing.

Complexity: Constant time.

23.4.3.8 String operations [string.ops]

23.4.3.8.1 Accessors [string.accessors]

```
constexpr const charT* c_str() const noexcept;
constexpr const charT* data() const noexcept;
```

Returns: A pointer `p` such that `p + i == addressof(operator[](i))` for each `i` in `[0, size())`.

Complexity: Constant time.

Remarks: The program shall not modify any of the values stored in the character array; otherwise, the behavior is undefined.

```
constexpr charT* data() noexcept;
```

Returns: A pointer `p` such that `p + i == addressof(operator[](i))` for each `i` in `[0, size())`.

Complexity: Constant time.

Remarks: The program shall not modify the value stored at `p + size()` to any value other than `charT()`; otherwise, the behavior is undefined.

```
constexpr operator basic_string_view<charT, traits>() const noexcept;
```

Effects: Equivalent to: `return basic_string_view<charT, traits>(data(), size());`

```
constexpr allocator_type get_allocator() const noexcept;
```

Returns: A copy of the Allocator object used to construct the string or, if that allocator has been replaced, a copy of the most recent replacement.

23.4.3.8.2 Searching**[string.find]**

Let F be one of `find`, `rfind`, `find_first_of`, `find_last_of`, `find_first_not_of`, and `find_last_not_of`.

- Each member function of the form

```
constexpr size_type F(const basic_string& str, size_type pos) const noexcept;
```

has effects equivalent to: `return F(basic_string_view<charT, traits>(str), pos);`

- Each member function of the form

```
constexpr size_type F(const charT* s, size_type pos) const;
```

has effects equivalent to: `return F(basic_string_view<charT, traits>(s), pos);`

- Each member function of the form

```
constexpr size_type F(const charT* s, size_type pos, size_type n) const;
```

has effects equivalent to: `return F(basic_string_view<charT, traits>(s, n), pos);`

- Each member function of the form

```
constexpr size_type F(charT c, size_type pos) const noexcept;
```

has effects equivalent to:

```
return F(basic_string_view<charT, traits>(addressof(c), 1), pos);
```

```
template<class T>
```

```
constexpr size_type find(const T& t, size_type pos = 0) const noexcept(see below);
```

```
template<class T>
```

```
constexpr size_type rfind(const T& t, size_type pos = npos) const noexcept(see below);
```

```
template<class T>
```

```
constexpr size_type find_first_of(const T& t, size_type pos = 0) const noexcept(see below);
```

```
template<class T>
```

```
constexpr size_type find_last_of(const T& t, size_type pos = npos) const noexcept(see below);
```

```
template<class T>
```

```
constexpr size_type find_first_not_of(const T& t, size_type pos = 0) const noexcept(see below);
```

```
template<class T>
```

```
constexpr size_type find_last_not_of(const T& t, size_type pos = npos) const noexcept(see below);
```

Constraints:

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Effects: Let G be the name of the function. Equivalent to:

```
basic_string_view<charT, traits> s = *this, sv = t;
return s.G(sv, pos);
```

Remarks: The exception specification is equivalent to `is_nothrow_convertible_v<const T&, basic_string_view<charT, traits>>`.

23.4.3.8.3 basic_string::substr**[string.substr]**

```
constexpr basic_string substr(size_type pos = 0, size_type n = npos) const &;
```

Effects: Equivalent to: `return basic_string(*this, pos, n);`

```
constexpr basic_string substr(size_type pos = 0, size_type n = npos) &&;
```

Effects: Equivalent to: `return basic_string(std::move(*this), pos, n);`

23.4.3.8.4 basic_string::compare**[string.compare]**

```
template<class T>
```

```
constexpr int compare(const T& t) const noexcept(see below);
```

Constraints:

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Effects: Equivalent to: `return basic_string_view<charT, traits>(*this).compare(t);`

Remarks: The exception specification is equivalent to `is_nothrow_convertible_v<const T&, basic_string_view<charT, traits>>`.

```
template<class T>
constexpr int compare(size_type pos1, size_type n1, const T& t) const;
```

Constraints:

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Effects: Equivalent to:

```
return basic_string_view<charT, traits>(*this).substr(pos1, n1).compare(t);
```

```
template<class T>
constexpr int compare(size_type pos1, size_type n1, const T& t,
                    size_type pos2, size_type n2 = npos) const;
```

Constraints:

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

Effects: Equivalent to:

```
basic_string_view<charT, traits> s = *this, sv = t;
return s.substr(pos1, n1).compare(sv.substr(pos2, n2));
```

```
constexpr int compare(const basic_string& str) const noexcept;
```

Effects: Equivalent to: `return compare(basic_string_view<charT, traits>(str));`

```
constexpr int compare(size_type pos1, size_type n1, const basic_string& str) const;
```

Effects: Equivalent to: `return compare(pos1, n1, basic_string_view<charT, traits>(str));`

```
constexpr int compare(size_type pos1, size_type n1, const basic_string& str,
                    size_type pos2, size_type n2 = npos) const;
```

Effects: Equivalent to:

```
return compare(pos1, n1, basic_string_view<charT, traits>(str), pos2, n2);
```

```
constexpr int compare(const charT* s) const;
```

Effects: Equivalent to: `return compare(basic_string_view<charT, traits>(s));`

```
constexpr int compare(size_type pos, size_type n1, const charT* s) const;
```

Effects: Equivalent to: `return compare(pos, n1, basic_string_view<charT, traits>(s));`

```
constexpr int compare(size_type pos, size_type n1, const charT* s, size_type n2) const;
```

Effects: Equivalent to: `return compare(pos, n1, basic_string_view<charT, traits>(s, n2));`

23.4.3.8.5 `basic_string::starts_with` [string.starts.with]

```
constexpr bool starts_with(basic_string_view<charT, traits> x) const noexcept;
constexpr bool starts_with(charT x) const noexcept;
constexpr bool starts_with(const charT* x) const;
```

Effects: Equivalent to:

```
return basic_string_view<charT, traits>(data(), size()).starts_with(x);
```

23.4.3.8.6 `basic_string::ends_with` [string.ends.with]

```
constexpr bool ends_with(basic_string_view<charT, traits> x) const noexcept;
constexpr bool ends_with(charT x) const noexcept;
constexpr bool ends_with(const charT* x) const;
```

Effects: Equivalent to:

```
return basic_string_view<charT, traits>(data(), size()).ends_with(x);
```

23.4.3.8.7 basic_string::contains

[string.contains]

```
constexpr bool contains(basic_string_view<charT, traits> x) const noexcept;
constexpr bool contains(charT x) const noexcept;
constexpr bool contains(const charT* x) const;
```

Effects: Equivalent to:

```
return basic_string_view<charT, traits>(data(), size()).contains(x);
```

23.4.4 Non-member functions

[string.nonmembers]

23.4.4.1 operator+

[string.op.plus]

```
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>& lhs,
          const basic_string<charT, traits, Allocator>& rhs);
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);
```

Effects: Equivalent to:

```
basic_string<charT, traits, Allocator> r = lhs;
r.append(rhs);
return r;
```

```
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs,
          const basic_string<charT, traits, Allocator>& rhs);
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs, const charT* rhs);
```

Effects: Equivalent to:

```
lhs.append(rhs);
return std::move(lhs);
```

```
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs,
          basic_string<charT, traits, Allocator>&& rhs);
```

Effects: Equivalent to:

```
lhs.append(rhs);
return std::move(lhs);
```

except that both `lhs` and `rhs` are left in valid but unspecified states.

NOTE If `lhs` and `rhs` have equal allocators, the implementation can move from either.

```
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>& lhs,
          basic_string<charT, traits, Allocator>&& rhs);
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const charT* lhs, basic_string<charT, traits, Allocator>&& rhs);
```

Effects: Equivalent to:

```
rhs.insert(0, lhs);
return std::move(rhs);
```

```
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);
```

Effects: Equivalent to:

```
basic_string<charT, traits, Allocator> r = rhs;
r.insert(0, lhs);
return r;
```

```
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(charT lhs, const basic_string<charT, traits, Allocator>& rhs);
```

Effects: Equivalent to:

```
basic_string<charT, traits, Allocator> r = rhs;
r.insert(r.begin(), lhs);
return r;
```

```
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(charT lhs, basic_string<charT, traits, Allocator>&& rhs);
```

Effects: Equivalent to:

```
rhs.insert(rhs.begin(), lhs);
return std::move(rhs);
```

```
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>& lhs, charT rhs);
```

Effects: Equivalent to:

```
basic_string<charT, traits, Allocator> r = lhs;
r.push_back(rhs);
return r;
```

```
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs, charT rhs);
```

Effects: Equivalent to:

```
lhs.push_back(rhs);
return std::move(lhs);
```

23.4.4.2 Non-member comparison operator functions

[string.cmp]

```
template<class charT, class traits, class Allocator>
constexpr bool
operator==(const basic_string<charT, traits, Allocator>& lhs,
           const basic_string<charT, traits, Allocator>& rhs) noexcept;
template<class charT, class traits, class Allocator>
constexpr bool operator==(const basic_string<charT, traits, Allocator>& lhs,
                           const charT* rhs);
```

```
template<class charT, class traits, class Allocator>
constexpr see below operator<=>(const basic_string<charT, traits, Allocator>& lhs,
                                const basic_string<charT, traits, Allocator>& rhs) noexcept;
template<class charT, class traits, class Allocator>
constexpr see below operator<=>(const basic_string<charT, traits, Allocator>& lhs,
                                const charT* rhs);
```

Effects: Let *op* be the operator. Equivalent to:

```
return basic_string_view<charT, traits>(lhs) op basic_string_view<charT, traits>(rhs);
```

23.4.4.3 swap

[string.special]

```
template<class charT, class traits, class Allocator>
constexpr void
swap(basic_string<charT, traits, Allocator>& lhs,
     basic_string<charT, traits, Allocator>& rhs)
    noexcept(noexcept(lhs.swap(rhs)));
```

Effects: Equivalent to `lhs.swap(rhs)`.

23.4.4.4 Inserters and extractors

[string.io]

```
template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, basic_string<charT, traits, Allocator>& str);
```

Effects: Behaves as a formatted input function (31.7.5.3.1). After constructing a `sentry` object, if the `sentry` object returns `true` when converted to a value of type `bool`, calls `str.erase()` and then extracts characters from `is` and appends them to `str` as if by calling `str.append(1, c)`. If `is.width()` is greater than zero, the maximum number `n` of characters appended is `is.width()`; otherwise `n` is `str.max_size()`. Characters are extracted and appended until any of the following occurs:

- `n` characters are stored;
- end-of-file occurs on the input sequence;
- `isspace(c, is.getloc())` is `true` for the next available input character `c`.

After the last character (if any) is extracted, `is.width(0)` is called and the `sentry` object is destroyed.

If the function extracts no characters, `ios_base::failbit` is set in the input function's local error state before `setstate` is called.

Returns: `is`.

```
template<class charT, class traits, class Allocator>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os,
          const basic_string<charT, traits, Allocator>& str);

Effects: Equivalent to: return os << basic_string_view<charT, traits>(str);
```

```
template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
getline(basic_istream<charT, traits>& is,
        basic_string<charT, traits, Allocator>& str,
        charT delim);

template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
getline(basic_istream<charT, traits>&& is,
        basic_string<charT, traits, Allocator>& str,
        charT delim);
```

Effects: Behaves as an unformatted input function (31.7.5.4), except that it does not affect the value returned by subsequent calls to `basic_istream<>::gcount()`. After constructing a `sentry` object, if the `sentry` object returns `true` when converted to a value of type `bool`, calls `str.erase()` and then extracts characters from `is` and appends them to `str` as if by calling `str.append(1, c)` until any of the following occurs:

- end-of-file occurs on the input sequence;
- `traits::eq(c, delim)` for the next available input character `c` (in which case, `c` is extracted but not appended);
- `str.max_size()` characters are stored (in which case, `ios_base::failbit` is set in the input function's local error state).

The conditions are tested in the order shown. In any case, after the last character is extracted, the `sentry` object is destroyed.

If the function extracts no characters, `ios_base::failbit` is set in the input function's local error state before `setstate` is called.

Returns: is.

```
template<class charT, class traits, class Allocator>
    basic_istream<charT, traits>&
        getline(basic_istream<charT, traits>& is,
                basic_string<charT, traits, Allocator>& str);
template<class charT, class traits, class Allocator>
    basic_istream<charT, traits>&
        getline(basic_istream<charT, traits>&& is,
                basic_string<charT, traits, Allocator>& str);
```

Returns: getline(is, str, is.widen('\n')).

23.4.4.5 Erasure

[string.erase]

```
template<class charT, class traits, class Allocator, class U>
    constexpr typename basic_string<charT, traits, Allocator>::size_type
        erase(basic_string<charT, traits, Allocator>& c, const U& value);
```

Effects: Equivalent to:

```
auto it = remove(c.begin(), c.end(), value);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;
```

```
template<class charT, class traits, class Allocator, class Predicate>
    constexpr typename basic_string<charT, traits, Allocator>::size_type
        erase_if(basic_string<charT, traits, Allocator>& c, Predicate pred);
```

Effects: Equivalent to:

```
auto it = remove_if(c.begin(), c.end(), pred);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;
```

23.4.5 Numeric conversions

[string.conversions]

```
int stoi(const string& str, size_t* idx = nullptr, int base = 10);
long stol(const string& str, size_t* idx = nullptr, int base = 10);
unsigned long stoul(const string& str, size_t* idx = nullptr, int base = 10);
long long stoll(const string& str, size_t* idx = nullptr, int base = 10);
unsigned long long stoull(const string& str, size_t* idx = nullptr, int base = 10);
```

Effects: The first two functions call `strtol(str.c_str(), ptr, base)`, and the last three functions call `strtoul(str.c_str(), ptr, base)`, `strtoll(str.c_str(), ptr, base)`, and `strtoull(str.c_str(), ptr, base)` respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx != nullptr`, the function stores in `*idx` the index of the first unconverted element of `str`.

Returns: The converted result.

Throws: `invalid_argument` if `strtol`, `strtoul`, `strtoll`, or `strtoull` reports that no conversion can be performed. Throws `out_of_range` if `strtol`, `strtoul`, `strtoll` or `strtoull` sets `errno` to `ERANGE`, or if the converted value is outside the range of representable values for the return type.

```
float stof(const string& str, size_t* idx = nullptr);
double stod(const string& str, size_t* idx = nullptr);
long double stold(const string& str, size_t* idx = nullptr);
```

Effects: These functions call `strtof(str.c_str(), ptr)`, `strtod(str.c_str(), ptr)`, and `strtold(str.c_str(), ptr)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx != nullptr`, the function stores in `*idx` the index of the first unconverted element of `str`.

Returns: The converted result.

Throws: `invalid_argument` if `strtof`, `strtod`, or `strtold` reports that no conversion can be performed.
Throws `out_of_range` if `strtof`, `strtod`, or `strtold` sets `errno` to `ERANGE` or if the converted value is outside the range of representable values for the return type.

```
string to_string(int val);
string to_string(unsigned val);
string to_string(long val);
string to_string(unsigned long val);
string to_string(long long val);
string to_string(unsigned long long val);
string to_string(float val);
string to_string(double val);
string to_string(long double val);
```

Returns: Each function returns a `string` object holding the character representation of the value of its argument that would be generated by calling `sprintf(buf, fmt, val)` with a format specifier of `"%d"`, `"%u"`, `"%ld"`, `"%lu"`, `"%lld"`, `"%llu"`, `"%f"`, `"%f"`, or `"%Lf"`, respectively, where `buf` designates an internal character buffer of sufficient size.

```
int stoi(const wstring& str, size_t* idx = nullptr, int base = 10);
long stol(const wstring& str, size_t* idx = nullptr, int base = 10);
unsigned long stoul(const wstring& str, size_t* idx = nullptr, int base = 10);
long long stoll(const wstring& str, size_t* idx = nullptr, int base = 10);
unsigned long long stoull(const wstring& str, size_t* idx = nullptr, int base = 10);
```

Effects: The first two functions call `wcstol(str.c_str(), ptr, base)`, and the last three functions call `wcstoul(str.c_str(), ptr, base)`, `wcstoll(str.c_str(), ptr, base)`, and `wcstoull(str.c_str(), ptr, base)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx != nullptr`, the function stores in `*idx` the index of the first unconverted element of `str`.

Returns: The converted result.

Throws: `invalid_argument` if `wcstol`, `wcstoul`, `wcstoll`, or `wcstoull` reports that no conversion can be performed. *Throws* `out_of_range` if the converted value is outside the range of representable values for the return type.

```
float stof(const wstring& str, size_t* idx = nullptr);
double stod(const wstring& str, size_t* idx = nullptr);
long double stold(const wstring& str, size_t* idx = nullptr);
```

Effects: These functions call `wcstof(str.c_str(), ptr)`, `wcstod(str.c_str(), ptr)`, and `wcstold(str.c_str(), ptr)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx != nullptr`, the function stores in `*idx` the index of the first unconverted element of `str`.

Returns: The converted result.

Throws: `invalid_argument` if `wcstof`, `wcstod`, or `wcstold` reports that no conversion can be performed. *Throws* `out_of_range` if `wcstof`, `wcstod`, or `wcstold` sets `errno` to `ERANGE`.

```
wstring to_wstring(int val);
wstring to_wstring(unsigned val);
wstring to_wstring(long val);
wstring to_wstring(unsigned long val);
wstring to_wstring(long long val);
wstring to_wstring(unsigned long long val);
wstring to_wstring(float val);
wstring to_wstring(double val);
wstring to_wstring(long double val);
```

Returns: Each function returns a `wstring` object holding the character representation of the value of its argument that would be generated by calling `swprintf(buf, buffsz, fmt, val)` with a format specifier of `L"%d"`, `L"%u"`, `L"%ld"`, `L"%lu"`, `L"%lld"`, `L"%llu"`, `L"%f"`, `L"%f"`, or `L"%Lf"`, respectively, where `buf` designates an internal character buffer of sufficient size `buffersz`.

23.4.6 Hash support

[basic.string.hash]

```
template<class A> struct hash<basic_string<char, char_traits<char>, A>>;
template<class A> struct hash<basic_string<char8_t, char_traits<char8_t>, A>>;
template<class A> struct hash<basic_string<char16_t, char_traits<char16_t>, A>>;
template<class A> struct hash<basic_string<char32_t, char_traits<char32_t>, A>>;
template<class A> struct hash<basic_string<wchar_t, char_traits<wchar_t>, A>>;
```

If *S* is one of these string types, *SV* is the corresponding string view type, and *s* is an object of type *S*, then `hash<S>()(s) == hash<SV>()(SV(s))`.

23.4.7 Suffix for basic_string literals

[basic.string.literals]

```
constexpr string operator""s(const char* str, size_t len);
```

Returns: `string{str, len}`.

```
constexpr u8string operator""s(const char8_t* str, size_t len);
```

Returns: `u8string{str, len}`.

```
constexpr u16string operator""s(const char16_t* str, size_t len);
```

Returns: `u16string{str, len}`.

```
constexpr u32string operator""s(const char32_t* str, size_t len);
```

Returns: `u32string{str, len}`.

```
constexpr wstring operator""s(const wchar_t* str, size_t len);
```

Returns: `wstring{str, len}`.

NOTE The same suffix *s* is used for `chrono::duration` literals denoting seconds but there is no conflict, since duration suffixes apply to numbers and string literal suffixes apply to character array literals.

23.5 Null-terminated sequence utilities

[c.strings]

23.5.1 Header <cctype> synopsis

[cctype.syn]

```
namespace std {
    int isalnum(int c);
    int isalpha(int c);
    int isblank(int c);
    int iscntrl(int c);
    int isdigit(int c);
    int isgraph(int c);
    int islower(int c);
    int isprint(int c);
    int ispunct(int c);
    int isspace(int c);
    int isupper(int c);
    int isxdigit(int c);
    int tolower(int c);
    int toupper(int c);
}
```

The contents and meaning of the header <cctype> are the same as the C standard library header <ctype.h>. See also ISO/IEC 9899:2018, 7.4.

23.5.2 Header <cwctype> synopsis

[cwctype.syn]

```
namespace std {
    using wint_t = see below;
    using wctrans_t = see below;
    using wctype_t = see below;

    int iswalnum(wint_t wc);
    int iswalpha(wint_t wc);
    int iswblank(wint_t wc);
    int iswcntrl(wint_t wc);
```

```

int iswdigit(wint_t wc);
int iswgraph(wint_t wc);
int iswlower(wint_t wc);
int iswprint(wint_t wc);
int iswpunct(wint_t wc);
int iswspace(wint_t wc);
int iswupper(wint_t wc);
int iswxdigit(wint_t wc);
int iswctype(wint_t wc, wctype_t desc);
wctype_t wctype(const char* property);
wint_t towlower(wint_t wc);
wint_t towupper(wint_t wc);
wint_t towctrans(wint_t wc, wctrans_t desc);
wctrans_t wctrans(const char* property);
}

```

#define WEOF *see below*

The contents and meaning of the header `<cwctype>` are the same as the C standard library header `<wctype.h>`. See also ISO/IEC 9899:2018, 7.30.

23.5.3 Header `<cstring>` synopsis

[cstring.syn]

```

namespace std {
    using size_t = see 17.2.4;

    void* memcpy(void* s1, const void* s2, size_t n);
    void* memmove(void* s1, const void* s2, size_t n);
    char* strcpy(char* s1, const char* s2);
    char* strncpy(char* s1, const char* s2, size_t n);
    char* strcat(char* s1, const char* s2);
    char* strncat(char* s1, const char* s2, size_t n);
    int memcmp(const void* s1, const void* s2, size_t n);
    int strcmp(const char* s1, const char* s2);
    int strcoll(const char* s1, const char* s2);
    int strncmp(const char* s1, const char* s2, size_t n);
    size_t strxfrm(char* s1, const char* s2, size_t n);
    const void* memchr(const void* s, int c, size_t n);           // see 16.2
    void* memchr(void* s, int c, size_t n);                       // see 16.2
    const char* strchr(const char* s, int c);                     // see 16.2
    char* strchr(char* s, int c);                                 // see 16.2
    size_t strcspn(const char* s1, const char* s2);
    const char* strpbrk(const char* s1, const char* s2);         // see 16.2
    char* strpbrk(char* s1, const char* s2);                     // see 16.2
    const char* strrchr(const char* s, int c);                   // see 16.2
    char* strrchr(char* s, int c);                               // see 16.2
    size_t strspn(const char* s1, const char* s2);
    const char* strstr(const char* s1, const char* s2);          // see 16.2
    char* strstr(char* s1, const char* s2);                      // see 16.2
    char* strtok(char* s1, const char* s2);
    void* memset(void* s, int c, size_t n);
    char* strerror(int errnum);
    size_t strlen(const char* s);
}

```

#define NULL *see 17.2.3*

The contents and meaning of the header `<cstring>` are the same as the C standard library header `<string.h>`. The functions `strerror` and `strtok` are not required to avoid data races (16.4.6.10).

The functions `memcpy` and `memmove` are signal-safe (17.13.5). Both functions implicitly create objects (6.7.2) in the destination region of storage immediately prior to copying the sequence of characters to the destination.

NOTE The functions `strchr`, `strpbrk`, `strrchr`, `strstr`, and `memchr`, have different signatures in this document, but they have the same behavior as in the C standard library (16.2).

See also ISO/IEC 9899:2018, 7.24.

23.5.4 Header <wchar> synopsis

[wchar.syn]

```
namespace std {
    using size_t = see 17.2.4;
    using mbstate_t = see below;
    using wint_t = see below;

    struct tm;

    int fwprintf(FILE* stream, const wchar_t* format, ...);
    int fwsscanf(FILE* stream, const wchar_t* format, ...);
    int swprintf(wchar_t* s, size_t n, const wchar_t* format, ...);
    int swscanf(const wchar_t* s, const wchar_t* format, ...);
    int vfwprintf(FILE* stream, const wchar_t* format, va_list arg);
    int vfwscanf(FILE* stream, const wchar_t* format, va_list arg);
    int vswprintf(wchar_t* s, size_t n, const wchar_t* format, va_list arg);
    int vswscanf(const wchar_t* s, const wchar_t* format, va_list arg);
    int vwprintf(const wchar_t* format, va_list arg);
    int vwscanf(const wchar_t* format, va_list arg);
    int wprintf(const wchar_t* format, ...);
    int wscanf(const wchar_t* format, ...);
    wint_t fgetwc(FILE* stream);
    wchar_t* fgetws(wchar_t* s, int n, FILE* stream);
    wint_t fputwc(wchar_t c, FILE* stream);
    int fputws(const wchar_t* s, FILE* stream);
    int fwide(FILE* stream, int mode);
    wint_t getwc(FILE* stream);
    wint_t getwchar();
    wint_t putwc(wchar_t c, FILE* stream);
    wint_t putwchar(wchar_t c);
    wint_t ungetwc(wint_t c, FILE* stream);
    double wcstod(const wchar_t* nptr, wchar_t** endptr);
    float wcstof(const wchar_t* nptr, wchar_t** endptr);
    long double wcstold(const wchar_t* nptr, wchar_t** endptr);
    long int wcstol(const wchar_t* nptr, wchar_t** endptr, int base);
    long long int wcstoll(const wchar_t* nptr, wchar_t** endptr, int base);
    unsigned long int wcstoul(const wchar_t* nptr, wchar_t** endptr, int base);
    unsigned long long int wcstoull(const wchar_t* nptr, wchar_t** endptr, int base);
    wchar_t* wcsncpy(wchar_t* s1, const wchar_t* s2);
    wchar_t* wcsncpy(wchar_t* s1, const wchar_t* s2, size_t n);
    wchar_t* wmemcpy(wchar_t* s1, const wchar_t* s2, size_t n);
    wchar_t* wmemmove(wchar_t* s1, const wchar_t* s2, size_t n);
    wchar_t* wscat(wchar_t* s1, const wchar_t* s2);
    wchar_t* wcsncat(wchar_t* s1, const wchar_t* s2, size_t n);
    int wcsncmp(const wchar_t* s1, const wchar_t* s2);
    int wscoll(const wchar_t* s1, const wchar_t* s2);
    int wcsncmp(const wchar_t* s1, const wchar_t* s2, size_t n);
    size_t wcsxfrm(wchar_t* s1, const wchar_t* s2, size_t n);
    int wmemcmp(const wchar_t* s1, const wchar_t* s2, size_t n);
    const wchar_t* wcschr(const wchar_t* s, wchar_t c); // see 16.2
    wchar_t* wcschr(wchar_t* s, wchar_t c); // see 16.2
    size_t wcslen(const wchar_t* s1, const wchar_t* s2);
    const wchar_t* wcsrchr(const wchar_t* s1, const wchar_t* s2); // see 16.2
    wchar_t* wcsrchr(wchar_t* s1, const wchar_t* s2); // see 16.2
    const wchar_t* wcsrchr(const wchar_t* s, wchar_t c); // see 16.2
    wchar_t* wcsrchr(wchar_t* s, wchar_t c); // see 16.2
    size_t wcsspn(const wchar_t* s1, const wchar_t* s2);
    const wchar_t* wcsstr(const wchar_t* s1, const wchar_t* s2); // see 16.2
    wchar_t* wcsstr(wchar_t* s1, const wchar_t* s2); // see 16.2
    wchar_t* wcstok(wchar_t* s1, const wchar_t* s2, wchar_t** ptr);
    const wchar_t* wmemchr(const wchar_t* s, wchar_t c, size_t n); // see 16.2
    wchar_t* wmemchr(wchar_t* s, wchar_t c, size_t n); // see 16.2
```

```

size_t wcslen(const wchar_t* s);
wchar_t* wmemset(wchar_t* s, wchar_t c, size_t n);
size_t wcsftime(wchar_t* s, size_t maxsize, const wchar_t* format, const tm* timeptr);
wint_t btowc(int c);
int wctob(wint_t c);

// 23.5.6, multibyte / wide string and character conversion functions
int mbsinit(const mbstate_t* ps);
size_t mbrlen(const char* s, size_t n, mbstate_t* ps);
size_t mbrtowc(wchar_t* pwc, const char* s, size_t n, mbstate_t* ps);
size_t wctomb(char* s, wchar_t wc, mbstate_t* ps);
size_t mbsrtowcs(wchar_t* dst, const char** src, size_t len, mbstate_t* ps);
size_t wcsrtombs(char* dst, const wchar_t** src, size_t len, mbstate_t* ps);
}

#define NULL see 17.2.3
#define WCHAR_MAX see below
#define WCHAR_MIN see below
#define WEOF see below

```

The contents and meaning of the header `<wchar>` are the same as the C standard library header `<wchar.h>`, except that it does not declare a type `wchar_t`.

NOTE The functions `wcschr`, `wcspbrk`, `wcsrchr`, `wcsstr`, and `wmemchr` have different signatures in this document, but they have the same behavior as in the C standard library (16.2).

See also ISO/IEC 9899:2018, 7.29.

23.5.5 Header `<cuchar>` synopsis

[`cuchar.syn`]

```

namespace std {
    using mbstate_t = see below;
    using size_t = see 17.2.4;

    size_t mbrtoc8(char8_t* pc8, const char* s, size_t n, mbstate_t* ps);
    size_t c8rtomb(char* s, char8_t c8, mbstate_t* ps);
    size_t mbrtoc16(char16_t* pc16, const char* s, size_t n, mbstate_t* ps);
    size_t c16rtomb(char* s, char16_t c16, mbstate_t* ps);
    size_t mbrtoc32(char32_t* pc32, const char* s, size_t n, mbstate_t* ps);
    size_t c32rtomb(char* s, char32_t c32, mbstate_t* ps);
}

```

The contents and meaning of the header `<cuchar>` are the same as the C standard library header `<uchar.h>`, except that it declares the additional `mbrtoc8` and `c8rtomb` functions and does not declare types `char16_t` nor `char32_t`.

See also ISO/IEC 9899:2018, 7.28.

23.5.6 Multibyte / wide string and character conversion functions

[`c.mb.wcs`]

NOTE The headers `<cstdlib>` (17.2.2), `<cuchar>` (23.5.5), and `<wchar>` (23.5.4) declare the functions described in this subclause.

```

int mbsinit(const mbstate_t* ps);
int mblen(const char* s, size_t n);
size_t mbstowcs(wchar_t* pwcs, const char* s, size_t n);
size_t wcstombs(char* s, const wchar_t* pwcs, size_t n);

```

Effects: These functions have the semantics specified in the C standard library.

See also ISO/IEC 9899:2018, 7.22.7.1, 7.22.8, 7.29.6.2.1.

```

int mbtowc(wchar_t* pwc, const char* s, size_t n);
int wctomb(char* s, wchar_t wchar);

```

Effects: These functions have the semantics specified in the C standard library.

Remarks: Calls to these functions may introduce a data race (16.4.6.10) with other calls to the same function.

See also ISO/IEC 9899:2018, 7.22.7.

```
size_t mbrlen(const char* s, size_t n, mbstate_t* ps);
size_t mbrtowc(wchar_t* pwc, const char* s, size_t n, mbstate_t* ps);
size_t wctomb(char* s, wchar_t wc, mbstate_t* ps);
size_t mbsrtowcs(wchar_t* dst, const char** src, size_t len, mbstate_t* ps);
size_t wcsrtombs(char* dst, const wchar_t** src, size_t len, mbstate_t* ps);
```

Effects: These functions have the semantics specified in the C standard library.

Remarks: Calling these functions with an `mbstate_t*` argument that is a null pointer value may introduce a data race (16.4.6.10) with other calls to the same function with an `mbstate_t*` argument that is a null pointer value.

See also ISO/IEC 9899:2018, 7.29.6.3.

```
size_t mbrtoc8(char8_t* pc8, const char* s, size_t n, mbstate_t* ps);
```

Effects: If `s` is a null pointer, equivalent to `mbrtoc8(nullptr, "", 1, ps)`. Otherwise, the function inspects at most `n` bytes beginning with the byte pointed to by `s` to determine the number of bytes needed to complete the next multibyte character (including any shift sequences). If the function determines that the next multibyte character is complete and valid, it determines the values of the corresponding UTF-8 code units and then, if `pc8` is not a null pointer, stores the value of the first (or only) such code unit in the object pointed to by `pc8`. Subsequent calls will store successive UTF-8 code units without consuming any additional input until all the code units have been stored. If the corresponding Unicode character is U+0000 NULL, the resulting state described is the initial conversion state.

Returns: The first of the following that applies (given the current conversion state):

- 0, if the next `n` or fewer bytes complete the multibyte character that corresponds to the U+0000 NULL Unicode character (which is the value stored).
- between 1 and `n` (inclusive), if the next `n` or fewer bytes complete a valid multibyte character (whose first (or only) code unit is stored); the value returned is the number of bytes that complete the multibyte character.
- `(size_t)(-3)`, if the next code unit resulting from a previous call has been stored (no bytes from the input have been consumed by this call).
- `(size_t)(-2)`, if the next `n` bytes contribute to an incomplete (but potentially valid) multibyte character, and all `n` bytes have been processed (no value is stored).
- `(size_t)(-1)`, if an encoding error occurs, in which case the next `n` or fewer bytes do not contribute to a complete and valid multibyte character (no value is stored); the value of the macro `EILSEQ` is stored in `errno`, and the conversion state is unspecified.

```
size_t c8rtomb(char* s, char8_t c8, mbstate_t* ps);
```

Effects: If `s` is a null pointer, equivalent to `c8rtomb(buf, u8'\0', ps)` where `buf` is an internal buffer. Otherwise, if `c8` completes a sequence of valid UTF-8 code units, determines the number of bytes needed to represent the multibyte character (including any shift sequences), and stores the multibyte character representation in the array whose first element is pointed to by `s`. At most `MB_CUR_MAX` bytes are stored. If the multibyte character is a null character, a null byte is stored, preceded by any shift sequence needed to restore the initial shift state; the resulting state described is the initial conversion state.

Returns: The number of bytes stored in the array object (including any shift sequences). If `c8` does not contribute to a sequence of `char8_t` corresponding to a valid multibyte character, the value of the macro `EILSEQ` is stored in `errno`, `(size_t)(-1)` is returned, and the conversion state is unspecified.

Remarks: Calls to `c8rtomb` with a null pointer argument for `s` may introduce a data race (16.4.6.10) with other calls to `c8rtomb` with a null pointer argument for `s`.

24 Containers library

[containers]

24.1 General

[containers.general]

This Clause describes components that C++ programs may use to organize collections of information.

The following subclauses describe container requirements, and components for sequence containers and associative containers, as summarized in Table 82.

Table 82 — Containers library summary [tab:containers.summary]

Subclause	Header
24.2 Requirements	
24.3 Sequence containers	<array>, <deque>, <forward_list>, <list>, <vector>
24.4 Associative containers	<map>, <set>
24.5 Unordered associative containers	<unordered_map>, <unordered_set>
24.6 Container adaptors	<queue>, <stack>, <flat_map>, <flat_set>
24.7 Views	, <mdspan>

24.2 Requirements

[container.requirements]

24.2.1 Preamble

[container.requirements.pre]

Containers are objects that store other objects. They control allocation and deallocation of these objects through constructors, destructors, insert and erase operations.

All of the complexity requirements in this Clause are stated solely in terms of the number of operations on the contained objects.

EXAMPLE The copy constructor of type `vector<vector<int>>` has linear complexity, even though the complexity of copying each contained `vector<int>` is itself linear.

Allocator-aware containers (24.2.2.5) other than `basic_string` construct elements using the function `allocator_traits<allocator_type>::rebind_traits<U>::construct` and destroy elements using the function `allocator_traits<allocator_type>::rebind_traits<U>::destroy` (20.2.9.3), where `U` is either `allocator_type::value_type` or an internal type used by the container. These functions are called only for the container's element type, not for internal types used by the container.

NOTE This means, for example, that a node-based container would need to construct nodes containing aligned buffers and call `construct` to place the element into the buffer.

24.2.2 General containers

[container.requirements.general]

24.2.2.1 Introduction

[container.intro.reqmts]

In 24.2.2,

- `X` denotes a container class containing objects of type `T`,
- `a` denotes a value of type `X`,
- `b` and `c` denote values of type (possibly `const`) `X`,
- `i` and `j` denote values of type (possibly `const`) `X::iterator`,
- `u` denotes an identifier,
- `v` denotes an lvalue of type (possibly `const`) `X` or an rvalue of type `const X`,
- `s` and `t` denote non-`const` lvalues of type `X`, and
- `rv` denotes a non-`const` rvalue of type `X`.

The following exposition-only concept is used in the definition of containers:

```
template<class R, class T>
concept container-compatible-range = // exposition only
    ranges::input_range<R> && convertible_to<ranges::range_reference_t<R>, T>;
```

24.2.2.2 Container requirements

[container.reqmts]

A type *X* meets the *container* requirements if the following types, statements, and expressions are well-formed and have the specified semantics.

typename *X*::value_type

Result: *T*

Preconditions: *T* is *Cpp17Erasable* from *X* (see 24.2.2.5, below).

typename *X*::reference

Result: *T*&

typename *X*::const_reference

Result: const *T*&

typename *X*::iterator

Result: A type that meets the forward iterator requirements (25.3.5.5) with value type *T*. The type *X*::iterator is convertible to *X*::const_iterator.

typename *X*::const_iterator

Result: A type that meets the requirements of a constant iterator and those of a forward iterator with value type *T*.

typename *X*::difference_type

Result: A signed integer type, identical to the difference type of *X*::iterator and *X*::const_iterator.

typename *X*::size_type

Result: An unsigned integer type that can represent any non-negative value of *X*::difference_type.

X u;

X u = *X*();

Postconditions: u.empty()

Complexity: Constant.

X u(*v*);

X u = *v*;

Preconditions: *T* is *Cpp17CopyInsertable* into *X* (see below).

Postconditions: u == *v*

Complexity: Linear.

X u(*rv*);

X u = *rv*;

Postconditions: u is equal to the value that *rv* had before this construction.

Complexity: Linear for **array** and constant for all other standard containers.

t = *v*;

Result: *X*&.

Postconditions: *t* == *v*.

Complexity: Linear.

t = *rv*

Result: *X*&.

Effects: All existing elements of *t* are either move assigned to or destroyed.

Postconditions: If *t* and *rv* do not refer to the same object, *t* is equal to the value that *rv* had before this assignment.

Complexity: Linear.

a. ~X()

Result: void.

Effects: Destroys every element of **a**; any memory obtained is deallocated.

Complexity: Linear.

b.begin()

Result: iterator; const_iterator for constant **b**.

Returns: An iterator referring to the first element in the container.

Complexity: Constant.

b.end()

Result: iterator; const_iterator for constant **b**.

Returns: An iterator which is the past-the-end value for the container.

Complexity: Constant.

b.cbegin()

Result: const_iterator.

Returns: const_cast<X const&>(b).begin()

Complexity: Constant.

b.cend()

Result: const_iterator.

Returns: const_cast<X const&>(b).end()

Complexity: Constant.

i <=> j

Result: strong_ordering.

Constraints: X::iterator meets the random access iterator requirements.

Complexity: Constant.

c == b

Preconditions: T meets the Cpp17EqualityComparable requirements.

Result: bool.

Returns: equal(c.begin(), c.end(), b.begin(), b.end())

NOTE 1 The algorithm equal is defined in 27.6.13.

Complexity: Constant if c.size() != b.size(), linear otherwise.

Remarks: == is an equivalence relation.

c != b

Effects: Equivalent to !(c == b).

t.swap(s)

Result: void.

Effects: Exchanges the contents of **t** and **s**.

Complexity: Linear for array and constant for all other standard containers.

swap(t, s)

Effects: Equivalent to t.swap(s).

c.size()

Result: size_type.

Returns: `distance(c.begin(), c.end())`, i.e., the number of elements in the container.

Complexity: Constant.

Remarks: The number of elements is defined by the rules of constructors, inserts, and erases.

`c.max_size()`

Result: `size_type`.

Returns: `distance(begin(), end())` for the largest possible container.

Complexity: Constant.

`c.empty()`

Result: `bool`.

Returns: `c.begin() == c.end()`

Complexity: Constant.

Remarks: If the container is empty, then `c.empty()` is `true`.

In the expressions

```
i == j
i != j
i < j
i <= j
i >= j
i > j
i <=> j
i - j
```

where `i` and `j` denote objects of a container's `iterator` type, either or both may be replaced by an object of the container's `const_iterator` type referring to the same element with no change in semantics.

Unless otherwise specified, all containers defined in this Clause obtain memory using an allocator (see 16.4.4.6).

NOTE 2 In particular, containers and iterators do not store references to allocated elements other than through the allocator's pointer type, i.e., as objects of type `P` or `pointer_traits<P>::template rebind<unspecified>`, where `P` is `allocator_traits<allocator_type>::pointer`.

Copy constructors for these container types obtain an allocator by calling `allocator_traits<allocator_type>::select_on_container_copy_construction` on the allocator belonging to the container being copied. Move constructors obtain an allocator by move construction from the allocator belonging to the container being moved. Such move construction of the allocator shall not exit via an exception. All other constructors for these container types take a `const allocator_type&` argument.

NOTE 3 Invocation of a constructor that uses the default value of an optional allocator argument is ill-formed unless the allocator type supports value-initialization.

A copy of this allocator is used for any memory allocation and element construction performed, by these constructors and by all member functions, during the lifetime of each container object or until the allocator is replaced. The allocator may be replaced only via assignment or `swap()`. Allocator replacement is performed by copy assignment, move assignment, or swapping of the allocator only if

- `allocator_traits<allocator_type>::propagate_on_container_copy_assignment::value`,
- `allocator_traits<allocator_type>::propagate_on_container_move_assignment::value`, or
- `allocator_traits<allocator_type>::propagate_on_container_swap::value`

is `true` within the implementation of the corresponding container operation. In all container types defined in this Clause, the member `get_allocator()` returns a copy of the allocator used to construct the container or, if that allocator has been replaced, a copy of the most recent replacement.

The expression `a.swap(b)`, for containers `a` and `b` of a standard container type other than `array`, shall exchange the values of `a` and `b` without invoking any move, copy, or swap operations on the individual container elements. Any `Compare`, `Pred`, or `Hash` types belonging to `a` and `b` shall meet the *Cpp17Swappable* requirements and shall be exchanged by calling `swap` as described in 16.4.4.3. If `allocator_traits<allocator_type>::propagate_on_container_swap::value` is `true`, then `allocator_type` shall meet the *Cpp17Swappable* requirements and the allocators of `a` and `b` shall also be exchanged by calling `swap` as described in 16.4.4.3.

Otherwise, the allocators shall not be swapped, and the behavior is undefined unless `a.get_allocator() == b.get_allocator()`. Every iterator referring to an element in one container before the swap shall refer to the same element in the other container after the swap. It is unspecified whether an iterator with value `a.end()` before the swap will have value `b.end()` after the swap.

Unless otherwise specified (see 24.2.7.2, 24.2.8.2, 24.3.8.4, and 24.3.11.5) all container types defined in this Clause meet the following additional requirements:

- If an exception is thrown by an `insert()` or `emplace()` function while inserting a single element, that function has no effects.
- If an exception is thrown by a `push_back()`, `push_front()`, `emplace_back()`, or `emplace_front()` function, that function has no effects.
- No `erase()`, `clear()`, `pop_back()` or `pop_front()` function throws an exception.
- No copy constructor or assignment operator of a returned iterator throws an exception.
- No `swap()` function throws an exception.
- No `swap()` function invalidates any references, pointers, or iterators referring to the elements of the containers being swapped.

NOTE 4 The `end()` iterator does not refer to any element, so it can be invalidated.

Unless otherwise specified (either explicitly or by defining a function in terms of other functions), invoking a container member function or passing a container as an argument to a library function shall not invalidate iterators to, or change the values of, objects within that container.

A *contiguous container* is a container whose member types `iterator` and `const_iterator` meet the *Cpp17RandomAccessIterator* requirements (25.3.5.7) and model `contiguous_iterator` (25.3.4.14).

The behavior of certain container member functions and deduction guides depends on whether types qualify as input iterators or allocators. The extent to which an implementation determines that a type cannot be an input iterator is unspecified, except that as a minimum integral types shall not qualify as input iterators. Likewise, the extent to which an implementation determines that a type cannot be an allocator is unspecified, except that as a minimum a type `A` shall not qualify as an allocator unless it meets both of the following conditions:

- The *qualified-id* `A::value_type` is valid and denotes a type (13.10.3).
- The expression `declval<A&>().allocate(size_t{})` is well-formed when treated as an unevaluated operand.

24.2.2.3 Reversible container requirements

[container.rev.reqmts]

A type `X` meets the *reversible container* requirements if `X` meets the container requirements, the iterator type of `X` belongs to the bidirectional or random access iterator categories (25.3), and the following types and expressions are well-formed and have the specified semantics.

`typename X::reverse_iterator`

Result: The type `reverse_iterator<X::iterator>`, an iterator type whose value type is `T`.

`typename X::const_reverse_iterator`

Result: The type `reverse_iterator<X::const_iterator>`, a constant iterator type whose value type is `T`.

`a.rbegin()`

Result: `reverse_iterator`; `const_reverse_iterator` for constant `a`.

Returns: `reverse_iterator(end())`

Complexity: Constant.

`a.rend()`

Result: `reverse_iterator`; `const_reverse_iterator` for constant `a`.

Returns: `reverse_iterator(begin())`

Complexity: Constant.

a.crbegin()

Result: `const_reverse_iterator`.

Returns: `const_cast<X const&>(a).rbegin()`

Complexity: Constant.

a.crend()

Result: `const_reverse_iterator`.

Returns: `const_cast<X const&>(a).rend()`

Complexity: Constant.

24.2.2.4 Optional container requirements

[container.opt.reqmts]

The following operations are provided for some types of containers but not others. Those containers for which the listed operations are provided shall implement the semantics as described unless otherwise stated. If the iterators passed to `lexicographical_compare_three_way` meet the `constexpr` iterator requirements (25.3.1) then the operations described below are implemented by `constexpr` functions.

a <=> b

Result: `synth-three-way-result<X::value_type>`.

Preconditions: Either `<=>` is defined for values of type (possibly `const`) `T`, or `<` is defined for values of type (possibly `const`) `T` and `<` is a total ordering relationship.

Returns: `lexicographical_compare_three_way(a.begin(), a.end(), b.begin(), b.end(), synth-three-way)`

NOTE The algorithm `lexicographical_compare_three_way` is defined in Clause 27.

Complexity: Linear.

24.2.2.5 Allocator-aware containers

[container.alloc.reqmts]

All of the containers defined in Clause 24 and in 23.4.3 except `array` meet the additional requirements of an *allocator-aware container*, as described below.

Given an allocator type `A` and given a container type `X` having a `value_type` identical to `T` and an `allocator_type` identical to `allocator_traits<A>::rebind_alloc<T>` and given an lvalue `m` of type `A`, a pointer `p` of type `T*`, an expression `v` of type `T` or `const T`, and an rvalue `rv` of type `T`, the following terms are defined. If `X` is not allocator-aware or is a specialization of `basic_string`, the terms below are defined as if `A` were `allocator<T>` — no allocator object needs to be created and user specializations of `allocator<T>` are not instantiated:

- `T` is *Cpp17DefaultInsertable into X* means that the following expression is well-formed:

`allocator_traits<A>::construct(m, p)`

- An element of `X` is *default-inserted* if it is initialized by evaluation of the expression

`allocator_traits<A>::construct(m, p)`

where `p` is the address of the uninitialized storage for the element allocated within `X`.

- `T` is *Cpp17MoveInsertable into X* means that the following expression is well-formed:

`allocator_traits<A>::construct(m, p, rv)`

and its evaluation causes the following postcondition to hold: The value of `*p` is equivalent to the value of `rv` before the evaluation.

NOTE 1 `rv` remains a valid object. Its state is unspecified

- `T` is *Cpp17CopyInsertable into X* means that, in addition to `T` being *Cpp17MoveInsertable into X*, the following expression is well-formed:

`allocator_traits<A>::construct(m, p, v)`

and its evaluation causes the following postcondition to hold: The value of `v` is unchanged and is equivalent to `*p`.

- *T* is *Cpp17EmplaceConstructible* into *X* from *args*, for zero or more arguments *args*, means that the following expression is well-formed:

`allocator_traits<A>::construct(m, p, args)`

- *T* is *Cpp17Erasable* from *X* means that the following expression is well-formed:

`allocator_traits<A>::destroy(m, p)`

NOTE 2 A container calls `allocator_traits<A>::construct(m, p, args)` to construct an element at *p* using *args*, with *m* == `get_allocator()`. The default `construct` in `allocator` will call `::new((void*)p) T(args)`, but specialized allocators can choose a different definition.

In this subclause,

- *X* denotes an allocator-aware container class with a `value_type` of *T* using an allocator of type *A*,
- *u* denotes a variable,
- *a* and *b* denote non-const lvalues of type *X*,
- *c* denotes an lvalue of type `const X`,
- *t* denotes an lvalue or a const rvalue of type *X*,
- *rv* denotes a non-const rvalue of type *X*, and
- *m* is a value of type *A*.

A type *X* meets the allocator-aware container requirements if *X* meets the container requirements and the following types, statements, and expressions are well-formed and have the specified semantics.

`typename X::allocator_type`

Result: *A*

Mandates: `allocator_type::value_type` is the same as `X::value_type`.

`c.get_allocator()`

Result: *A*

Complexity: Constant.

`X u;`

`X u = X();`

Preconditions: *A* meets the *Cpp17DefaultConstructible* requirements.

Postconditions: `u.empty()` returns `true`, `u.get_allocator() == A()`.

Complexity: Constant.

`X u(m);`

Postconditions: `u.empty()` returns `true`, `u.get_allocator() == m`.

Complexity: Constant.

`X u(t, m);`

Preconditions: *T* is *Cpp17CopyInsertable* into *X*.

Postconditions: `u == t`, `u.get_allocator() == m`

Complexity: Linear.

`X u(rv);`

Postconditions: *u* has the same elements as *rv* had before this construction; the value of `u.get_allocator()` is the same as the value of `rv.get_allocator()` before this construction.

Complexity: Constant.

`X u(rv, m);`

Preconditions: *T* is *Cpp17MoveInsertable* into *X*.

Postconditions: *u* has the same elements, or copies of the elements, that *rv* had before this construction, `u.get_allocator() == m`.

Complexity: Constant if `m == rv.get_allocator()`, otherwise linear.

`a = t`

Result: `X&`.

Preconditions: `T` is *Cpp17CopyInsertable* into `X` and *Cpp17CopyAssignable*.

Postconditions: `a == t` is `true`.

Complexity: Linear.

`a = rv`

Result: `X&`.

Preconditions: If

`allocator_traits<allocator_type>::propagate_on_container_move_assignment::value` is `false`, `T` is *Cpp17MoveInsertable* into `X` and *Cpp17MoveAssignable*.

Effects: All existing elements of `a` are either move assigned to or destroyed.

Postconditions: If `a` and `rv` do not refer to the same object, `a` is equal to the value that `rv` had before this assignment.

Complexity: Linear.

`a.swap(b)`

Result: `void`

Effects: Exchanges the contents of `a` and `b`.

Complexity: Constant.

24.2.3 Container data races

[`container.requirements.dataraces`]

For purposes of avoiding data races (16.4.6.10), implementations shall consider the following functions to be `const`: `begin`, `end`, `rbegin`, `rend`, `front`, `back`, `data`, `find`, `lower_bound`, `upper_bound`, `equal_range`, `at` and, except in associative or unordered associative containers, `operator[]`.

Notwithstanding 16.4.6.10, implementations are required to avoid data races when the contents of the contained object in different elements in the same container, excepting `vector<bool>`, are modified concurrently.

NOTE For a `vector<int>` `x` with a size greater than one, `x[1] = 5` and `*x.begin() = 10` can be executed concurrently without a data race, but `x[0] = 5` and `*x.begin() = 10` executed concurrently can result in a data race. As an exception to the general rule, for a `vector<bool>` `y`, `y[0] = true` can race with `y[1] = true`.

24.2.4 Sequence containers

[`sequence.reqmts`]

A sequence container organizes a finite set of objects, all of the same type, into a strictly linear arrangement. The library provides four basic kinds of sequence containers: `vector`, `forward_list`, `list`, and `deque`. In addition, `array` is provided as a sequence container which provides limited sequence operations because it has a fixed number of elements. The library also provides container adaptors that make it easy to construct abstract data types, such as `stacks`, `queues`, `flat_maps`, `flat_multimaps`, `flat_sets`, or `flat_multisets`, out of the basic sequence container kinds (or out of other program-defined sequence containers).

In this subclause,

- `X` denotes a sequence container class,
- `a` denotes a value of type `X` containing elements of type `T`,
- `u` denotes the name of a variable being declared,
- `A` denotes `X::allocator_type` if the *qualified-id* `X::allocator_type` is valid and denotes a type (13.10.3) and `allocator<T>` if it doesn't,
- `i` and `j` denote iterators that meet the *Cpp17InputIterator* requirements and refer to elements implicitly convertible to `value_type`,
- `[i, j)` denotes a valid range,
- `rg` denotes a value of a type `R` that models *container-compatible-range<T>*,
- `il` designates an object of type `initializer_list<value_type>`,

- `n` denotes a value of type `X::size_type`,
- `p` denotes a valid constant iterator to `a`,
- `q` denotes a valid dereferenceable constant iterator to `a`,
- `[q1, q2)` denotes a valid range of constant iterators in `a`,
- `t` denotes an lvalue or a const rvalue of `X::value_type`, and
- `rv` denotes a non-const rvalue of `X::value_type`.
- `Args` denotes a template parameter pack;
- `args` denotes a function parameter pack with the pattern `Args&&`.

The complexities of the expressions are sequence dependent.

A type `X` meets the *sequence container* requirements if `X` meets the container requirements and the following statements and expressions are well-formed and have the specified semantics.

`X u(n, t);`

Preconditions: `T` is *Cpp17CopyInsertable* into `X`.

Effects: Constructs a sequence container with `n` copies of `t`.

Postconditions: `distance(u.begin(), u.end()) == n` is true.

`X u(i, j);`

Preconditions: `T` is *Cpp17EmplaceConstructible* into `X` from `*i`. For *vector*, if the iterator does not meet the *Cpp17ForwardIterator* requirements (25.3.5.5), `T` is also *Cpp17MoveInsertable* into `X`.

Effects: Constructs a sequence container equal to the range `[i, j)`. Each iterator in the range `[i, j)` is dereferenced exactly once.

Postconditions: `distance(u.begin(), u.end()) == distance(i, j)` is true.

`X(from_range, rg)`

Preconditions: `T` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`. For *vector*, if `R` models neither `ranges::sized_range` nor `ranges::forward_range`, `T` is also *Cpp17MoveInsertable* into `X`.

Effects: Constructs a sequence container equal to the range `rg`. Each iterator in the range `rg` is dereferenced exactly once.

Postconditions: `distance(begin(), end()) == ranges::distance(rg)` is true.

`X(il)`

Effects: Equivalent to `X(il.begin(), il.end())`.

`a = il`

Result: `X&`.

Preconditions: `T` is *Cpp17CopyInsertable* into `X` and *Cpp17CopyAssignable*.

Effects: Assigns the range `[il.begin(), il.end())` into `a`. All existing elements of `a` are either assigned to or destroyed.

Returns: `*this`.

`a.emplace(p, args)`

Result: *iterator*.

Preconditions: `T` is *Cpp17EmplaceConstructible* into `X` from `args`. For *vector* and *deque*, `T` is also *Cpp17MoveInsertable* into `X` and *Cpp17MoveAssignable*.

Effects: Inserts an object of type `T` constructed with `std::forward<Args>(args)...` before `p`.

NOTE 1 `args` can directly or indirectly refer to a value in `a`.

Returns: An iterator that points to the new element constructed from `args` into `a`.

a.insert(p, t)

Result: iterator.

Preconditions: T is *Cpp17CopyInsertable* into X. For **vector** and **deque**, T is also *Cpp17CopyAssignable*.

Effects: Inserts a copy of **t** before **p**.

Returns: An iterator that points to the copy of **t** inserted into **a**.

a.insert(p, rv)

Result: iterator.

Preconditions: T is *Cpp17MoveInsertable* into X. For **vector** and **deque**, T is also *Cpp17MoveAssignable*.

Effects: Inserts a copy of **rv** before **p**.

Returns: An iterator that points to the copy of **rv** inserted into **a**.

a.insert(p, n, t)

Result: iterator.

Preconditions: T is *Cpp17CopyInsertable* into X and *Cpp17CopyAssignable*.

Effects: Inserts **n** copies of **t** before **p**.

Returns: An iterator that points to the copy of the first element inserted into **a**, or **p** if **n** == 0.

a.insert(p, i, j)

Result: iterator.

Preconditions: T is *Cpp17EmplaceConstructible* into X from ***i**. For **vector** and **deque**, T is also *Cpp17MoveInsertable* into X, and T meets the *Cpp17MoveConstructible*, *Cpp17MoveAssignable*, and *Cpp17Swappable* (16.4.4.3) requirements. Neither **i** nor **j** are iterators into **a**.

Effects: Inserts copies of elements in **[i, j)** before **p**. Each iterator in the range **[i, j)** shall be dereferenced exactly once.

Returns: An iterator that points to the copy of the first element inserted into **a**, or **p** if **i** == **j**.

a.insert_range(p, rg)

Result: iterator.

Preconditions: T is *Cpp17EmplaceConstructible* into X from ***ranges::begin(rg)**. For **vector** and **deque**, T is also *Cpp17MoveInsertable* into X, and T meets the *Cpp17MoveConstructible*, *Cpp17MoveAssignable*, and *Cpp17Swappable* (16.4.4.3) requirements. **rg** and **a** do not overlap.

Effects: Inserts copies of elements in **rg** before **p**. Each iterator in the range **rg** is dereferenced exactly once.

Returns: An iterator that points to the copy of the first element inserted into **a**, or **p** if **rg** is empty.

a.insert(p, il)

Effects: Equivalent to **a.insert(p, il.begin(), il.end())**.

a.erase(q)

Result: iterator.

Preconditions: For **vector** and **deque**, T is *Cpp17MoveAssignable*.

Effects: Erases the element pointed to by **q**.

Returns: An iterator that points to the element immediately following **q** prior to the element being erased. If no such element exists, **a.end()** is returned.

a.erase(q1, q2)

Result: iterator.

Preconditions: For **vector** and **deque**, T is *Cpp17MoveAssignable*.

Effects: Erases the elements in the range **[q1, q2)**.

Returns: An iterator that points to the element pointed to by `q2` prior to any elements being erased. If no such element exists, `a.end()` is returned.

`a.clear()`

Result: `void`

Effects: Destroys all elements in `a`. Invalidates all references, pointers, and iterators referring to the elements of `a` and may invalidate the past-the-end iterator.

Postconditions: `a.empty()` is `true`.

Complexity: Linear.

`a.assign(i, j)`

Result: `void`

Preconditions: `T` is *Cpp17EmplaceConstructible* into `X` from `*i` and assignable from `*i`. For `vector`, if the iterator does not meet the forward iterator requirements (25.3.5.5), `T` is also *Cpp17MoveInsertable* into `X`. Neither `i` nor `j` are iterators into `a`.

Effects: Replaces elements in `a` with a copy of `[i, j)`. Invalidates all references, pointers and iterators referring to the elements of `a`. For `vector` and `deque`, also invalidates the past-the-end iterator. Each iterator in the range `[i, j)` is dereferenced exactly once.

`a.assign_range(rg)`

Result: `void`

Mandates: `assignable_from<T&, ranges::range_reference_t<R>>` is modeled.

Preconditions: `T` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`. For `vector`, if `R` models neither `ranges::sized_range` nor `ranges::forward_range`, `T` is also *Cpp17MoveInsertable* into `X`. `rg` and `a` do not overlap.

Effects: Replaces elements in `a` with a copy of each element in `rg`. Invalidates all references, pointers, and iterators referring to the elements of `a`. For `vector` and `deque`, also invalidates the past-the-end iterator. Each iterator in the range `rg` is dereferenced exactly once.

`a.assign(il)`

Effects: Equivalent to `a.assign(il.begin(), il.end())`.

`a.assign(n, t)`

Result: `void`

Preconditions: `T` is *Cpp17CopyInsertable* into `X` and *Cpp17CopyAssignable*. `t` is not a reference into `a`.

Effects: Replaces elements in `a` with `n` copies of `t`. Invalidates all references, pointers and iterators referring to the elements of `a`. For `vector` and `deque`, also invalidates the past-the-end iterator.

For every sequence container defined in this Clause and in [Clause 23](#):

- If the constructor

```
template<class InputIterator>
X(InputIterator first, InputIterator last,
  const allocator_type& alloc = allocator_type());
```

is called with a type `InputIterator` that does not qualify as an input iterator, then the constructor shall not participate in overload resolution.

- If the member functions of the forms:

```
template<class InputIterator>
return-type F(const_iterator p,
              InputIterator first, InputIterator last);           // such as insert

template<class InputIterator>
return-type F(InputIterator first, InputIterator last);           // such as append, assign
```

```
template<class InputIterator>
    return-type F(const_iterator i1, const_iterator i2,
                  InputIterator first, InputIterator last);    // such as replace
```

are called with a type `InputIterator` that does not qualify as an input iterator, then these functions shall not participate in overload resolution.

- A deduction guide for a sequence container shall not participate in overload resolution if it has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter, or if it has an `Allocator` template parameter and a type that does not qualify as an allocator is deduced for that parameter.

The following operations are provided for some types of sequence containers but not others. Operations other than `prepend_range` and `append_range` are implemented so as to take amortized constant time.

`a.front()`

Result: reference; const_reference for constant a.

Returns: `*a.begin()`

Remarks: Required for `basic_string`, `array`, `deque`, `forward_list`, `list`, and `vector`.

`a.back()`

Result: reference; const_reference for constant a.

Effects: Equivalent to:

```
auto tmp = a.end();
--tmp;
return *tmp;
```

Remarks: Required for `basic_string`, `array`, `deque`, `list`, and `vector`.

`a.emplace_front(args)`

Result: reference

Preconditions: T is `Cpp17EmplaceConstructible` into X from args.

Effects: Prepends an object of type T constructed with `std::forward<Args>(args)...`

Returns: `a.front()`.

Remarks: Required for `deque`, `forward_list`, and `list`.

`a.emplace_back(args)`

Result: reference

Preconditions: T is `Cpp17EmplaceConstructible` into X from args. For `vector`, T is also `Cpp17MoveInsertable` into X.

Effects: Appends an object of type T constructed with `std::forward<Args>(args)...`

Returns: `a.back()`.

Remarks: Required for `deque`, `list`, and `vector`.

`a.push_front(t)`

Result: void

Preconditions: T is `Cpp17CopyInsertable` into X.

Effects: Prepends a copy of t.

Remarks: Required for `deque`, `forward_list`, and `list`.

`a.push_front(rv)`

Result: void

Preconditions: T is `Cpp17MoveInsertable` into X.

Effects: Prepends a copy of rv.

Remarks: Required for `deque`, `forward_list`, and `list`.

a.prepend_range(rg)*Result:* void*Preconditions:* T is *Cpp17EmplaceConstructible* into X from **ranges::begin(rg)*. For *deque*, T is also *Cpp17MoveInsertable* into X, and T meets the *Cpp17MoveConstructible*, *Cpp17MoveAssignable*, and *Cpp17Swappable* (16.4.4.3) requirements.*Effects:* Inserts copies of elements in *rg* before *begin()*. Each iterator in the range *rg* is dereferenced exactly once.NOTE 2 The order of elements in *rg* is not reversed.*Remarks:* Required for *deque*, *forward_list*, and *list*.**a.push_back(t)***Result:* void*Preconditions:* T is *Cpp17CopyInsertable* into X.*Effects:* Appends a copy of *t*.*Remarks:* Required for *basic_string*, *deque*, *list*, and *vector*.**a.push_back(rv)***Result:* void*Preconditions:* T is *Cpp17MoveInsertable* into X.*Effects:* Appends a copy of *rv*.*Remarks:* Required for *basic_string*, *deque*, *list*, and *vector*.**a.append_range(rg)***Result:* void*Preconditions:* T is *Cpp17EmplaceConstructible* into X from **ranges::begin(rg)*. For *vector*, T is also *Cpp17MoveInsertable* into X.*Effects:* Inserts copies of elements in *rg* before *end()*. Each iterator in the range *rg* is dereferenced exactly once.*Remarks:* Required for *deque*, *list*, and *vector*.**a.pop_front()***Result:* void*Preconditions:* *a.empty()* is false.*Effects:* Destroys the first element.*Remarks:* Required for *deque*, *forward_list*, and *list*.**a.pop_back()***Result:* void*Preconditions:* *a.empty()* is false.*Effects:* Destroys the last element.*Remarks:* Required for *basic_string*, *deque*, *list*, and *vector*.**a[n]***Result:* reference; *const_reference* for constant *a**Returns:* **(a.begin() + n)**Remarks:* Required for *basic_string*, *array*, *deque*, and *vector*.**a.at(n)***Result:* reference; *const_reference* for constant *a**Returns:* **(a.begin() + n)*

Throws: `out_of_range` if `n >= a.size()`.

Remarks: Required for `basic_string`, `array`, `deque`, and `vector`.

24.2.5 Node handles

[container.node]

24.2.5.1 Overview

[container.node.overview]

A *node handle* is an object that accepts ownership of a single element from an associative container (24.2.7) or an unordered associative container (24.2.8). It may be used to transfer that ownership to another container with compatible nodes. Containers with compatible nodes have the same node handle type. Elements may be transferred in either direction between container types in the same row of Table 83.

Table 83 — Container types with compatible nodes [tab:container.node.compat]

<code>map<K, T, C1, A></code>	<code>map<K, T, C2, A></code>
<code>map<K, T, C1, A></code>	<code>multimap<K, T, C2, A></code>
<code>set<K, C1, A></code>	<code>set<K, C2, A></code>
<code>set<K, C1, A></code>	<code>multiset<K, C2, A></code>
<code>unordered_map<K, T, H1, E1, A></code>	<code>unordered_map<K, T, H2, E2, A></code>
<code>unordered_map<K, T, H1, E1, A></code>	<code>unordered_multimap<K, T, H2, E2, A></code>
<code>unordered_set<K, H1, E1, A></code>	<code>unordered_set<K, H2, E2, A></code>
<code>unordered_set<K, H1, E1, A></code>	<code>unordered_multiset<K, H2, E2, A></code>

If a node handle is not empty, then it contains an allocator that is equal to the allocator of the container when the element was extracted. If a node handle is empty, it contains no allocator.

Class *node-handle* is for exposition only.

If a user-defined specialization of `pair` exists for `pair<const Key, T>` or `pair<Key, T>`, where `Key` is the container's `key_type` and `T` is the container's `mapped_type`, the behavior of operations involving node handles is undefined.

```
template<unspecified>
class node-handle {
public:
    // These type declarations are described in 24.2.7 and 24.2.8.
    using value_type      = see below;           // not present for map containers
    using key_type        = see below;           // not present for set containers
    using mapped_type     = see below;           // not present for set containers
    using allocator_type  = see below;

private:
    using container_node_type = unspecified;           // exposition only
    using ator_traits = allocator_traits<allocator_type>; // exposition only

    typename ator_traits::template
        rebind_traits<container_node_type>::pointer ptr_; // exposition only
    optional<allocator_type> alloc_; // exposition only

public:
    // 24.2.5.2, constructors, copy, and assignment
    constexpr node-handle() noexcept : ptr_(), alloc_() {}
    node-handle(node-handle&&) noexcept;
    node-handle& operator=(node-handle&&);

    // 24.2.5.3, destructor
    ~node-handle();

    // 24.2.5.4, observers
    value_type& value() const;           // not present for map containers
    key_type& key() const;               // not present for set containers
    mapped_type& mapped() const;         // not present for set containers
}
```

```

allocator_type get_allocator() const;
explicit operator bool() const noexcept;
[[nodiscard]] bool empty() const noexcept;

// 24.2.5.5, modifiers
void swap(node-handle&& nh) noexcept(
    noexcept(ator_traits::propagate_on_container_swap::value ||
        ator_traits::is_always_equal::value));

friend void swap(node-handle& x, node-handle& y) noexcept(noexcept(x.swap(y))) {
    x.swap(y);
}
};

```

24.2.5.2 Constructors, copy, and assignment

[container.node.cons]

node-handle(*node-handle&& nh*) noexcept;

Effects: Constructs a *node-handle* object initializing *ptr_* with *nh.ptr_*. Move constructs *alloc_* with *nh.alloc_*. Assigns *nullptr* to *nh.ptr_* and assigns *nullopt* to *nh.alloc_*.

node-handle& operator=(*node-handle&& nh*);

Preconditions: Either !*alloc_*, or *ator_traits::propagate_on_container_move_assignment::value* is true, or *alloc_ == nh.alloc_*.

Effects:

- If *ptr_ != nullptr*, destroys the *value_type* subobject in the *container_node_type* object pointed to by *ptr_* by calling *ator_traits::destroy*, then deallocates *ptr_* by calling *ator_traits::template rebind_traits<container_node_type>::deallocate*.
- Assigns *nh.ptr_* to *ptr_*.
- If !*alloc_* or *ator_traits::propagate_on_container_move_assignment::value* is true, move assigns *nh.alloc_* to *alloc_*.
- Assigns *nullptr* to *nh.ptr_* and assigns *nullopt* to *nh.alloc_*.

Returns: **this*.

Throws: Nothing.

24.2.5.3 Destructor

[container.node.dtor]

~node-handle();

Effects: If *ptr_ != nullptr*, destroys the *value_type* subobject in the *container_node_type* object pointed to by *ptr_* by calling *ator_traits::destroy*, then deallocates *ptr_* by calling *ator_traits::template rebind_traits<container_node_type>::deallocate*.

24.2.5.4 Observers

[container.node.observers]

value_type& value() const;

Preconditions: *empty()* == false.

Returns: A reference to the *value_type* subobject in the *container_node_type* object pointed to by *ptr_*.

Throws: Nothing.

key_type& key() const;

Preconditions: *empty()* == false.

Returns: A non-const reference to the *key_type* member of the *value_type* subobject in the *container_node_type* object pointed to by *ptr_*.

Throws: Nothing.

Remarks: Modifying the key through the returned reference is permitted.

mapped_type& mapped() const;

Preconditions: empty() == false.

Returns: A reference to the mapped_type member of the value_type subobject in the container_node_type object pointed to by ptr_.

Throws: Nothing.

allocator_type get_allocator() const;

Preconditions: empty() == false.

Returns: *alloc_.

Throws: Nothing.

explicit operator bool() const noexcept;

Returns: ptr_ != nullptr.

[[nodiscard]] bool empty() const noexcept;

Returns: ptr_ == nullptr.

24.2.5.5 Modifiers

[container.node.modifiers]

void swap(node_handle& nh)

noexcept(ator_traits::propagate_on_container_swap::value ||
ator_traits::is_always_equal::value);

Preconditions: !alloc_, or !nh.alloc_, or ator_traits::propagate_on_container_swap::value is true, or alloc_ == nh.alloc_.

Effects: Calls swap(ptr_, nh.ptr_). If !alloc_, or !nh.alloc_, or ator_traits::propagate_on_container_swap::value is true calls swap(alloc_, nh.alloc_).

24.2.6 Insert return type

[container.insert.return]

The associative containers with unique keys and the unordered containers with unique keys have a member function **insert** that returns a nested type **insert_return_type**. That return type is a specialization of the template specified in this subclause.

```
template<class Iterator, class NodeType>
struct insert_return_type
{
    Iterator position;
    bool inserted;
    NodeType node;
};
```

The name *insert_return_type* is exposition only. *insert_return_type* has the template parameters, data members, and special members specified above. It has no base classes or members other than those specified.

24.2.7 Associative containers

[associative.reqmts]

24.2.7.1 General

[associative.reqmts.general]

Associative containers provide fast retrieval of data based on keys. The library provides four basic kinds of associative containers: **set**, **multiset**, **map** and **multimap**. The library also provides container adaptors that make it easy to construct abstract data types, such as **flat_maps**, **flat_multimaps**, **flat_sets**, or **flat_multisets**, out of the basic sequence container kinds (or out of other program-defined sequence containers).

Each associative container is parameterized on **Key** and an ordering relation **Compare** that induces a strict weak ordering (27.8) on elements of **Key**. In addition, **map** and **multimap** associate an arbitrary *mapped type* **T** with the **Key**. The object of type **Compare** is called the *comparison object* of a container.

The phrase “equivalence of keys” means the equivalence relation imposed by the comparison object. That is, two keys **k1** and **k2** are considered to be equivalent if for the comparison object **comp**, **comp(k1, k2) == false && comp(k2, k1) == false**.

NOTE 1 This is not necessarily the same as the result of `k1 == k2`.

For any two keys `k1` and `k2` in the same container, calling `comp(k1, k2)` shall always return the same value.

An associative container supports *unique keys* if it may contain at most one element for each key. Otherwise, it supports *equivalent keys*. The `set` and `map` classes support unique keys; the `multiset` and `multimap` classes support equivalent keys. For `multiset` and `multimap`, `insert`, `emplace`, and `erase` preserve the relative ordering of equivalent elements.

For `set` and `multiset` the value type is the same as the key type. For `map` and `multimap` it is equal to `pair<const Key, T>`.

`iterator` of an associative container is of the bidirectional iterator category. For associative containers where the value type is the same as the key type, both `iterator` and `const_iterator` are constant iterators. It is unspecified whether or not `iterator` and `const_iterator` are the same type.

NOTE 2 `iterator` and `const_iterator` have identical semantics in this case, and `iterator` is convertible to `const_iterator`. Users can avoid violating the one-definition rule by always using `const_iterator` in their function parameter lists.

In this subclause,

- `X` denotes an associative container class,
- `a` denotes a value of type `X`,
- `a2` denotes a value of a type with nodes compatible with type `X` (Table 83),
- `b` denotes a value or type `X` or `const X`,
- `u` denotes the name of a variable being declared,
- `a_uniq` denotes a value of type `X` when `X` supports unique keys,
- `a_eq` denotes a value of type `X` when `X` supports multiple keys,
- `a_tran` denotes a value of type `X` or `const X` when the *qualified-id* `X::key_compare::is_transparent` is valid and denotes a type (13.10.3),
- `i` and `j` meet the *Cpp17InputIterator* requirements and refer to elements implicitly convertible to `value_type`,
- `[i, j)` denotes a valid range,
- `rg` denotes a value of a type `R` that models *container-compatible-range*<value_type>>,
- `p` denotes a valid constant iterator to `a`,
- `q` denotes a valid dereferenceable constant iterator to `a`,
- `r` denotes a valid dereferenceable iterator to `a`,
- `[q1, q2)` denotes a valid range of constant iterators in `a`,
- `il` designates an object of type `initializer_list<value_type>`,
- `t` denotes a value of type `X::value_type`,
- `k` denotes a value of type `X::key_type`, and
- `c` denotes a value of type `X::key_compare` or `const X::key_compare`;
- `k1` is a value such that `a` is partitioned (27.8) with respect to `c(x, k1)`, with `x` the key value of `e` and `e` in `a`;
- `ku` is a value such that `a` is partitioned with respect to `!c(ku, x)`, with `x` the key value of `e` and `e` in `a`;
- `ke` is a value such that `a` is partitioned with respect to `c(x, ke)` and `!c(ke, x)`, with `c(x, ke)` implying `!c(ke, x)` and with `x` the key value of `e` and `e` in `a`;
- `kx` is a value such that
 - `a` is partitioned with respect to `c(x, kx)` and `!c(kx, x)`, with `c(x, kx)` implying `!c(kx, x)` and with `x` the key value of `e` and `e` in `a`, and
 - `kx` is not convertible to either `iterator` or `const_iterator`; and
- `A` denotes the storage allocator used by `X`, if any, or `allocator<X::value_type>` otherwise,

- `m` denotes an allocator of a type convertible to `A`, and `nh` denotes a non-const rvalue of type `X::node_type`.

A type `X` meets the *associative container* requirements if `X` meets all the requirements of an allocator-aware container (24.2.2.2) and the following types, statements, and expressions are well-formed and have the specified semantics, except that for `map` and `multimap`, the requirements placed on `value_type` in 24.2.2.5 apply instead to `key_type` and `mapped_type`.

NOTE 3 For example, in some cases `key_type` and `mapped_type` need to be *Cpp17CopyAssignable* even though the associated `value_type`, `pair<const key_type, mapped_type>`, is not *Cpp17CopyAssignable*.

`typename X::key_type`

Result: Key.

`typename X::mapped_type`

Result: T.

Remarks: For `map` and `multimap` only.

`typename X::value_type`

Result: Key for `set` and `multiset` only; `pair<const Key, T>` for `map` and `multimap` only.

Preconditions: `X::value_type` is *Cpp17Erasable* from `X`.

`typename X::key_compare`

Result: Compare.

Preconditions: `key_compare` is *Cpp17CopyConstructible*.

`typename X::value_compare`

Result: A binary predicate type. It is the same as `key_compare` for `set` and `multiset`; is an ordering relation on pairs induced by the first component (i.e., Key) for `map` and `multimap`.

`typename X::node_type`

Result: A specialization of the *node-handle* class template (24.2.5), such that the public nested types are the same types as the corresponding types in `X`.

`X(c)`

Effects: Constructs an empty container. Uses a copy of `c` as a comparison object.

Complexity: Constant.

`X u = X();`

`X u;`

Preconditions: `key_compare` meets the *Cpp17DefaultConstructible* requirements.

Effects: Constructs an empty container. Uses `Compare()` as a comparison object.

Complexity: Constant.

`X(i, j, c)`

Preconditions: `value_type` is *Cpp17EraseConstructible* into `X` from `*i`.

Effects: Constructs an empty container and inserts elements from the range `[i, j)` into it; uses `c` as a comparison object.

Complexity: $N \log N$ in general, where N has the value `distance(i, j)`; linear if `[i, j)` is sorted with respect to `value_comp()`.

`X(i, j)`

Preconditions: `key_compare` meets the *Cpp17DefaultConstructible* requirements. `value_type` is *Cpp17EraseConstructible* into `X` from `*i`.

Effects: Constructs an empty container and inserts elements from the range `[i, j)` into it; uses `Compare()` as a comparison object.

Complexity: $N \log N$ in general, where N has the value `distance(i, j)`; linear if $[i, j)$ is sorted with respect to `value_comp()`.

`X(from_range, rg, c)`

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`.

Effects: Constructs an empty container and inserts each element from `rg` into it. Uses `c` as the comparison object.

Complexity: $N \log N$ in general, where N has the value `ranges::distance(rg)`; linear if `rg` is sorted with respect to `value_comp()`.

`X(from_range, rg)`

Preconditions: `key_compare` meets the *Cpp17DefaultConstructible* requirements. `value_type` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`.

Effects: Constructs an empty container and inserts each element from `rg` into it. Uses `Compare()` as the comparison object.

Complexity: Same as `X(from_range, rg, c)`.

`X(il, c)`

Effects: Equivalent to `X(il.begin(), il.end(), c)`.

`X(il)`

Effects: Equivalent to `X(il.begin(), il.end())`.

`a = il`

Result: `X&`

Preconditions: `value_type` is *Cpp17CopyInsertable* into `X` and *Cpp17CopyAssignable*.

Effects: Assigns the range $[il.begin(), il.end())$ into `a`. All existing elements of `a` are either assigned to or destroyed.

Complexity: $N \log N$ in general, where N has the value `il.size() + a.size()`; linear if $[il.begin(), il.end())$ is sorted with respect to `value_comp()`.

`b.key_comp()`

Result: `X::key_compare`

Returns: The comparison object out of which `b` was constructed.

Complexity: Constant.

`b.value_comp()`

Result: `X::value_compare`

Returns: An object of `value_compare` constructed out of the comparison object.

Complexity: Constant.

`a_uniq.emplace(args)`

Result: `pair<iterator, bool>`

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into `X` from `args`.

Effects: Inserts a `value_type` object `t` constructed with `std::forward<Args>(args)...` if and only if there is no element in the container with key equivalent to the key of `t`.

Returns: The `bool` component of the returned pair is `true` if and only if the insertion takes place, and the iterator component of the pair points to the element with key equivalent to the key of `t`.

Complexity: Logarithmic.

`a_eq.emplace(args)`

Result: `iterator`

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into `X` from `args`.

Effects: Inserts a `value_type` object `t` constructed with `std::forward<Args>(args)...`. If a range containing elements equivalent to `t` exists in `a_eq`, `t` is inserted at the end of that range.

Returns: An iterator pointing to the newly inserted element.

Complexity: Logarithmic.

`a.emplace_hint(p, args)`

Result: `iterator`

Effects: Equivalent to `a.emplace(std::forward<Args>(args)...)...`, except that the element is inserted as close as possible to the position just prior to `p`.

Returns: An iterator pointing to the element with the key equivalent to the newly inserted element.

Complexity: Logarithmic in general, but amortized constant if the element is inserted right before `p`.

`a_uniq.insert(t)`

Result: `pair<iterator, bool>`

Preconditions: If `t` is a non-const rvalue, `value_type` is *Cpp17MoveInsertable* into `X`; otherwise, `value_type` is *Cpp17CopyInsertable* into `X`.

Effects: Inserts `t` if and only if there is no element in the container with key equivalent to the key of `t`.

Returns: The `bool` component of the returned pair is `true` if and only if the insertion takes place, and the `iterator` component of the pair points to the element with key equivalent to the key of `t`.

Complexity: Logarithmic.

`a_eq.insert(t)`

Result: `iterator`

Preconditions: If `t` is a non-const rvalue, `value_type` is *Cpp17MoveInsertable* into `X`; otherwise, `value_type` is *Cpp17CopyInsertable* into `X`.

Effects: Inserts `t` and returns the iterator pointing to the newly inserted element. If a range containing elements equivalent to `t` exists in `a_eq`, `t` is inserted at the end of that range.

Complexity: Logarithmic.

`a.insert(p, t)`

Result: `iterator`

Preconditions: If `t` is a non-const rvalue, `value_type` is *Cpp17MoveInsertable* into `X`; otherwise, `value_type` is *Cpp17CopyInsertable* into `X`.

Effects: Inserts `t` if and only if there is no element with key equivalent to the key of `t` in containers with unique keys; always inserts `t` in containers with equivalent keys. `t` is inserted as close as possible to the position just prior to `p`.

Returns: An iterator pointing to the element with key equivalent to the key of `t`.

Complexity: Logarithmic in general, but amortized constant if `t` is inserted right before `p`.

`a.insert(i, j)`

Result: `void`

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into `X` from `*i`. Neither `i` nor `j` are iterators into `a`.

Effects: Inserts each element from the range `[i, j)` if and only if there is no element with key equivalent to the key of that element in containers with unique keys; always inserts that element in containers with equivalent keys.

Complexity: $N \log(a.size() + N)$, where N has the value `distance(i, j)`.

`a.insert_range(rg)`

Result: `void`

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into *X* from `*ranges::begin(rg)`. `rg` and `a` do not overlap.

Effects: Inserts each element from `rg` if and only if there is no element with key equivalent to the key of that element in containers with unique keys; always inserts that element in containers with equivalent keys.

Complexity: $N \log(a.size() + N)$, where N has the value `ranges::distance(rg)`.

`a.insert(il)`

Effects: Equivalent to `a.insert(il.begin(), il.end())`.

`a_uniq.insert(nh)`

Result: `insert_return_type`

Preconditions: `nh` is empty or `a_uniq.get_allocator() == nh.get_allocator()` is true.

Effects: If `nh` is empty, has no effect. Otherwise, inserts the element owned by `nh` if and only if there is no element in the container with a key equivalent to `nh.key()`.

Returns: If `nh` is empty, `inserted` is false, `position` is `end()`, and `node` is empty. Otherwise if the insertion took place, `inserted` is true, `position` points to the inserted element, and `node` is empty; if the insertion failed, `inserted` is false, `node` has the previous value of `nh`, and `position` points to an element with a key equivalent to `nh.key()`.

Complexity: Logarithmic.

`a_eq.insert(nh)`

Result: `iterator`

Preconditions: `nh` is empty or `a_eq.get_allocator() == nh.get_allocator()` is true.

Effects: If `nh` is empty, has no effect and returns `a_eq.end()`. Otherwise, inserts the element owned by `nh` and returns an iterator pointing to the newly inserted element. If a range containing elements with keys equivalent to `nh.key()` exists in `a_eq`, the element is inserted at the end of that range.

Postconditions: `nh` is empty.

Complexity: Logarithmic.

`a.insert(p, nh)`

Result: `iterator`

Preconditions: `nh` is empty or `a.get_allocator() == nh.get_allocator()` is true.

Effects: If `nh` is empty, has no effect and returns `a.end()`. Otherwise, inserts the element owned by `nh` if and only if there is no element with key equivalent to `nh.key()` in containers with unique keys; always inserts the element owned by `nh` in containers with equivalent keys. The element is inserted as close as possible to the position just prior to `p`.

Postconditions: `nh` is empty if insertion succeeds, unchanged if insertion fails.

Returns: An iterator pointing to the element with key equivalent to `nh.key()`.

Complexity: Logarithmic in general, but amortized constant if the element is inserted right before `p`.

`a.extract(k)`

Result: `node_type`

Effects: Removes the first element in the container with key equivalent to `k`.

Returns: A `node_type` owning the element if found, otherwise an empty `node_type`.

Complexity: $\log(a.size())$

`a_tran.extract(kx)`

Result: `node_type`

Effects: Removes the first element in the container with key `r` such that `!c(r, kx) && !c(kx, r)` is true.

Returns: A `node_type` owning the element if found, otherwise an empty `node_type`.

Complexity: $\log(a\_tran.size())$

a.extract(q)

Result: `node_type`

Effects: Removes the element pointed to by `q`.

Returns: A `node_type` owning that element.

Complexity: Amortized constant.

a.merge(a2)

Result: `void`

Preconditions: `a.get_allocator() == a2.get_allocator()`.

Effects: Attempts to extract each element in `a2` and insert it into `a` using the comparison object of `a`. In containers with unique keys, if there is an element in `a` with key equivalent to the key of an element from `a2`, then that element is not extracted from `a2`.

Postconditions: Pointers and references to the transferred elements of `a2` refer to those same elements but as members of `a`. Iterators referring to the transferred elements will continue to refer to their elements, but they now behave as iterators into `a`, not into `a2`.

Throws: Nothing unless the comparison object throws.

Complexity: $N \log(a.size() + N)$, where N has the value `a2.size()`.

a.erase(k)

Result: `size_type`

Effects: Erases all elements in the container with key equivalent to `k`.

Returns: The number of erased elements.

Complexity: $\log(a.size()) + a.count(k)$

a_tran.erase(kx)

Result: `size_type`

Effects: Erases all elements in the container with key `r` such that `!c(r, kx) && !c(kx, r)` is true.

Returns: The number of erased elements.

Complexity: $\log(a\_tran.size()) + a\_tran.count(kx)$

a.erase(q)

Result: `iterator`

Effects: Erases the element pointed to by `q`.

Returns: An iterator pointing to the element immediately following `q` prior to the element being erased. If no such element exists, returns `a.end()`.

Complexity: Amortized constant.

a.erase(r)

Result: `iterator`

Effects: Erases the element pointed to by `r`.

Returns: An iterator pointing to the element immediately following `r` prior to the element being erased. If no such element exists, returns `a.end()`.

Complexity: Amortized constant.

a.erase(q1, q2)

Result: `iterator`

Effects: Erases all the elements in the range `[q1, q2)`.

Returns: An iterator pointing to the element pointed to by `q2` prior to any elements being erased. If no such element exists, `a.end()` is returned.

Complexity: $\log(a.size()) + N$, where N has the value `distance(q1, q2)`.

`a.clear()`

Effects: Equivalent to `a.erase(a.begin(), a.end())`.

Postconditions: `a.empty()` is true.

Complexity: Linear in `a.size()`.

`b.find(k)`

Result: `iterator`; `const_iterator` for constant `b`.

Returns: An iterator pointing to an element with the key equivalent to `k`, or `b.end()` if such an element is not found.

Complexity: Logarithmic.

`a_tran.find(ke)`

Result: `iterator`; `const_iterator` for constant `a_tran`.

Returns: An iterator pointing to an element with key `r` such that `!c(r, ke) && !c(ke, r)` is true, or `a_tran.end()` if such an element is not found.

Complexity: Logarithmic.

`b.count(k)`

Result: `size_type`

Returns: The number of elements with key equivalent to `k`.

Complexity: $\log(b.size()) + b.count(k)$

`a_tran.count(ke)`

Result: `size_type`

Returns: The number of elements with key `r` such that `!c(r, ke) && !c(ke, r)`.

Complexity: $\log(a\_tran.size()) + a\_tran.count(ke)$

`b.contains(k)`

Result: `bool`

Effects: Equivalent to: `return b.find(k) != b.end();`

`a_tran.contains(ke)`

Result: `bool`

Effects: Equivalent to: `return a_tran.find(ke) != a_tran.end();`

`b.lower_bound(k)`

Result: `iterator`; `const_iterator` for constant `b`.

Returns: An iterator pointing to the first element with key not less than `k`, or `b.end()` if such an element is not found.

Complexity: Logarithmic.

`a_tran.lower_bound(kl)`

Result: `iterator`; `const_iterator` for constant `a_tran`.

Returns: An iterator pointing to the first element with key `r` such that `!c(r, kl)`, or `a_tran.end()` if such an element is not found.

Complexity: Logarithmic.

b.upper_bound(k)

Result: `iterator`; `const_iterator` for constant `b`.

Returns: An iterator pointing to the first element with key greater than `k`, or `b.end()` if such an element is not found.

Complexity: Logarithmic.

a_tran.upper_bound(ku)

Result: `iterator`; `const_iterator` for constant `a_tran`.

Returns: An iterator pointing to the first element with key `r` such that `c(ku, r)`, or `a_tran.end()` if such an element is not found.

Complexity: Logarithmic.

b.equal_range(k)

Result: `pair<iterator, iterator>`; `pair<const_iterator, const_iterator>` for constant `b`.

Effects: Equivalent to: `return make_pair(b.lower_bound(k), b.upper_bound(k));`

Complexity: Logarithmic.

a_tran.equal_range(ke)

Result: `pair<iterator, iterator>`; `pair<const_iterator, const_iterator>` for constant `a_tran`.

Effects: Equivalent to: `return make_pair(a_tran.lower_bound(ke), a_tran.upper_bound(ke));`

Complexity: Logarithmic.

The `insert`, `insert_range`, and `emplace` members shall not affect the validity of iterators and references to the container, and the `erase` members shall invalidate only iterators and references to the erased elements.

The `extract` members invalidate only iterators to the removed element; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a `node_type` is undefined behavior. References and pointers to an element obtained while it is owned by a `node_type` are invalidated if the element is successfully inserted.

The fundamental property of iterators of associative containers is that they iterate through the containers in the non-descending order of keys where non-descending is defined by the comparison that was used to construct them. For any two dereferenceable iterators `i` and `j` such that distance from `i` to `j` is positive, the following condition holds:

```
value_comp(*j, *i) == false
```

For associative containers with unique keys the stronger condition holds:

```
value_comp(*i, *j) != false
```

When an associative container is constructed by passing a comparison object the container shall not store a pointer or reference to the passed object, even if that object is passed by reference. When an associative container is copied, through either a copy constructor or an assignment operator, the target container shall then use the comparison object from the container being copied, as if that comparison object had been passed to the target container in its constructor.

The member function templates `find`, `count`, `contains`, `lower_bound`, `upper_bound`, `equal_range`, `erase`, and `extract` shall not participate in overload resolution unless the *qualified-id* `Compare::is_transparent` is valid and denotes a type (13.10.3). Additionally, the member function templates `extract` and `erase` shall not participate in overload resolution if `is_convertible_v<K&&, iterator> || is_convertible_v<K&&, const_iterator>` is `true`, where `K` is the type substituted as the first template argument.

A deduction guide for an associative container shall not participate in overload resolution if any of the following are true:

- It has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter.
- It has an `Allocator` template parameter and a type that does not qualify as an allocator is deduced for that parameter.

- It has a `Compare` template parameter and a type that qualifies as an allocator is deduced for that parameter.

24.2.7.2 Exception safety guarantees [associative.reqmts.except]

For associative containers, no `clear()` function throws an exception. `erase(k)` does not throw an exception unless that exception is thrown by the container's `Compare` object (if any).

For associative containers, if an exception is thrown by any operation from within an `insert` or `emplace` function inserting a single element, the insertion has no effect.

For associative containers, no `swap` function throws an exception unless that exception is thrown by the swap of the container's `Compare` object (if any).

24.2.8 Unordered associative containers [unord.req]

24.2.8.1 General [unord.req.general]

Unordered associative containers provide an ability for fast retrieval of data based on keys. The worst-case complexity for most operations is linear, but the average case is much faster. The library provides four unordered associative containers: `unordered_set`, `unordered_map`, `unordered_multiset`, and `unordered_multimap`.

Unordered associative containers conform to the requirements for Containers (24.2), except that the expressions `a == b` and `a != b` have different semantics than for the other container types.

Each unordered associative container is parameterized by `Key`, by a function object type `Hash` that meets the *Cpp17Hash* requirements (16.4.4.5) and acts as a hash function for argument values of type `Key`, and by a binary predicate `Pred` that induces an equivalence relation on values of type `Key`. Additionally, `unordered_map` and `unordered_multimap` associate an arbitrary *mapped type* `T` with the `Key`.

The container's object of type `Hash` — denoted by `hash` — is called the *hash function* of the container. The container's object of type `Pred` — denoted by `pred` — is called the *key equality predicate* of the container.

Two values `k1` and `k2` are considered equivalent if the container's key equality predicate `pred(k1, k2)` is valid and returns `true` when passed those values. If `k1` and `k2` are equivalent, the container's hash function shall return the same value for both.

NOTE 1 Thus, when an unordered associative container is instantiated with a non-default `Pred` parameter it usually needs a non-default `Hash` parameter as well.

For any two keys `k1` and `k2` in the same container, calling `pred(k1, k2)` shall always return the same value. For any key `k` in a container, calling `hash(k)` shall always return the same value.

An unordered associative container supports *unique keys* if it may contain at most one element for each key. Otherwise, it supports *equivalent keys*. `unordered_set` and `unordered_map` support unique keys. `unordered_multiset` and `unordered_multimap` support equivalent keys. In containers that support equivalent keys, elements with equivalent keys are adjacent to each other in the iteration order of the container. Thus, although the absolute order of elements in an unordered container is not specified, its elements are grouped into *equivalent-key groups* such that all elements of each group have equivalent keys. Mutating operations on unordered containers shall preserve the relative order of elements within each equivalent-key group unless otherwise specified.

For `unordered_set` and `unordered_multiset` the value type is the same as the key type. For `unordered_map` and `unordered_multimap` it is `pair<const Key, T>`.

For unordered containers where the value type is the same as the key type, both `iterator` and `const_iterator` are constant iterators. It is unspecified whether or not `iterator` and `const_iterator` are the same type.

NOTE 2 `iterator` and `const_iterator` have identical semantics in this case, and `iterator` is convertible to `const_iterator`. Users can avoid violating the one-definition rule by always using `const_iterator` in their function parameter lists.

The elements of an unordered associative container are organized into *buckets*. Keys with the same hash code appear in the same bucket. The number of buckets is automatically increased as elements are added to an unordered associative container, so that the average number of elements per bucket is kept below a bound. Rehashing invalidates iterators, changes ordering between elements, and changes which buckets elements appear in, but does not invalidate pointers or references to elements. For `unordered_multiset` and `unordered_multimap`, rehashing preserves the relative ordering of equivalent elements.

In this subclause,

- `X` denotes an unordered associative container class,
- `a` denotes a value of type `X`,
- `a2` denotes a value of a type with nodes compatible with type `X` (Table 83),
- `b` denotes a value of type `X` or `const X`,
- `a_uniq` denotes a value of type `X` when `X` supports unique keys,
- `a_eq` denotes a value of type `X` when `X` supports equivalent keys,
- `a_tran` denotes a value of type `X` or `const X` when the *qualified-ids* `X::key_equal::is_transparent` and `X::hasher::is_transparent` are both valid and denote types (13.10.3),
- `i` and `j` denote input iterators that refer to `value_type`,
- `[i, j)` denotes a valid range,
- `rg` denotes a value of a type `R` that models *container-compatible-range*<`value_type`>,
- `p` and `q2` denote valid constant iterators to `a`,
- `q` and `q1` denote valid dereferenceable constant iterators to `a`,
- `r` denotes a valid dereferenceable iterator to `a`,
- `[q1, q2)` denotes a valid range in `a`,
- `il` denotes a value of type `initializer_list<value_type>`,
- `t` denotes a value of type `X::value_type`,
- `k` denotes a value of type `key_type`,
- `hf` denotes a value of type `hasher` or `const hasher`,
- `eq` denotes a value of type `key_equal` or `const key_equal`,
- `ke` is a value such that
 - `eq(r1, ke) == eq(ke, r1)`,
 - `hf(r1) == hf(ke)` if `eq(r1, ke)` is `true`, and
 - if any two of `eq(r1, ke)`, `eq(r2, ke)`, and `eq(r1, r2)` are `true`, then all three are `true`,
 where `r1` and `r2` are keys of elements in `a_tran`,
- `kx` is a value such that
 - `eq(r1, kx) == eq(kx, r1)`,
 - `hf(r1) == hf(kx)` if `eq(r1, kx)` is `true`,
 - if any two of `eq(r1, kx)`, `eq(r2, kx)`, and `eq(r1, r2)` are `true`, then all three are `true`, and
 - `kx` is not convertible to either `iterator` or `const_iterator`,
 where `r1` and `r2` are keys of elements in `a_tran`,
- `n` denotes a value of type `size_type`,
- `z` denotes a value of type `float`, and
- `nh` denotes an rvalue of type `X::node_type`.

A type `X` meets the *unordered associative container* requirements if `X` meets all the requirements of an allocator-aware container (24.2.2.2) and the following types, statements, and expressions are well-formed and have the specified semantics, except that for `unordered_map` and `unordered_multimap`, the requirements placed on `value_type` in 24.2.2.5 apply instead to `key_type` and `mapped_type`.

NOTE 3 For example, `key_type` and `mapped_type` sometimes need to be *Cpp17CopyAssignable* even though the associated `value_type`, `pair<const key_type, mapped_type>`, is not *Cpp17CopyAssignable*.

typename `X::key_type`

Result: Key.

typename X::mapped_type

Result: T.

Remarks: For unordered_map and unordered_multimap only.

typename X::value_type

Result: Key for unordered_set and unordered_multiset only; pair<const Key, T> for unordered_map and unordered_multimap only.

Preconditions: value_type is Cpp17Erasable from X.

typename X::hasher

Result: Hash.

Preconditions: Hash is a unary function object type such that the expression hf(k) has type size_t.

typename X::key_equal

Result: Pred.

Preconditions: Pred meets the Cpp17CopyConstructible requirements. Pred is a binary predicate that takes two arguments of type Key. Pred is an equivalence relation.

typename X::local_iterator

Result: An iterator type whose category, value type, difference type, and pointer and reference types are the same as X::iterator's.

NOTE 4 A local_iterator object is usable for iteration through a single bucket, but not for iteration across buckets.

typename X::const_local_iterator

Result: An iterator type whose category, value type, difference type, and pointer and reference types are the same as X::const_iterator's.

NOTE 5 A const_local_iterator object is usable for iteration through a single bucket, but not for iteration across buckets.

typename X::node_type

Result: A specialization of a *node-handle* class template (24.2.5), such that the public nested types are the same types as the corresponding types in X.

X(n, hf, eq)

Effects: Constructs an empty container with at least n buckets, using hf as the hash function and eq as the key equality predicate.

Complexity: $\mathcal{O}(n)$

X(n, hf)

Preconditions: key_equal meets the Cpp17DefaultConstructible requirements.

Effects: Constructs an empty container with at least n buckets, using hf as the hash function and key_equal() as the key equality predicate.

Complexity: $\mathcal{O}(n)$

X(n)

Preconditions: hasher and key_equal meet the Cpp17DefaultConstructible requirements.

Effects: Constructs an empty container with at least n buckets, using hasher() as the hash function and key_equal() as the key equality predicate.

Complexity: $\mathcal{O}(n)$

X a = X();

X a;

Preconditions: hasher and key_equal meet the Cpp17DefaultConstructible requirements.

Effects: Constructs an empty container with an unspecified number of buckets, using `hasher()` as the hash function and `key_equal()` as the key equality predicate.

Complexity: Constant.

`X(i, j, n, hf, eq)`

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into `X` from `*i`.

Effects: Constructs an empty container with at least `n` buckets, using `hf` as the hash function and `eq` as the key equality predicate, and inserts elements from `[i, j)` into it.

Complexity: Average case $\mathcal{O}(N)$ (N is `distance(i, j)`), worst case $\mathcal{O}(N^2)$.

`X(i, j, n, hf)`

Preconditions: `key_equal` meets the *Cpp17DefaultConstructible* requirements. `value_type` is *Cpp17EmplaceConstructible* into `X` from `*i`.

Effects: Constructs an empty container with at least `n` buckets, using `hf` as the hash function and `key_equal()` as the key equality predicate, and inserts elements from `[i, j)` into it.

Complexity: Average case $\mathcal{O}(N)$ (N is `distance(i, j)`), worst case $\mathcal{O}(N^2)$.

`X(i, j, n)`

Preconditions: `hasher` and `key_equal` meet the *Cpp17DefaultConstructible* requirements. `value_type` is *Cpp17EmplaceConstructible* into `X` from `*i`.

Effects: Constructs an empty container with at least `n` buckets, using `hasher()` as the hash function and `key_equal()` as the key equality predicate, and inserts elements from `[i, j)` into it.

Complexity: Average case $\mathcal{O}(N)$ (N is `distance(i, j)`), worst case $\mathcal{O}(N^2)$.

`X(i, j)`

Preconditions: `hasher` and `key_equal` meet the *Cpp17DefaultConstructible* requirements. `value_type` is *Cpp17EmplaceConstructible* into `X` from `*i`.

Effects: Constructs an empty container with an unspecified number of buckets, using `hasher()` as the hash function and `key_equal()` as the key equality predicate, and inserts elements from `[i, j)` into it.

Complexity: Average case $\mathcal{O}(N)$ (N is `distance(i, j)`), worst case $\mathcal{O}(N^2)$.

`X(from_range, rg, n, hf, eq)`

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`.

Effects: Constructs an empty container with at least `n` buckets, using `hf` as the hash function and `eq` as the key equality predicate, and inserts elements from `rg` into it.

Complexity: Average case $\mathcal{O}(N)$ (N is `ranges::distance(rg)`), worst case $\mathcal{O}(N^2)$.

`X(from_range, rg, n, hf)`

Preconditions: `key_equal` meets the *Cpp17DefaultConstructible* requirements. `value_type` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`.

Effects: Constructs an empty container with at least `n` buckets, using `hf` as the hash function and `key_equal()` as the key equality predicate, and inserts elements from `rg` into it.

Complexity: Average case $\mathcal{O}(N)$ (N is `ranges::distance(rg)`), worst case $\mathcal{O}(N^2)$.

`X(from_range, rg, n)`

Preconditions: `hasher` and `key_equal` meet the *Cpp17DefaultConstructible* requirements. `value_type` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`.

Effects: Constructs an empty container with at least `n` buckets, using `hasher()` as the hash function and `key_equal()` as the key equality predicate, and inserts elements from `rg` into it.

Complexity: Average case $\mathcal{O}(N)$ (N is `ranges::distance(rg)`), worst case $\mathcal{O}(N^2)$.

X(from_range, rg)

Preconditions: **hasher** and **key_equal** meet the *Cpp17DefaultConstructible* requirements. **value_type** is *Cpp17EmplaceConstructible* into **X** from ***ranges::begin(rg)**.

Effects: Constructs an empty container with an unspecified number of buckets, using **hasher()** as the hash function and **key_equal()** as the key equality predicate, and inserts elements from **rg** into it.

Complexity: Average case $\mathcal{O}(N)$ (N is **ranges::distance(rg)**), worst case $\mathcal{O}(N^2)$.

X(il)

Effects: Equivalent to **X(il.begin(), il.end())**.

X(il, n)

Effects: Equivalent to **X(il.begin(), il.end(), n)**.

X(il, n, hf)

Effects: Equivalent to **X(il.begin(), il.end(), n, hf)**.

X(il, n, hf, eq)

Effects: Equivalent to **X(il.begin(), il.end(), n, hf, eq)**.

X(b)

Effects: In addition to the container requirements (24.2.2.2), copies the hash function, predicate, and maximum load factor.

Complexity: Average case linear in **b.size()**, worst case quadratic.

a = b

Result: **X&**

Effects: In addition to the container requirements, copies the hash function, predicate, and maximum load factor.

Complexity: Average case linear in **b.size()**, worst case quadratic.

a = il

Result: **X&**

Preconditions: **value_type** is *Cpp17CopyInsertable* into **X** and *Cpp17CopyAssignable*.

Effects: Assigns the range [**il.begin()**, **il.end()**) into **a**. All existing elements of **a** are either assigned to or destroyed.

Complexity: Average case linear in **il.size()**, worst case quadratic.

b.hash_function()

Result: **hasher**

Returns: **b**'s hash function.

Complexity: Constant.

b.key_eq()

Result: **key_equal**

Returns: **b**'s key equality predicate.

Complexity: Constant.

a_uniq.emplace(args)

Result: **pair<iterator, bool>**

Preconditions: **value_type** is *Cpp17EmplaceConstructible* into **X** from **args**.

Effects: Inserts a **value_type** object **t** constructed with **std::forward<Args>(args)...** if and only if there is no element in the container with key equivalent to the key of **t**.

Returns: The `bool` component of the returned pair is `true` if and only if the insertion takes place, and the iterator component of the pair points to the element with key equivalent to the key of `t`.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(\text{a\_uniq.size}())$.

`a_eq.emplace(args)`

Result: iterator

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into `X` from `args`.

Effects: Inserts a `value_type` object `t` constructed with `std::forward<Args>(args)...`

Returns: An iterator pointing to the newly inserted element.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(\text{a_eq.size}())$.

`a.emplace_hint(p, args)`

Result: iterator

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into `X` from `args`.

Effects: Equivalent to `a.emplace(std::forward<Args>(args)...)...`

Returns: An iterator pointing to the element with the key equivalent to the newly inserted element. The `const_iterator` `p` is a hint pointing to where the search should start. Implementations are permitted to ignore the hint.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(\text{a.size}())$.

`a_uniq.insert(t)`

Result: `pair<iterator, bool>`

Preconditions: If `t` is a non-const rvalue, `value_type` is *Cpp17MoveInsertable* into `X`; otherwise, `value_type` is *Cpp17CopyInsertable* into `X`.

Effects: Inserts `t` if and only if there is no element in the container with key equivalent to the key of `t`.

Returns: The `bool` component of the returned pair indicates whether the insertion takes place, and the `iterator` component points to the element with key equivalent to the key of `t`.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(\text{a\_uniq.size}())$.

`a_eq.insert(t)`

Result: iterator

Preconditions: If `t` is a non-const rvalue, `value_type` is *Cpp17MoveInsertable* into `X`; otherwise, `value_type` is *Cpp17CopyInsertable* into `X`.

Effects: Inserts `t`.

Returns: An iterator pointing to the newly inserted element.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(\text{a_eq.size}())$.

`a.insert(p, t)`

Result: iterator

Preconditions: If `t` is a non-const rvalue, `value_type` is *Cpp17MoveInsertable* into `X`; otherwise, `value_type` is *Cpp17CopyInsertable* into `X`.

Effects: Equivalent to `a.insert(t)`. The iterator `p` is a hint pointing to where the search should start. Implementations are permitted to ignore the hint.

Returns: An iterator pointing to the element with the key equivalent to that of `t`.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(\text{a.size}())$.

`a.insert(i, j)`

Result: void

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into `X` from `*i`. Neither `i` nor `j` are iterators into `a`.

Effects: Equivalent to `a.insert(t)` for each element in `[i,j)`.

Complexity: Average case $\mathcal{O}(N)$, where N is `distance(i, j)`, worst case $\mathcal{O}(N(a.size() + 1))$.

`a.insert_range(rg)`

Result: `void`

Preconditions: `value_type` is `Cpp17EmplaceConstructible` into `X` from `*ranges::begin(rg)`. `rg` and `a` do not overlap.

Effects: Equivalent to `a.insert(t)` for each element `t` in `rg`.

Complexity: Average case $\mathcal{O}(N)$, where N is `ranges::distance(rg)`, worst case $\mathcal{O}(N(a.size() + 1))$.

`a.insert(il)`

Effects: Equivalent to `a.insert(il.begin(), il.end())`.

`a_uniq.insert(nh)`

Result: `insert_return_type`

Preconditions: `nh` is empty or `a_uniq.get_allocator() == nh.get_allocator()` is true.

Effects: If `nh` is empty, has no effect. Otherwise, inserts the element owned by `nh` if and only if there is no element in the container with a key equivalent to `nh.key()`.

Postconditions: If `nh` is empty, `inserted` is false, `position` is `end()`, and `node` is empty. Otherwise if the insertion took place, `inserted` is true, `position` points to the inserted element, and `node` is empty; if the insertion failed, `inserted` is false, `node` has the previous value of `nh`, and `position` points to an element with a key equivalent to `nh.key()`.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(a\_uniq.size())$.

`a_eq.insert(nh)`

Result: `iterator`

Preconditions: `nh` is empty or `a_eq.get_allocator() == nh.get_allocator()` is true.

Effects: If `nh` is empty, has no effect and returns `a_eq.end()`. Otherwise, inserts the element owned by `nh` and returns an iterator pointing to the newly inserted element.

Postconditions: `nh` is empty.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(a\_eq.size())$.

`a.insert(q, nh)`

Result: `iterator`

Preconditions: `nh` is empty or `a.get_allocator() == nh.get_allocator()` is true.

Effects: If `nh` is empty, has no effect and returns `a.end()`. Otherwise, inserts the element owned by `nh` if and only if there is no element with key equivalent to `nh.key()` in containers with unique keys; always inserts the element owned by `nh` in containers with equivalent keys. The iterator `q` is a hint pointing to where the search should start. Implementations are permitted to ignore the hint.

Postconditions: `nh` is empty if insertion succeeds, unchanged if insertion fails.

Returns: An iterator pointing to the element with key equivalent to `nh.key()`.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(a.size())$.

`a.extract(k)`

Result: `node_type`

Effects: Removes an element in the container with key equivalent to `k`.

Returns: A `node_type` owning the element if found, otherwise an empty `node_type`.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(a.size())$.

`a_tran.extract(kx)`

Result: `node_type`

Effects: Removes an element in the container with key equivalent to `kx`.

Returns: A `node_type` owning the element if found, otherwise an empty `node_type`.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(\text{a\_tran.size}())$.

`a.extract(q)`

Result: `node_type`

Effects: Removes the element pointed to by `q`.

Returns: A `node_type` owning that element.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(\text{a.size}())$.

`a.merge(a2)`

Result: `void`

Preconditions: `a.get_allocator() == a2.get_allocator()`.

Effects: Attempts to extract each element in `a2` and insert it into `a` using the hash function and key equality predicate of `a`. In containers with unique keys, if there is an element in `a` with key equivalent to the key of an element from `a2`, then that element is not extracted from `a2`.

Postconditions: Pointers and references to the transferred elements of `a2` refer to those same elements but as members of `a`. Iterators referring to the transferred elements and all iterators referring to `a` will be invalidated, but iterators to elements remaining in `a2` will remain valid.

Complexity: Average case $\mathcal{O}(N)$, where N is `a2.size()`, worst case $\mathcal{O}(N * \text{a.size}() + N)$.

`a.erase(k)`

Result: `size_type`

Effects: Erases all elements with key equivalent to `k`.

Returns: The number of elements erased.

Complexity: Average case $\mathcal{O}(\text{a.count}(k))$, worst case $\mathcal{O}(\text{a.size}())$.

`a_tran.erase(kx)`

Result: `size_type`

Effects: Erases all elements with key equivalent to `kx`.

Returns: The number of elements erased.

Complexity: Average case $\mathcal{O}(\text{a\_tran.count}(kx))$, worst case $\mathcal{O}(\text{a\_tran.size}())$.

`a.erase(q)`

Result: `iterator`

Effects: Erases the element pointed to by `q`.

Returns: The iterator immediately following `q` prior to the erasure.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(\text{a.size}())$.

`a.erase(r)`

Result: `iterator`

Effects: Erases the element pointed to by `r`.

Returns: The iterator immediately following `r` prior to the erasure.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(\text{a.size}())$.

`a.erase(q1, q2)`

Result: `iterator`

Effects: Erases all elements in the range `[q1, q2)`.

Returns: The iterator immediately following the erased elements prior to the erasure.

Complexity: Average case linear in `distance(q1, q2)`, worst case $\mathcal{O}(\text{a.size}())$.

a.clear()

Result: void

Effects: Erases all elements in the container.

Postconditions: a.empty() is true.

Complexity: Linear in a.size().

b.find(k)

Result: iterator; const_iterator for constant b.

Returns: An iterator pointing to an element with key equivalent to k, or b.end() if no such element exists.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(b.size())$.

a_tran.find(ke)

Result: iterator; const_iterator for constant a_tran.

Returns: An iterator pointing to an element with key equivalent to ke, or a_tran.end() if no such element exists.

Complexity: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(a\_tran.size())$.

b.count(k)

Result: size_type

Returns: The number of elements with key equivalent to k.

Complexity: Average case $\mathcal{O}(b.count(k))$, worst case $\mathcal{O}(b.size())$.

a_tran.count(ke)

Result: size_type

Returns: The number of elements with key equivalent to ke.

Complexity: Average case $\mathcal{O}(a\_tran.count(ke))$, worst case $\mathcal{O}(a\_tran.size())$.

b.contains(k)

Effects: Equivalent to b.find(k) != b.end().

a_tran.contains(ke)

Effects: Equivalent to a_tran.find(ke) != a_tran.end().

b.equal_range(k)

Result: pair<iterator, iterator>; pair<const_iterator, const_iterator> for constant b.

Returns: A range containing all elements with keys equivalent to k. Returns make_pair(b.end(), b.end()) if no such elements exist.

Complexity: Average case $\mathcal{O}(b.count(k))$, worst case $\mathcal{O}(b.size())$.

a_tran.equal_range(ke)

Result: pair<iterator, iterator>; pair<const_iterator, const_iterator> for constant a_tran.

Returns: A range containing all elements with keys equivalent to ke. Returns make_pair(a_tran.end(), a_tran.end()) if no such elements exist.

Complexity: Average case $\mathcal{O}(a\_tran.count(ke))$, worst case $\mathcal{O}(a\_tran.size())$.

b.bucket_count()

Result: size_type

Returns: The number of buckets that b contains.

Complexity: Constant.

b.max_bucket_count()

Result: **size_type**

Returns: An upper bound on the number of buckets that **b** can ever contain.

Complexity: Constant.

b.bucket(k)

Result: **size_type**

Preconditions: **b.bucket_count()** > 0.

Returns: The index of the bucket in which elements with keys equivalent to **k** would be found, if any such element existed. The return value is in the range $[0, \text{b.bucket\_count}())$.

Complexity: Constant.

b.bucket_size(n)

Result: **size_type**

Preconditions: **n** shall be in the range $[0, \text{b.bucket\_count}())$.

Returns: The number of elements in the n^{th} bucket.

Complexity: $\mathcal{O}(\text{b.bucket\_size}(n))$

b.begin(n)

Result: **local_iterator**; **const_local_iterator** for constant **b**.

Preconditions: **n** is in the range $[0, \text{b.bucket\_count}())$.

Returns: An iterator referring to the first element in the bucket. If the bucket is empty, then **b.begin(n) == b.end(n)**.

Complexity: Constant.

b.end(n)

Result: **local_iterator**; **const_local_iterator** for constant **b**.

Preconditions: **n** is in the range $[0, \text{b.bucket\_count}())$.

Returns: An iterator which is the past-the-end value for the bucket.

Complexity: Constant.

b.cbegin(n)

Result: **const_local_iterator**

Preconditions: **n** shall be in the range $[0, \text{b.bucket\_count}())$.

Returns: An iterator referring to the first element in the bucket. If the bucket is empty, then **b.cbegin(n) == b.cend(n)**.

Complexity: Constant.

b.cend(n)

Result: **const_local_iterator**

Preconditions: **n** is in the range $[0, \text{b.bucket\_count}())$.

Returns: An iterator which is the past-the-end value for the bucket.

Complexity: Constant.

b.load_factor()

Result: **float**

Returns: The average number of elements per bucket.

Complexity: Constant.

b.max_load_factor()

Result: float

Returns: A positive number that the container attempts to keep the load factor less than or equal to. The container automatically increases the number of buckets as necessary to keep the load factor below this number.

Complexity: Constant.

a.max_load_factor(z)

Result: void

Preconditions: **z** is positive. May change the container's maximum load factor, using **z** as a hint.

Complexity: Constant.

a.rehash(n)

Result: void

Postconditions: **a.bucket_count()** $\geq$ **a.size()** / **a.max_load_factor()** and **a.bucket_count()** $\geq$ **n**.

Complexity: Average case linear in **a.size()**, worst case quadratic.

a.reserve(n)

Effects: Equivalent to **a.rehash(ceil(n / a.max_load_factor()))**.

Two unordered containers **a** and **b** compare equal if **a.size()** == **b.size()** and, for every equivalent-key group [Ea1,Ea2) obtained from **a.equal_range(Ea1)**, there exists an equivalent-key group [Eb1,Eb2) obtained from **b.equal_range(Ea1)**, such that **is_permutation(Ea1, Ea2, Eb1, Eb2)** returns true. For **unordered_set** and **unordered_map**, the complexity of **operator==** (i.e., the number of calls to the == operator of the **value_type**, to the predicate returned by **key_eq()**, and to the hasher returned by **hash_function()**) is proportional to N in the average case and to N^2 in the worst case, where N is **a.size()**. For **unordered_multiset** and **unordered_multimap**, the complexity of **operator==** is proportional to $\sum E_i^2$ in the average case and to N^2 in the worst case, where N is **a.size()**, and E_i is the size of the i^{th} equivalent-key group in **a**. However, if the respective elements of each corresponding pair of equivalent-key groups Ea_i and Eb_i are arranged in the same order (as is commonly the case, e.g., if **a** and **b** are unmodified copies of the same container), then the average-case complexity for **unordered_multiset** and **unordered_multimap** becomes proportional to N (but worst-case complexity remains $\mathcal{O}(N^2)$, e.g., for a pathologically bad hash function). The behavior of a program that uses **operator==** or **operator!=** on unordered containers is undefined unless the **Pred** function object has the same behavior for both containers and the equality comparison function for **Key** is a refinement²⁰⁸ of the partition into equivalent-key groups produced by **Pred**.

The iterator types **iterator** and **const_iterator** of an unordered associative container are of at least the forward iterator category. For unordered associative containers where the key type and value type are the same, both **iterator** and **const_iterator** are constant iterators.

The **insert**, **insert_range**, and **emplace** members shall not affect the validity of references to container elements, but may invalidate all iterators to the container. The **erase** members shall invalidate only iterators and references to the erased elements, and preserve the relative order of the elements that are not erased.

The **insert**, **insert_range**, and **emplace** members shall not affect the validity of iterators if $(N+n) \leq z * B$, where N is the number of elements in the container prior to the insert operation, n is the number of elements inserted, B is the container's bucket count, and z is the container's maximum load factor.

The **extract** members invalidate only iterators to the removed element, and preserve the relative order of the elements that are not erased; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a **node_type** is undefined behavior. References and pointers to an element obtained while it is owned by a **node_type** are invalidated if the element is successfully inserted.

The member function templates **find**, **count**, **equal_range**, **contains**, **extract**, and **erase** shall not participate in overload resolution unless the *qualified-ids* **Pred::is_transparent** and **Hash::is_transparent** are both valid and denote types (13.10.3). Additionally, the member function templates **extract** and **erase**

208) Equality comparison is a refinement of partitioning if no two objects that compare equal fall into different partitions.

shall not participate in overload resolution if `is_convertible_v<K&&, iterator> || is_convertible_v<K&&, const_iterator>` is `true`, where `K` is the type substituted as the first template argument.

A deduction guide for an unordered associative container shall not participate in overload resolution if any of the following are true:

- It has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter.
- It has an `Allocator` template parameter and a type that does not qualify as an allocator is deduced for that parameter.
- It has a `Hash` template parameter and an integral type or a type that qualifies as an allocator is deduced for that parameter.
- It has a `Pred` template parameter and a type that qualifies as an allocator is deduced for that parameter.

24.2.8.2 Exception safety guarantees

[unord.req.except]

For unordered associative containers, no `clear()` function throws an exception. `erase(k)` does not throw an exception unless that exception is thrown by the container's `Hash` or `Pred` object (if any).

For unordered associative containers, if an exception is thrown by any operation other than the container's hash function from within an `insert` or `emplace` function inserting a single element, the insertion has no effect.

For unordered associative containers, no `swap` function throws an exception unless that exception is thrown by the swap of the container's `Hash` or `Pred` object (if any).

For unordered associative containers, if an exception is thrown from within a `rehash()` function other than by the container's hash function or comparison function, the `rehash()` function has no effect.

24.3 Sequence containers

[sequences]

24.3.1 General

[sequences.general]

The headers `<array>` (24.3.2), `<deque>` (24.3.3), `<forward_list>` (24.3.4), `<list>` (24.3.5), and `<vector>` (24.3.6) define class templates that meet the requirements for sequence containers.

The following exposition-only alias template may appear in deduction guides for sequence containers:

```
template<class InputIterator>
    using iter-value-type = typename iterator_traits<InputIterator>::value_type; // exposition only
```

24.3.2 Header `<array>` synopsis

[array.syn]

```
#include <compare> // see 17.11.1
#include <initializer_list> // see 17.10.2

namespace std {
    // 24.3.7, class template array
    template<class T, size_t N> struct array;

    template<class T, size_t N>
        constexpr bool operator==(const array<T, N>& x, const array<T, N>& y);
    template<class T, size_t N>
        constexpr synth-three-way-result<T>
            operator<=>(const array<T, N>& x, const array<T, N>& y);

    // 24.3.7.4, specialized algorithms
    template<class T, size_t N>
        constexpr void swap(array<T, N>& x, array<T, N>& y) noexcept(noexcept(x.swap(y)));

    // 24.3.7.6, array creation functions
    template<class T, size_t N>
        constexpr array<remove_cv_t<T>, N> to_array(T (&a)[N]);
    template<class T, size_t N>
        constexpr array<remove_cv_t<T>, N> to_array(T (&&a)[N]);
```

```

// 24.3.7.7, tuple interface
template<class T> struct tuple_size;
template<size_t I, class T> struct tuple_element;
template<class T, size_t N>
    struct tuple_size<array<T, N>>;
template<size_t I, class T, size_t N>
    struct tuple_element<I, array<T, N>>;
template<size_t I, class T, size_t N>
    constexpr T& get(array<T, N>&) noexcept;
template<size_t I, class T, size_t N>
    constexpr T&& get(array<T, N>&&) noexcept;
template<size_t I, class T, size_t N>
    constexpr const T& get(const array<T, N>&) noexcept;
template<size_t I, class T, size_t N>
    constexpr const T&& get(const array<T, N>&&) noexcept;
}

```

24.3.3 Header <deque> synopsis

[deque.syn]

```

#include <compare>           // see 17.11.1
#include <initializer_list>   // see 17.10.2

namespace std {
    // 24.3.8, class template deque
    template<class T, class Allocator = allocator<T>> class deque;

    template<class T, class Allocator>
        bool operator==(const deque<T, Allocator>& x, const deque<T, Allocator>& y);
    template<class T, class Allocator>
        synth-three-way-result<T> operator<=(const deque<T, Allocator>& x,
                                              const deque<T, Allocator>& y);

    template<class T, class Allocator>
        void swap(deque<T, Allocator>& x, deque<T, Allocator>& y)
            noexcept(noexcept(x.swap(y)));

    // 24.3.8.5, erasure
    template<class T, class Allocator, class U>
        typename deque<T, Allocator>::size_type
            erase(deque<T, Allocator>& c, const U& value);
    template<class T, class Allocator, class Predicate>
        typename deque<T, Allocator>::size_type
            erase_if(deque<T, Allocator>& c, Predicate pred);

    namespace pmr {
        template<class T>
            using deque = std::deque<T, polymorphic_allocator<T>>;
    }
}

```

24.3.4 Header <forward_list> synopsis

[forward.list.syn]

```

#include <compare>           // see 17.11.1

    struct formatter<T, charT>;
}

```

24.3.7 Class template array

[array]

24.3.7.1 Overview

[array.overview]

The header `<array>` defines a class template for storing fixed-size sequences of objects. An **array** is a contiguous container (24.2.2.2). An instance of `array<T, N>` stores N elements of type T , so that `size() == N` is an invariant.

An **array** is an aggregate (9.4.2) that can be list-initialized with up to N elements whose types are convertible to T .

An **array** meets all of the requirements of a container (24.2.2.2) and of a reversible container (24.2.2.3), except that a default constructed **array** object is not empty if $N > 0$. An **array** meets some of the requirements of a sequence container (24.2.4). Descriptions are provided here only for operations on **array** that are not described in one of these tables and for operations where there is additional semantic information.

`array<T, N>` is a structural type (13.2) if T is a structural type. Two values `a1` and `a2` of type `array<T, N>` are template-argument-equivalent (13.6) if and only if each pair of corresponding elements in `a1` and `a2` are template-argument-equivalent.

The types `iterator` and `const_iterator` meet the constexpr iterator requirements (25.3.1).

```

namespace std {
    template<class T, size_t N>
    struct array {
        // types
        using value_type      = T;
        using pointer         = T*;
        using const_pointer   = const T*;
        using reference       = T&;
        using const_reference = const T&;
        using size_type       = size_t;
        using difference_type = ptrdiff_t;
    };
}

```

```

using iterator          = implementation-defined; // see 24.2
using const_iterator    = implementation-defined; // see 24.2
using reverse_iterator  = std::reverse_iterator<iterator>;
using const_reverse_iterator = std::reverse_iterator<const_iterator>;

// no explicit construct/copy/destroy for aggregate type

constexpr void fill(const T& u);
constexpr void swap(array&) noexcept(is_nothrow_swappable_v<T>);

// iterators
constexpr iterator      begin() noexcept;
constexpr const_iterator begin() const noexcept;
constexpr iterator      end() noexcept;
constexpr const_iterator end() const noexcept;

constexpr reverse_iterator rbegin() noexcept;
constexpr const_reverse_iterator rbegin() const noexcept;
constexpr reverse_iterator rend() noexcept;
constexpr const_reverse_iterator rend() const noexcept;

constexpr const_iterator cbegin() const noexcept;
constexpr const_iterator cend() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;

// capacity
[[nodiscard]] constexpr bool empty() const noexcept;
constexpr size_type size() const noexcept;
constexpr size_type max_size() const noexcept;

// element access
constexpr reference      operator[](size_type n);
constexpr const_reference operator[](size_type n) const;
constexpr reference      at(size_type n);
constexpr const_reference at(size_type n) const;
constexpr reference      front();
constexpr const_reference front() const;
constexpr reference      back();
constexpr const_reference back() const;

constexpr T * data() noexcept;
constexpr const T * data() const noexcept;
};

template<class T, class... U>
    array(T, U...) -> array<T, 1 + sizeof...(U)>;
}

```

24.3.7.2 Constructors, copy, and assignment

[array.cons]

The conditions for an aggregate (9.4.2) shall be met. Class `array` relies on the implicitly-declared special member functions (11.4.5.2, 11.4.7, 11.4.5.3) to conform to the container requirements table in 24.2. In addition to the requirements specified in the container requirements table, the implicit move constructor and move assignment operator for `array` require that `T` be *Cpp17MoveConstructible* or *Cpp17MoveAssignable*, respectively.

```

template<class T, class... U>
    array(T, U...) -> array<T, 1 + sizeof...(U)>;

Mandates: (is_same_v<T, U> && ...) is true.

```

24.3.7.3 Member functions

[array.members]

```
constexpr size_type size() const noexcept;
```

Returns: N.

```
constexpr T* data() noexcept;
```

```
constexpr const T* data() const noexcept;
```

Returns: A pointer such that `[data(), data() + size())` is a valid range. For a non-empty array, `data() == addressof(front())`.

```
constexpr void fill(const T& u);
```

Effects: As if by `fill_n(begin(), N, u)`.

```
constexpr void swap(array& y) noexcept(is_nothrow_swappable_v<T>);
```

Effects: Equivalent to `swap_ranges(begin(), end(), y.begin())`.

NOTE Unlike the `swap` function for other containers, `array::swap` takes linear time, can exit via an exception, and does not cause iterators to become associated with the other container.

24.3.7.4 Specialized algorithms

[array.special]

```
template<class T, size_t N>
```

```
constexpr void swap(array<T, N>& x, array<T, N>& y) noexcept(noexcept(x.swap(y)));
```

Constraints: `N == 0` or `is_swappable_v<T>` is true.

Effects: As if by `x.swap(y)`.

Complexity: Linear in N.

24.3.7.5 Zero-sized arrays

[array.zero]

`array` shall provide support for the special case `N == 0`.

In the case that `N == 0`, `begin() == end() == unique value`. The return value of `data()` is unspecified.

The effect of calling `front()` or `back()` for a zero-sized array is undefined.

Member function `swap()` shall have a non-throwing exception specification.

24.3.7.6 Array creation functions

[array.creation]

```
template<class T, size_t N>
```

```
constexpr array<remove_cv_t<T>, N> to_array(T (&a)[N]);
```

Mandates: `is_array_v<T>` is false and `is_constructible_v<T, T&>` is true.

Preconditions: T meets the *Cpp17CopyConstructible* requirements.

Returns: `{{ a[0], ..., a[N - 1] }}`.

```
template<class T, size_t N>
```

```
constexpr array<remove_cv_t<T>, N> to_array(T (&&a)[N]);
```

Mandates: `is_array_v<T>` is false and `is_move_constructible_v<T>` is true.

Preconditions: T meets the *Cpp17MoveConstructible* requirements.

Returns: `{{ std::move(a[0]), ..., std::move(a[N - 1]) }}`.

24.3.7.7 Tuple interface

[array.tuple]

```
template<class T, size_t N>
```

```
struct tuple_size<array<T, N>> : integral_constant<size_t, N> { };
```

```
template<size_t I, class T, size_t N>
```

```
struct tuple_element<I, array<T, N>> {
```

```
using type = T;
```

```
};
```

Mandates: `I < N` is true.

```

template<size_t I, class T, size_t N>
constexpr T& get(array<T, N>& a) noexcept;
template<size_t I, class T, size_t N>
constexpr T&& get(array<T, N>&& a) noexcept;
template<size_t I, class T, size_t N>
constexpr const T& get(const array<T, N>& a) noexcept;
template<size_t I, class T, size_t N>
constexpr const T&& get(const array<T, N>&& a) noexcept;

```

Mandates: $I < N$ is true.

Returns: A reference to the I^{th} element of *a*, where indexing is zero-based.

24.3.8 Class template deque

[deque]

24.3.8.1 Overview

[deque.overview]

A deque is a sequence container that supports random access iterators (25.3.5.7). In addition, it supports constant time insert and erase operations at the beginning or the end; insert and erase in the middle take linear time. That is, a deque is especially optimized for pushing and popping elements at the beginning and end. Storage management is handled automatically.

A deque meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), and of a sequence container, including the optional sequence container requirements (24.2.4). Descriptions are provided here only for operations on deque that are not described in one of these tables or for operations where there is additional semantic information.

```

namespace std {
    template<class T, class Allocator = allocator<T>>
    class deque {
    public:
        // types
        using value_type           = T;
        using allocator_type       = Allocator;
        using pointer              = typename allocator_traits<Allocator>::pointer;
        using const_pointer        = typename allocator_traits<Allocator>::const_pointer;
        using reference            = value_type&;
        using const_reference      = const value_type&;
        using size_type            = implementation-defined; // see 24.2
        using difference_type      = implementation-defined; // see 24.2
        using iterator             = implementation-defined; // see 24.2
        using const_iterator       = implementation-defined; // see 24.2
        using reverse_iterator     = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::reverse_iterator<const_iterator>;

        // 24.3.8.2, construct/copy/destroy
        deque() : deque(Allocator()) { }
        explicit deque(const Allocator&);
        explicit deque(size_type n, const Allocator& = Allocator());
        deque(size_type n, const T& value, const Allocator& = Allocator());
        template<class InputIterator>
        deque(InputIterator first, InputIterator last, const Allocator& = Allocator());
        template<container-compatible-range<T> R>
        deque(from_range_t, R&& rg, const Allocator& = Allocator());
        deque(const deque& x);
        deque(deque&&);
        deque(const deque&, const type_identity_t<Allocator>&);
        deque(deque&&, const type_identity_t<Allocator>&);
        deque(initializer_list<T>, const Allocator& = Allocator());

        ~deque();
        deque& operator=(const deque& x);
        deque& operator=(deque&& x)
            noexcept(allocator_traits<Allocator>::is_always_equal::value);
        deque& operator=(initializer_list<T>);
        template<class InputIterator>
        void assign(InputIterator first, InputIterator last);
    };
}

```

```

template<container-compatible-range<T> R>
    void assign_range(R&& rg);
void assign(size_type n, const T& t);
void assign(initializer_list<T>);
allocator_type get_allocator() const noexcept;

template<class InputIterator>
    iterator insert(const_iterator position, InputIterator first, InputIterator last);
template<container-compatible-range<T> R>
    iterator insert_range(const_iterator position, R&& rg);
iterator insert(const_iterator position, initializer_list<T>);

void pop_front();
void pop_back();

```

```

    iterator erase(const_iterator position);
    iterator erase(const_iterator first, const_iterator last);
    void swap(deque&)
        noexcept(allocator_traits<Allocator>::is_always_equal::value);
    void clear() noexcept;
};

template<class InputIterator, class Allocator = allocator<iter-value-type<InputIterator>>>
    deque(InputIterator, InputIterator, Allocator = Allocator())
        -> deque<iter-value-type<InputIterator>, Allocator>;

template<ranges::input_range R, class Allocator = allocator<ranges::range_value_t<R>>>
    deque(from_range_t, R&&, Allocator = Allocator())
        -> deque<ranges::range_value_t<R>, Allocator>;
}

```

24.3.8.2 Constructors, copy, and assignment

[deque.cons]

```
explicit deque(const Allocator&);
```

Effects: Constructs an empty deque, using the specified allocator.

Complexity: Constant.

```
explicit deque(size_type n, const Allocator& = Allocator());
```

Preconditions: T is *Cpp17DefaultInsertable* into *this.

Effects: Constructs a deque with n default-inserted elements using the specified allocator.

Complexity: Linear in n.

```
deque(size_type n, const T& value, const Allocator& = Allocator());
```

Preconditions: T is *Cpp17CopyInsertable* into *this.

Effects: Constructs a deque with n copies of value, using the specified allocator.

Complexity: Linear in n.

```
template<class InputIterator>
    deque(InputIterator first, InputIterator last, const Allocator& = Allocator());
```

Effects: Constructs a deque equal to the range [first, last), using the specified allocator.

Complexity: Linear in distance(first, last).

```
template<container-compatible-range<T> R>
    deque(from_range_t, R&& rg, const Allocator& = Allocator());
```

Effects: Constructs a deque with the elements of the range rg, using the specified allocator.

Complexity: Linear in ranges::distance(rg).

24.3.8.3 Capacity

[deque.capacity]

```
void resize(size_type sz);
```

Preconditions: T is *Cpp17MoveInsertable* and *Cpp17DefaultInsertable* into *this.

Effects: If sz < size(), erases the last size() - sz elements from the sequence. Otherwise, appends sz - size() default-inserted elements to the sequence.

```
void resize(size_type sz, const T& c);
```

Preconditions: T is *Cpp17CopyInsertable* into *this.

Effects: If sz < size(), erases the last size() - sz elements from the sequence. Otherwise, appends sz - size() copies of c to the sequence.

```
void shrink_to_fit();
```

Preconditions: T is *Cpp17MoveInsertable* into *this.

Effects: `shrink_to_fit` is a non-binding request to reduce memory use but does not change the size of the sequence.

NOTE The request is non-binding to allow latitude for implementation-specific optimizations.

If the size is equal to the old capacity, or if an exception is thrown other than by the move constructor of a non-*Cpp17CopyInsertable* `T`, then there are no effects.

Complexity: If the size is not equal to the old capacity, linear in the size of the sequence; otherwise constant.

Remarks: If the size is not equal to the old capacity, then invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator.

24.3.8.4 Modifiers

[deque.modifiers]

```
iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
    iterator insert(const_iterator position,
                    InputIterator first, InputIterator last);
template<container-compatible-range<T> R>
    iterator insert_range(const_iterator position, R&& rg);
iterator insert(const_iterator position, initializer_list<T>);

template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
template<container-compatible-range<T> R>
    void prepend_range(R&& rg);
void push_back(const T& x);
void push_back(T&& x);
template<container-compatible-range<T> R>
    void append_range(R&& rg);
```

Effects: An insertion in the middle of the deque invalidates all the iterators and references to elements of the deque. An insertion at either end of the deque invalidates all the iterators to the deque, but has no effect on the validity of references to elements of the deque.

Complexity: The complexity is linear in the number of elements inserted plus the lesser of the distances to the beginning and end of the deque. Inserting a single element at either the beginning or end of a deque always takes constant time and causes a single call to a constructor of `T`.

Remarks: If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of `T` there are no effects. If an exception is thrown while inserting a single element at either end, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-*Cpp17CopyInsertable* `T`, the effects are unspecified.

```
iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void pop_front();
void pop_back();
```

Effects: An erase operation that erases the last element of a deque invalidates only the past-the-end iterator and all iterators and references to the erased elements. An erase operation that erases the first element of a deque but not the last element invalidates only iterators and references to the erased elements. An erase operation that erases neither the first element nor the last element of a deque invalidates the past-the-end iterator and all iterators and references to all the elements of the deque.

NOTE `pop_front` and `pop_back` are erase operations.

Throws: Nothing unless an exception is thrown by the assignment operator of `T`.

Complexity: The number of calls to the destructor of `T` is the same as the number of elements erased, but the number of calls to the assignment operator of `T` is no more than the lesser of the number of elements before the erased elements and the number of elements after the erased elements.

24.3.8.5 Erasure

[deque.erase]

```
template<class T, class Allocator, class U>
typename deque<T, Allocator>::size_type
erase(deque<T, Allocator>& c, const U& value);
```

Effects: Equivalent to:

```
auto it = remove(c.begin(), c.end(), value);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;
```

```
template<class T, class Allocator, class Predicate>
typename deque<T, Allocator>::size_type
erase_if(deque<T, Allocator>& c, Predicate pred);
```

Effects: Equivalent to:

```
auto it = remove_if(c.begin(), c.end(), pred);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;
```

24.3.9 Class template forward_list

[forward.list]

24.3.9.1 Overview

[forward.list.overview]

A `forward_list` is a container that supports forward iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Fast random access to list elements is not supported.

NOTE 1 It is intended that `forward_list` have zero space or time overhead relative to a hand-written C-style singly linked list. Features that would conflict with that goal have been omitted.

A `forward_list` meets all of the requirements of a container (24.2.2.2), except that the `size()` member function is not provided and `operator==` has linear complexity. A `forward_list` also meets all of the requirements for an allocator-aware container (24.2.2.5). In addition, a `forward_list` provides the `assign` member functions and several of the optional sequence container requirements (24.2.4). Descriptions are provided here only for operations on `forward_list` that are not described in that table or for operations where there is additional semantic information.

NOTE 2 Modifying any list requires access to the element preceding the first element of interest, but in a `forward_list` there is no constant-time way to access a preceding element. For this reason, `erase_after` and `splice_after` take fully-open ranges, not semi-open ranges.

```
namespace std {
    template<class T, class Allocator = allocator<T>>
    class forward_list {
    public:
        // types
        using value_type      = T;
        using allocator_type  = Allocator;
        using pointer         = typename allocator_traits<Allocator>::pointer;
        using const_pointer   = typename allocator_traits<Allocator>::const_pointer;
        using reference       = value_type&;
        using const_reference = const value_type&;
        using size_type       = implementation-defined; // see 24.2
        using difference_type = implementation-defined; // see 24.2
        using iterator        = implementation-defined; // see 24.2
        using const_iterator  = implementation-defined; // see 24.2

        // 24.3.9.2, construct/copy/destroy
        forward_list() : forward_list(Allocator()) { }
        explicit forward_list(const Allocator&);
        explicit forward_list(size_type n, const Allocator& = Allocator());
        forward_list(size_type n, const T& value, const Allocator& = Allocator());
        template<class InputIterator>
        forward_list(InputIterator first, InputIterator last, const Allocator& = Allocator());
```

```

template<container-compatible-range<T> R>
    forward_list(from_range_t, R&& rg, const Allocator& = Allocator());
forward_list(const forward_list& x);
forward_list(forward_list&& x);
forward_list(const forward_list& x, const type_identity_t<Allocator>&);
forward_list(forward_list&& x, const type_identity_t<Allocator>&);
forward_list(initializer_list<T>, const Allocator& = Allocator());
~forward_list();
forward_list& operator=(const forward_list& x);
forward_list& operator=(forward_list&& x)
    noexcept(allocator_traits<Allocator>::is_always_equal::value);
forward_list& operator=(initializer_list<T>);
template<class InputIterator>
    void assign(InputIterator first, InputIterator last);
template<container-compatible-range<T> R>
    void assign_range(R&& rg);
void assign(size_type n, const T& t);
void assign(initializer_list<T>);
allocator_type get_allocator() const noexcept;

// 24.3.9.3, iterators
iterator before_begin() noexcept;
const_iterator before_begin() const noexcept;
iterator begin() noexcept;
const_iterator begin() const noexcept;
iterator end() noexcept;
const_iterator end() const noexcept;

const_iterator cbegin() const noexcept;
const_iterator cbefore_begin() const noexcept;
const_iterator cend() const noexcept;

// capacity
[[nodiscard]] bool empty() const noexcept;
size_type max_size() const noexcept;

// 24.3.9.4, element access
reference front();
const_reference front() const;

// 24.3.9.5, modifiers
template<class... Args> reference emplace_front(Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
template<container-compatible-range<T> R>
    void prepend_range(R&& rg);
void pop_front();

template<class... Args> iterator emplace_after(const_iterator position, Args&&... args);
iterator insert_after(const_iterator position, const T& x);
iterator insert_after(const_iterator position, T&& x);

iterator insert_after(const_iterator position, size_type n, const T& x);
template<class InputIterator>
    iterator insert_after(const_iterator position, InputIterator first, InputIterator last);
iterator insert_after(const_iterator position, initializer_list<T> il);
template<container-compatible-range<T> R>
    iterator insert_range_after(const_iterator position, R&& rg);

iterator erase_after(const_iterator position);
iterator erase_after(const_iterator position, const_iterator last);
void swap(forward_list&)
    noexcept(allocator_traits<Allocator>::is_always_equal::value);

```

```

void resize(size_type sz);
void resize(size_type sz, const value_type& c);
void clear() noexcept;

// 24.3.9.6, forward_list operations
void splice_after(const_iterator position, forward_list& x);
void splice_after(const_iterator position, forward_list&& x);
void splice_after(const_iterator position, forward_list& x, const_iterator i);
void splice_after(const_iterator position, forward_list&& x, const_iterator i);
void splice_after(const_iterator position, forward_list& x,
                  const_iterator first, const_iterator last);
void splice_after(const_iterator position, forward_list&& x,
                  const_iterator first, const_iterator last);

size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);

size_type unique();
template<class BinaryPredicate> size_type unique(BinaryPredicate binary_pred);

void merge(forward_list& x);
void merge(forward_list&& x);
template<class Compare> void merge(forward_list& x, Compare comp);
template<class Compare> void merge(forward_list&& x, Compare comp);

void sort();
template<class Compare> void sort(Compare comp);

void reverse() noexcept;
};

template<class InputIterator, class Allocator = allocator<iter-value-type<InputIterator>>>
    forward_list(InputIterator, InputIterator, Allocator = Allocator())
    -> forward_list<iter-value-type<InputIterator>, Allocator>;

template<ranges::input_range R, class Allocator = allocator<ranges::range_value_t<R>>>
    forward_list(from_range_t, R&&, Allocator = Allocator())
    -> forward_list<ranges::range_value_t<R>, Allocator>;
}

```

An incomplete type *T* may be used when instantiating `forward_list` if the allocator meets the allocator completeness requirements (16.4.4.6.2). *T* shall be complete before any member of the resulting specialization of `forward_list` is referenced.

24.3.9.2 Constructors, copy, and assignment

[forward.list.cons]

```
explicit forward_list(const Allocator&);
```

Effects: Constructs an empty `forward_list` object using the specified allocator.

Complexity: Constant.

```
explicit forward_list(size_type n, const Allocator& = Allocator());
```

Preconditions: *T* is *Cpp17DefaultInsertable* into **this*.

Effects: Constructs a `forward_list` object with *n* default-inserted elements using the specified allocator.

Complexity: Linear in *n*.

```
forward_list(size_type n, const T& value, const Allocator& = Allocator());
```

Preconditions: *T* is *Cpp17CopyInsertable* into **this*.

Effects: Constructs a `forward_list` object with *n* copies of *value* using the specified allocator.

Complexity: Linear in *n*.

```
template<class InputIterator>
forward_list(InputIterator first, InputIterator last, const Allocator& = Allocator());
```

Effects: Constructs a `forward_list` object equal to the range `[first, last)`.

Complexity: Linear in `distance(first, last)`.

```
template<container-compatible-range<T> R>
forward_list(from_range_t, R&& rg, const Allocator& = Allocator());
```

Effects: Constructs a `forward_list` object with the elements of the range `rg`.

Complexity: Linear in `ranges::distance(rg)`.

24.3.9.3 Iterators

[forward.list.iter]

```
iterator before_begin() noexcept;
const_iterator before_begin() const noexcept;
const_iterator cbefore_begin() const noexcept;
```

Effects: `cbefore_begin()` is equivalent to `const_cast<forward_list const&>(*this).before_begin()`.

Returns: A non-dereferenceable iterator that, when incremented, is equal to the iterator returned by `begin()`.

Remarks: `before_begin() == end()` shall equal `false`.

24.3.9.4 Element access

[forward.list.access]

```
reference front();
const_reference front() const;
```

Returns: `*begin()`

24.3.9.5 Modifiers

[forward.list.modifiers]

None of the overloads of `insert_after` shall affect the validity of iterators and references, and `erase_after` shall invalidate only iterators and references to the erased elements. If an exception is thrown during `insert_after` there shall be no effect. Inserting `n` elements into a `forward_list` is linear in `n`, and the number of calls to the copy or move constructor of `T` is exactly equal to `n`. Erasing `n` elements from a `forward_list` is linear in `n` and the number of calls to the destructor of type `T` is exactly equal to `n`.

```
template<class... Args> reference emplace_front(Args&&... args);
```

Effects: Inserts an object of type `value_type` constructed with `value_type(std::forward<Args>(args)...) at the beginning of the list.`

```
void push_front(const T& x);
void push_front(T&& x);
```

Effects: Inserts a copy of `x` at the beginning of the list.

```
template<container-compatible-range<T> R>
void prepend_range(R&& rg);
```

Effects: Inserts a copy of each element of `rg` at the beginning of the list.

NOTE The order of elements is not reversed.

```
void pop_front();
```

Effects: As if by `erase_after(before_begin())`.

```
iterator insert_after(const_iterator position, const T& x);
```

Preconditions: `T` is `Cpp17CopyInsertable` into `forward_list`. `position` is `before_begin()` or is a dereferenceable iterator in the range `[begin(), end())`.

Effects: Inserts a copy of `x` after `position`.

Returns: An iterator pointing to the copy of `x`.

```
iterator insert_after(const_iterator position, T&& x);
```

Preconditions: T is *Cpp17MoveInsertable* into *forward_list*. *position* is *before_begin()* or is a dereferenceable iterator in the range *[begin(), end())*.

Effects: Inserts a copy of *x* after *position*.

Returns: An iterator pointing to the copy of *x*.

```
iterator insert_after(const_iterator position, size_type n, const T& x);
```

Preconditions: T is *Cpp17CopyInsertable* into *forward_list*. *position* is *before_begin()* or is a dereferenceable iterator in the range *[begin(), end())*.

Effects: Inserts *n* copies of *x* after *position*.

Returns: An iterator pointing to the last inserted copy of *x*, or *position* if *n == 0* is true.

```
template<class InputIterator>
```

```
iterator insert_after(const_iterator position, InputIterator first, InputIterator last);
```

Preconditions: T is *Cpp17EmplaceConstructible* into *forward_list* from **first*. *position* is *before_begin()* or is a dereferenceable iterator in the range *[begin(), end())*. Neither *first* nor *last* are iterators in **this*.

Effects: Inserts copies of elements in *[first, last)* after *position*.

Returns: An iterator pointing to the last inserted element, or *position* if *first == last* is true.

```
template<container-compatible-range<T> R>
```

```
iterator insert_range_after(const_iterator position, R&& rg);
```

Preconditions: T is *Cpp17EmplaceConstructible* into *forward_list* from **ranges::begin(rg)*. *position* is *before_begin()* or is a dereferenceable iterator in the range *[begin(), end())*. *rg* and **this* do not overlap.

Effects: Inserts copies of elements in the range *rg* after *position*.

Returns: An iterator pointing to the last inserted element, or *position* if *rg* is empty.

```
iterator insert_after(const_iterator position, initializer_list<T> il);
```

Effects: Equivalent to: *return insert_after(position, il.begin(), il.end());*

```
template<class... Args>
```

```
iterator emplace_after(const_iterator position, Args&&... args);
```

Preconditions: T is *Cpp17EmplaceConstructible* into *forward_list* from *std::forward<Args>(args)...* *position* is *before_begin()* or is a dereferenceable iterator in the range *[begin(), end())*.

Effects: Inserts an object of type *value_type* direct-non-list-initialized with *std::forward<Args>(args)...* after *position*.

Returns: An iterator pointing to the new object.

```
iterator erase_after(const_iterator position);
```

Preconditions: The iterator following *position* is dereferenceable.

Effects: Erases the element pointed to by the iterator following *position*.

Returns: An iterator pointing to the element following the one that was erased, or *end()* if no such element exists.

Throws: Nothing.

```
iterator erase_after(const_iterator position, const_iterator last);
```

Preconditions: All iterators in the range *(position, last)* are dereferenceable.

Effects: Erases the elements in the range *(position, last)*.

Returns: *last*.

Throws: Nothing.

```
void resize(size_type sz);
```

Preconditions: T is *Cpp17DefaultInsertable* into *this.

Effects: If `sz < distance(begin(), end())`, erases the last `distance(begin(), end()) - sz` elements from the list. Otherwise, inserts `sz - distance(begin(), end())` default-inserted elements at the end of the list.

```
void resize(size_type sz, const value_type& c);
```

Preconditions: T is *Cpp17CopyInsertable* into *this.

Effects: If `sz < distance(begin(), end())`, erases the last `distance(begin(), end()) - sz` elements from the list. Otherwise, inserts `sz - distance(begin(), end())` copies of `c` at the end of the list.

```
void clear() noexcept;
```

Effects: Erases all elements in the range `[begin(), end())`.

Remarks: Does not invalidate past-the-end iterators.

24.3.9.6 Operations

[forward.list.ops]

In this subclause, arguments for a template parameter named `Predicate` or `BinaryPredicate` shall meet the corresponding requirements in 27.2. The semantics of `i + n`, where `i` is an iterator into the list and `n` is an integer, are the same as those of `next(i, n)`. The expression `i - n`, where `i` is an iterator into the list and `n` is an integer, means an iterator `j` such that `j + n == i` is true. For `merge` and `sort`, the definitions and requirements in 27.8 apply.

```
void splice_after(const_iterator position, forward_list& x);
```

```
void splice_after(const_iterator position, forward_list&& x);
```

Preconditions: `position` is `before_begin()` or is a dereferenceable iterator in the range `[begin(), end())`. `get_allocator() == x.get_allocator()` is true. `addressof(x) != this` is true.

Effects: Inserts the contents of `x` after `position` and `x` becomes empty. Pointers and references to the moved elements of `x` now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into `x`.

Throws: Nothing.

Complexity: $\mathcal{O}(\text{distance}(x.\text{begin}(), x.\text{end}()))$

```
void splice_after(const_iterator position, forward_list& x, const_iterator i);
```

```
void splice_after(const_iterator position, forward_list&& x, const_iterator i);
```

Preconditions: `position` is `before_begin()` or is a dereferenceable iterator in the range `[begin(), end())`. The iterator following `i` is a dereferenceable iterator in `x`. `get_allocator() == x.get_allocator()` is true.

Effects: Inserts the element following `i` into *this, following `position`, and removes it from `x`. The result is unchanged if `position == i` or `position == ++i`. Pointers and references to `***i` continue to refer to the same element but as a member of *this. Iterators to `***i` continue to refer to the same element, but now behave as iterators into *this, not into `x`.

Throws: Nothing.

Complexity: $\mathcal{O}(1)$

```
void splice_after(const_iterator position, forward_list& x,
                 const_iterator first, const_iterator last);
```

```
void splice_after(const_iterator position, forward_list&& x,
                 const_iterator first, const_iterator last);
```

Preconditions: `position` is `before_begin()` or is a dereferenceable iterator in the range `[begin(), end())`. `(first, last)` is a valid range in `x`, and all iterators in the range `(first, last)` are dereferenceable. `position` is not an iterator in the range `(first, last)`. `get_allocator() == x.get_allocator()` is true.

Effects: Inserts elements in the range `(first, last)` after `position` and removes the elements from `x`. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

Complexity: $\mathcal{O}(\text{distance}(\text{first}, \text{last}))$

```
size_type remove(const T& value);
```

```
template<class Predicate> size_type remove_if(Predicate pred);
```

Effects: Erases all the elements in the list referred to by a list iterator `i` for which the following conditions hold: `*i == value` (for `remove()`), `pred(*i)` is `true` (for `remove_if()`). Invalidates only the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by the equality comparison or the predicate.

Complexity: Exactly `distance(begin(), end())` applications of the corresponding predicate.

Remarks: Stable (16.4.6.8).

```
size_type unique();
```

```
template<class BinaryPredicate> size_type unique(BinaryPredicate binary_pred);
```

Let `binary_pred` be `equal_to<>{}` for the first overload.

Preconditions: `binary_pred` is an equivalence relation.

Effects: Erases all but the first element from every consecutive group of equivalent elements. That is, for a nonempty list, erases all elements referred to by the iterator `i` in the range `[begin() + 1, end())` for which `binary_pred(*i, *(i - 1))` is `true`. Invalidates only the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by the predicate.

Complexity: If `empty()` is `false`, exactly `distance(begin(), end()) - 1` applications of the corresponding predicate, otherwise no applications of the predicate.

```
void merge(forward_list& x);
```

```
void merge(forward_list&& x);
```

```
template<class Compare> void merge(forward_list& x, Compare comp);
```

```
template<class Compare> void merge(forward_list&& x, Compare comp);
```

Let `comp` be `less<>` for the first two overloads.

Preconditions: `*this` and `x` are both sorted with respect to the comparator `comp`, and `get_allocator() == x.get_allocator()` is `true`.

Effects: If `addressof(x) == this`, there are no effects. Otherwise, merges the two sorted ranges `[begin(), end())` and `[x.begin(), x.end())`. The result is a range that is sorted with respect to the comparator `comp`. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

Complexity: At most `distance(begin(), end()) + distance(x.begin(), x.end()) - 1` comparisons if `addressof(x) != this`; otherwise, no comparisons are performed.

Remarks: Stable (16.4.6.8). If `addressof(x) != this`, `x` is empty after the merge. No elements are copied by this operation. If an exception is thrown other than by a comparison, there are no effects.

```
void sort();
```

```
template<class Compare> void sort(Compare comp);
```

Effects: Sorts the list according to the `operator<` or the `comp` function object. If an exception is thrown, the order of the elements in `*this` is unspecified. Does not affect the validity of iterators and references.

Complexity: Approximately $N \log N$ comparisons, where N is `distance(begin(), end())`.

Remarks: Stable (16.4.6.8).

```
void reverse() noexcept;
```

Effects: Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

Complexity: Linear time.

24.3.9.7 Erasure

[forward.list.erase]

```
template<class T, class Allocator, class U>
typename forward_list<T, Allocator>::size_type
erase(forward_list<T, Allocator>& c, const U& value);
```

Effects: Equivalent to: `return erase_if(c, [&](auto& elem) { return elem == value; });`

```
template<class T, class Allocator, class Predicate>
typename forward_list<T, Allocator>::size_type
erase_if(forward_list<T, Allocator>& c, Predicate pred);
```

Effects: Equivalent to: `return c.remove_if(pred);`

24.3.10 Class template list

[list]

24.3.10.1 Overview

[list.overview]

A `list` is a sequence container that supports bidirectional iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Unlike vectors (24.3.11) and deques (24.3.8), fast random access to list elements is not supported, but many algorithms only need sequential access anyway.

A `list` meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), and of a sequence container, including most of the optional sequence container requirements (24.2.4). The exceptions are the `operator[]` and `at` member functions, which are not provided.²⁰⁹ Descriptions are provided here only for operations on `list` that are not described in one of these tables or for operations where there is additional semantic information.

```
namespace std {
    template<class T, class Allocator = allocator<T>>
    class list {
    public:
        // types
        using value_type           = T;
        using allocator_type       = Allocator;
        using pointer              = typename allocator_traits<Allocator>::pointer;
        using const_pointer        = typename allocator_traits<Allocator>::const_pointer;
        using reference            = value_type&;
        using const_reference      = const value_type&;
        using size_type            = implementation-defined; // see 24.2
        using difference_type      = implementation-defined; // see 24.2
        using iterator             = implementation-defined; // see 24.2
        using const_iterator       = implementation-defined; // see 24.2
        using reverse_iterator     = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::reverse_iterator<const_iterator>;

        // 24.3.10.2, construct/copy/destroy
        list() : list(Allocator()) { }
        explicit list(const Allocator&);
        explicit list(size_type n, const Allocator& = Allocator());
        list(size_type n, const T& value, const Allocator& = Allocator());
        template<class InputIterator>
        list(InputIterator first, InputIterator last, const Allocator& = Allocator());
        template<container-compatible-range<T> R>
        list(from_range_t, R&& rg, const Allocator& = Allocator());
        list(const list& x);
        list(list&& x);
        list(const list&, const type_identity_t<Allocator>&);
    };
};
```

²⁰⁹) These member functions are only provided by containers whose iterators are random access iterators.

```

list(list&&, const type_identity_t<Allocator>&);
list(initializer_list<T>, const Allocator& = Allocator());
~list();
list& operator=(const list& x);
list& operator=(list&& x)
    noexcept(allocator_traits<Allocator>::is_always_equal::value);
list& operator=(initializer_list<T>);
template<class InputIterator>
    void assign(InputIterator first, InputIterator last);
template<container-compatible-range<T> R>
    void assign_range(R&& rg);
void assign(size_type n, const T& t);
void assign(initializer_list<T>);
allocator_type get_allocator() const noexcept;

// iterators
iterator          begin() noexcept;
const_iterator    begin() const noexcept;
iterator          end() noexcept;
const_iterator    end() const noexcept;
reverse_iterator  rbegin() noexcept;
const_reverse_iterator rbegin() const noexcept;
reverse_iterator  rend() noexcept;
const_reverse_iterator rend() const noexcept;

const_iterator    cbegin() const noexcept;
const_iterator    cend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

// 24.3.10.3, capacity
[[nodiscard]] bool empty() const noexcept;
size_type size() const noexcept;
size_type max_size() const noexcept;
void        resize(size_type sz);
void        resize(size_type sz, const T& c);

// element access
reference      front();
const_reference front() const;
reference      back();
const_reference back() const;

// 24.3.10.4, modifiers
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
template<container-compatible-range<T> R>
    void prepend_range(R&& rg);
void pop_front();
void push_back(const T& x);
void push_back(T&& x);
template<container-compatible-range<T> R>
    void append_range(R&& rg);
void pop_back();

template<class... Args> iterator emplace(const_iterator position, Args&&... args);
iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
    iterator insert(const_iterator position, InputIterator first, InputIterator last);

```

```

template<container-compatible-range<T> R>
    iterator insert_range(const_iterator position, R&& rg);
iterator insert(const_iterator position, initializer_list<T> il);

iterator erase(const_iterator position);
iterator erase(const_iterator position, const_iterator last);
void swap(list&) noexcept(allocator_traits<Allocator>::is_always_equal::value);
void clear() noexcept;

// 24.3.10.5, list operations
void splice(const_iterator position, list& x);
void splice(const_iterator position, list&& x);
void splice(const_iterator position, list& x, const_iterator i);
void splice(const_iterator position, list&& x, const_iterator i);
void splice(const_iterator position, list& x, const_iterator first, const_iterator last);
void splice(const_iterator position, list&& x, const_iterator first, const_iterator last);

size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);

size_type unique();
template<class BinaryPredicate>
    size_type unique(BinaryPredicate binary_pred);

void merge(list& x);
void merge(list&& x);
template<class Compare> void merge(list& x, Compare comp);
template<class Compare> void merge(list&& x, Compare comp);

void sort();
template<class Compare> void sort(Compare comp);

void reverse() noexcept;
};

template<class InputIterator, class Allocator = allocator<iter-value-type<InputIterator>>>
    list(InputIterator, InputIterator, Allocator = Allocator())
    -> list<iter-value-type<InputIterator>, Allocator>;

template<ranges::input_range R, class Allocator = allocator<ranges::range_value_t<R>>>
    list(from_range_t, R&&, Allocator = Allocator())
    -> list<ranges::range_value_t<R>, Allocator>;
}

```

An incomplete type *T* may be used when instantiating `list` if the allocator meets the allocator completeness requirements (16.4.4.6.2). *T* shall be complete before any member of the resulting specialization of `list` is referenced.

24.3.10.2 Constructors, copy, and assignment

[list.cons]

```
explicit list(const Allocator&);
```

Effects: Constructs an empty list, using the specified allocator.

Complexity: Constant.

```
explicit list(size_type n, const Allocator& = Allocator());
```

Preconditions: *T* is *Cpp17DefaultInsertable* into **this*.

Effects: Constructs a list with *n* default-inserted elements using the specified allocator.

Complexity: Linear in *n*.

```
list(size_type n, const T& value, const Allocator& = Allocator());
```

Preconditions: *T* is *Cpp17CopyInsertable* into **this*.

Effects: Constructs a list with *n* copies of *value*, using the specified allocator.

Complexity: Linear in n .

```
template<class InputIterator>
list(InputIterator first, InputIterator last, const Allocator& = Allocator());
```

Effects: Constructs a list equal to the range $[first, last)$.

Complexity: Linear in $distance(first, last)$.

```
template<container-compatible-range<T> R>
list(from_range_t, R&& rg, const Allocator& = Allocator());
```

Effects: Constructs a list object with the elements of the range rg .

Complexity: Linear in $ranges::distance(rg)$.

24.3.10.3 Capacity

[list.capacity]

```
void resize(size_type sz);
```

Preconditions: T is *Cpp17DefaultInsertable* into $*this$.

Effects: If $size() < sz$, appends $sz - size()$ default-inserted elements to the sequence. If $sz \leq size()$, equivalent to:

```
list<T>::iterator it = begin();
advance(it, sz);
erase(it, end());
```

```
void resize(size_type sz, const T& c);
```

Preconditions: T is *Cpp17CopyInsertable* into $*this$.

Effects: As if by:

```
if (sz > size())
    insert(end(), sz-size(), c);
else if (sz < size()) {
    iterator i = begin();
    advance(i, sz);
    erase(i, end());
}
else
    ; // do nothing
```

24.3.10.4 Modifiers

[list.modifiers]

```
iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
```

```
    iterator insert(const_iterator position, InputIterator first,
                    InputIterator last);
```

```
template<container-compatible-range<T> R>
    iterator insert_range(const_iterator position, R&& rg);
iterator insert(const_iterator position, initializer_list<T>);
```

```
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
template<container-compatible-range<T> R>
    void prepend_range(R&& rg);
void push_back(const T& x);
void push_back(T&& x);
template<container-compatible-range<T> R>
    void append_range(R&& rg);
```

Complexity: Insertion of a single element into a list takes constant time and exactly one call to a constructor of T . Insertion of multiple elements into a list is linear in the number of elements inserted,

and the number of calls to the copy constructor or move constructor of `T` is exactly equal to the number of elements inserted.

Remarks: Does not affect the validity of iterators and references. If an exception is thrown there are no effects.

```
iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
```

```
void pop_front();
void pop_back();
void clear() noexcept;
```

Effects: Invalidates only the iterators and references to the erased elements.

Throws: Nothing.

Complexity: Erasing a single element is a constant time operation with a single call to the destructor of `T`. Erasing a range in a list is linear time in the size of the range and the number of calls to the destructor of type `T` is exactly equal to the size of the range.

24.3.10.5 Operations

[list.ops]

Since lists allow fast insertion and erasing from the middle of a list, certain operations are provided specifically for them.²¹⁰ In this subclause, arguments for a template parameter named `Predicate` or `BinaryPredicate` shall meet the corresponding requirements in 27.2. The semantics of `i + n` and `i - n`, where `i` is an iterator into the list and `n` is an integer, are the same as those of `next(i, n)` and `prev(i, n)`, respectively. For `merge` and `sort`, the definitions and requirements in 27.8 apply.

`list` provides three splice operations that destructively move elements from one list to another. The behavior of splice operations is undefined if `get_allocator() != x.get_allocator()`.

```
void splice(const_iterator position, list& x);
void splice(const_iterator position, list&& x);
```

Preconditions: `addressof(x) != this` is true.

Effects: Inserts the contents of `x` before `position` and `x` becomes empty. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

Throws: Nothing.

Complexity: Constant time.

```
void splice(const_iterator position, list& x, const_iterator i);
void splice(const_iterator position, list&& x, const_iterator i);
```

Preconditions: `i` is a valid dereferenceable iterator of `x`.

Effects: Inserts an element pointed to by `i` from list `x` before `position` and removes the element from `x`. The result is unchanged if `position == i` or `position == ++i`. Pointers and references to `*i` continue to refer to this same element but as a member of `*this`. Iterators to `*i` (including `i` itself) continue to refer to the same element, but now behave as iterators into `*this`, not into `x`.

Throws: Nothing.

Complexity: Constant time.

```
void splice(const_iterator position, list& x, const_iterator first,
           const_iterator last);
void splice(const_iterator position, list&& x, const_iterator first,
           const_iterator last);
```

Preconditions: `[first, last)` is a valid range in `x`. `position` is not an iterator in the range `[first, last)`.

Effects: Inserts elements in the range `[first, last)` before `position` and removes the elements from `x`. Pointers and references to the moved elements of `x` now refer to those same elements but as members

²¹⁰) As specified in 16.4.4.6, the requirements in this Clause apply only to lists whose allocators compare equal.

of **this*. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into **this*, not into *x*.

Throws: Nothing.

Complexity: Constant time if `addressof(x) == this`; otherwise, linear time.

```
size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);
```

Effects: Erases all the elements in the list referred to by a list iterator *i* for which the following conditions hold: **i == value*, *pred(*i) != false*. Invalidates only the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by **i == value* or *pred(*i) != false*.

Complexity: Exactly `size()` applications of the corresponding predicate.

Remarks: Stable (16.4.6.8).

```
size_type unique();
template<class BinaryPredicate> size_type unique(BinaryPredicate binary_pred);
```

Let `binary_pred` be `equal_to<>{}` for the first overload.

Preconditions: `binary_pred` is an equivalence relation.

Effects: Erases all but the first element from every consecutive group of equivalent elements. That is, for a nonempty list, erases all elements referred to by the iterator *i* in the range `[begin() + 1, end())` for which `binary_pred(*i, *(i - 1))` is true. Invalidates only the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by the predicate.

Complexity: If `empty()` is false, exactly `size() - 1` applications of the corresponding predicate, otherwise no applications of the predicate.

```
void merge(list& x);
void merge(list&& x);
template<class Compare> void merge(list& x, Compare comp);
template<class Compare> void merge(list&& x, Compare comp);
```

Let `comp` be `less<>` for the first two overloads.

Preconditions: **this* and *x* are both sorted with respect to the comparator `comp`, and `get_allocator() == x.get_allocator()` is true.

Effects: If `addressof(x) == this`, there are no effects. Otherwise, merges the two sorted ranges `[begin(), end())` and `[x.begin(), x.end())`. The result is a range that is sorted with respect to the comparator `comp`. Pointers and references to the moved elements of *x* now refer to those same elements but as members of **this*. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into **this*, not into *x*.

Complexity: At most `size() + x.size() - 1` comparisons if `addressof(x) != this`; otherwise, no comparisons are performed.

Remarks: Stable (16.4.6.8). If `addressof(x) != this`, *x* is empty after the merge. No elements are copied by this operation. If an exception is thrown other than by a comparison there are no effects.

```
void reverse() noexcept;
```

Effects: Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

Complexity: Linear time.

```
void sort();
```

```
template<class Compare> void sort(Compare comp);
```

Effects: Sorts the list according to the operator< or a Compare function object. If an exception is thrown, the order of the elements in *this is unspecified. Does not affect the validity of iterators and references.

Complexity: Approximately $N \log N$ comparisons, where $N == \text{size}()$.

Remarks: Stable (16.4.6.8).

24.3.10.6 Erasure

[list.erasure]

```
template<class T, class Allocator, class U>
typename list<T, Allocator>::size_type
erase(list<T, Allocator>& c, const U& value);
```

Effects: Equivalent to: `return erase_if(c, [&](auto& elem) { return elem == value; });`

```
template<class T, class Allocator, class Predicate>
typename list<T, Allocator>::size_type
erase_if(list<T, Allocator>& c, Predicate pred);
```

Effects: Equivalent to: `return c.remove_if(pred);`

24.3.11 Class template vector

[vector]

24.3.11.1 Overview

[vector.overview]

A **vector** is a sequence container that supports (amortized) constant time insert and erase operations at the end; insert and erase in the middle take linear time. Storage management is handled automatically, though hints can be given to improve efficiency.

A **vector** meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), of a sequence container, including most of the optional sequence container requirements (24.2.4), and, for an element type other than `bool`, of a contiguous container (24.2.2.2). The exceptions are the `push_front`, `prepend_range`, `pop_front`, and `emplace_front` member functions, which are not provided. Descriptions are provided here only for operations on **vector** that are not described in one of these tables or for operations where there is additional semantic information.

The types `iterator` and `const_iterator` meet the `constexpr` iterator requirements (25.3.1).

```
namespace std {
    template<class T, class Allocator = allocator<T>>
    class vector {
    public:
        // types
        using value_type           = T;
        using allocator_type       = Allocator;
        using pointer              = typename allocator_traits<Allocator>::pointer;
        using const_pointer        = typename allocator_traits<Allocator>::const_pointer;
        using reference            = value_type&;
        using const_reference      = const value_type&;
        using size_type            = implementation-defined; // see 24.2
        using difference_type      = implementation-defined; // see 24.2
        using iterator             = implementation-defined; // see 24.2
        using const_iterator       = implementation-defined; // see 24.2
        using reverse_iterator     = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::reverse_iterator<const_iterator>;

        // 24.3.11.2, construct/copy/destroy
        constexpr vector() noexcept(noexcept(Allocator())) : vector(Allocator()) { }
        constexpr explicit vector(const Allocator&) noexcept;
        constexpr explicit vector(size_type n, const Allocator& = Allocator());
        constexpr vector(size_type n, const T& value, const Allocator& = Allocator());
        template<class InputIterator>
            constexpr vector(InputIterator first, InputIterator last, const Allocator& = Allocator());
        template<container-compatible-range<T> R>
            constexpr vector(from_range_t, R&& rg, const Allocator& = Allocator());
        constexpr vector(const vector& x);
```

```

constexpr vector(vector&&) noexcept;
constexpr vector(const vector&, const type_identity_t<Allocator>&);
constexpr vector(vector&&, const type_identity_t<Allocator>&);
constexpr vector(initializer_list<T>, const Allocator& = Allocator());
constexpr ~vector();
constexpr vector& operator=(const vector& x);
constexpr vector& operator=(vector&& x)
    noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
             allocator_traits<Allocator>::is_always_equal::value);

// element access
constexpr reference       operator[](size_type n);
constexpr const_reference operator[](size_type n) const;
constexpr const_reference at(size_type n) const;
constexpr reference       at(size_type n);
constexpr reference       front();
constexpr const_reference front() const;
constexpr reference       back();
constexpr const_reference back() const;

// 24.3.11.4, data access
constexpr T*          data() noexcept;
constexpr const T* data() const noexcept;

// 24.3.11.5, modifiers
template<class... Args> constexpr reference emplace_back(Args&&... args);
constexpr void push_back(const T& x);
constexpr void push_back(T&& x);
template<container-compatible-range<T> R>
    constexpr void append_range(R&& rg);
constexpr void pop_back();

```

```

template<class... Args> constexpr iterator emplace(const_iterator position, Args&&... args);
constexpr iterator insert(const_iterator position, const T& x);
constexpr iterator insert(const_iterator position, T&& x);
constexpr iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
    constexpr iterator insert(const_iterator position,
                             InputIterator first, InputIterator last);
template<container-compatible-range<T> R>
    constexpr iterator insert_range(const_iterator position, R&& rg);
constexpr iterator insert(const_iterator position, initializer_list<T> il);
constexpr iterator erase(const_iterator position);
constexpr iterator erase(const_iterator first, const_iterator last);
constexpr void swap(vector&)
    noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
             allocator_traits<Allocator>::is_always_equal::value);
constexpr void clear() noexcept;
};

template<class InputIterator, class Allocator = allocator<iter-value-type<InputIterator>>>
    vector(InputIterator, InputIterator, Allocator = Allocator())
    -> vector<iter-value-type<InputIterator>, Allocator>;

template<ranges::input_range R, class Allocator = allocator<ranges::range_value_t<R>>>
    vector(from_range_t, R&&, Allocator = Allocator())
    -> vector<ranges::range_value_t<R>, Allocator>;
}

```

An incomplete type *T* may be used when instantiating `vector` if the allocator meets the allocator completeness requirements (16.4.4.6.2). *T* shall be complete before any member of the resulting specialization of `vector` is referenced.

24.3.11.2 Constructors

[vector.cons]

```
constexpr explicit vector(const Allocator&) noexcept;
```

Effects: Constructs an empty `vector`, using the specified allocator.

Complexity: Constant.

```
constexpr explicit vector(size_type n, const Allocator& = Allocator());
```

Preconditions: *T* is *Cpp17DefaultInsertable* into **this*.

Effects: Constructs a `vector` with *n* default-inserted elements using the specified allocator.

Complexity: Linear in *n*.

```
constexpr vector(size_type n, const T& value,
                 const Allocator& = Allocator());
```

Preconditions: *T* is *Cpp17CopyInsertable* into **this*.

Effects: Constructs a `vector` with *n* copies of *value*, using the specified allocator.

Complexity: Linear in *n*.

```
template<class InputIterator>
    constexpr vector(InputIterator first, InputIterator last,
                    const Allocator& = Allocator());
```

Effects: Constructs a `vector` equal to the range `[first, last)`, using the specified allocator.

Complexity: Makes only *N* calls to the copy constructor of *T* (where *N* is the distance between `first` and `last`) and no reallocations if iterators `first` and `last` are of forward, bidirectional, or random access categories. It makes order *N* calls to the copy constructor of *T* and order $\log N$ reallocations if they are just input iterators.

```
template<container-compatible-range<T> R>
    constexpr vector(from_range_t, R&& rg, const Allocator& = Allocator());
```

Effects: Constructs a `vector` object with the elements of the range *rg*, using the specified allocator.

Complexity: Initializes exactly N elements from the results of dereferencing successive iterators of `rg`, where N is `ranges::distance(rg)`. Performs no reallocations if `R` models `ranges::forward_range` or `ranges::sized_range`; otherwise, performs order $\log N$ reallocations and order N calls to the copy or move constructor of `T`.

24.3.11.3 Capacity

[vector.capacity]

```
constexpr size_type capacity() const noexcept;
```

Returns: The total number of elements that the vector can hold without requiring reallocation.

Complexity: Constant time.

```
constexpr void reserve(size_type n);
```

Preconditions: `T` is `Cpp17MoveInsertable` into `*this`.

Effects: A directive that informs a `vector` of a planned change in size, so that it can manage the storage allocation accordingly. After `reserve()`, `capacity()` is greater or equal to the argument of `reserve` if reallocation happens; and equal to the previous value of `capacity()` otherwise. Reallocation happens at this point if and only if the current capacity is less than the argument of `reserve()`. If an exception is thrown other than by the move constructor of a non-`Cpp17CopyInsertable` type, there are no effects.

Throws: `length_error` if $n > \text{max\_size}()$.²¹¹

Complexity: It does not change the size of the sequence and takes at most linear time in the size of the sequence.

Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator.

NOTE 1 If no reallocation happens, they remain valid.

No reallocation shall take place during insertions that happen after a call to `reserve()` until an insertion would make the size of the vector greater than the value of `capacity()`.

```
constexpr void shrink_to_fit();
```

Preconditions: `T` is `Cpp17MoveInsertable` into `*this`.

Effects: `shrink_to_fit` is a non-binding request to reduce `capacity()` to `size()`.

NOTE 2 The request is non-binding to allow latitude for implementation-specific optimizations.

It does not increase `capacity()`, but may reduce `capacity()` by causing reallocation. If an exception is thrown other than by the move constructor of a non-`Cpp17CopyInsertable` `T` there are no effects.

Complexity: If reallocation happens, linear in the size of the sequence.

Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence as well as the past-the-end iterator.

NOTE 3 If no reallocation happens, they remain valid.

```
constexpr void swap(vector& x)
    noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
             allocator_traits<Allocator>::is_always_equal::value);
```

Effects: Exchanges the contents and `capacity()` of `*this` with that of `x`.

Complexity: Constant time.

```
constexpr void resize(size_type sz);
```

Preconditions: `T` is `Cpp17MoveInsertable` and `Cpp17DefaultInsertable` into `*this`.

Effects: If $sz < \text{size}()$, erases the last $\text{size}() - sz$ elements from the sequence. Otherwise, appends $sz - \text{size}()$ default-inserted elements to the sequence.

Remarks: If an exception is thrown other than by the move constructor of a non-`Cpp17CopyInsertable` `T` there are no effects.

²¹¹) `reserve()` uses `Allocator::allocate()` which can throw an appropriate exception.

```
constexpr void resize(size_type sz, const T& c);
```

Preconditions: T is *Cpp17CopyInsertable* into *this.

Effects: If `sz < size()`, erases the last `size() - sz` elements from the sequence. Otherwise, appends `sz - size()` copies of `c` to the sequence.

Remarks: If an exception is thrown there are no effects.

24.3.11.4 Data

[vector.data]

```
constexpr T*      data() noexcept;
constexpr const T* data() const noexcept;
```

Returns: A pointer such that `[data(), data() + size())` is a valid range. For a non-empty vector, `data() == addressof(front())`.

Complexity: Constant time.

24.3.11.5 Modifiers

[vector.modifiers]

```
constexpr iterator insert(const_iterator position, const T& x);
constexpr iterator insert(const_iterator position, T&& x);
constexpr iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
    constexpr iterator insert(const_iterator position, InputIterator first, InputIterator last);
template<container-compatible-range<T> R>
    constexpr iterator insert_range(const_iterator position, R&& rg);
constexpr iterator insert(const_iterator position, initializer_list<T>);

template<class... Args> constexpr reference emplace_back(Args&&... args);
template<class... Args> constexpr iterator emplace(const_iterator position, Args&&... args);
constexpr void push_back(const T& x);
constexpr void push_back(T&& x);
template<container-compatible-range<T> R>
    constexpr void append_range(R&& rg);
```

Complexity: If reallocation happens, linear in the number of elements of the resulting vector; otherwise, linear in the number of elements inserted plus the distance to the end of the vector.

Remarks: Causes reallocation if the new size is greater than the old capacity. Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator. If no reallocation happens, then references, pointers, and iterators before the insertion point remain valid but those at or after the insertion point, including the past-the-end iterator, are invalidated. If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of T or by any *InputIterator* operation there are no effects. If an exception is thrown while inserting a single element at the end and T is *Cpp17CopyInsertable* or *is_nothrow_move_constructible_v<T>* is true, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-*Cpp17CopyInsertable* T, the effects are unspecified.

```
constexpr iterator erase(const_iterator position);
constexpr iterator erase(const_iterator first, const_iterator last);
constexpr void pop_back();
```

Effects: Invalidates iterators and references at or after the point of the erase.

Throws: Nothing unless an exception is thrown by the assignment operator or move assignment operator of T.

Complexity: The destructor of T is called the number of times equal to the number of the elements erased, but the assignment operator of T is called the number of times equal to the number of elements in the vector after the erased elements.

24.3.11.6 Erasure

[vector.erase]

```
template<class T, class Allocator, class U>
    constexpr typename vector<T, Allocator>::size_type
        erase(vector<T, Allocator>& c, const U& value);
```

Effects: Equivalent to:

```

    auto it = remove(c.begin(), c.end(), value);
    auto r = distance(it, c.end());
    c.erase(it, c.end());
    return r;

```

```

template<class T, class Allocator, class Predicate>
constexpr typename vector<T, Allocator>::size_type
erase_if(vector<T, Allocator>& c, Predicate pred);

```

Effects: Equivalent to:

```

    auto it = remove_if(c.begin(), c.end(), pred);
    auto r = distance(it, c.end());
    c.erase(it, c.end());
    return r;

```

24.3.12 Specialization of vector for bool

[vector.bool]

24.3.12.1 Partial class template specialization vector<bool, Allocator>

[vector.bool.pspc]

To optimize space allocation, a partial specialization of vector for bool elements is provided:

```

namespace std {
    template<class Allocator>
    class vector<bool, Allocator> {
    public:
        // types
        using value_type          = bool;
        using allocator_type      = Allocator;
        using pointer             = implementation-defined;
        using const_pointer       = implementation-defined;
        using const_reference     = bool;
        using size_type           = implementation-defined; // see 24.2
        using difference_type     = implementation-defined; // see 24.2
        using iterator            = implementation-defined; // see 24.2
        using const_iterator      = implementation-defined; // see 24.2
        using reverse_iterator    = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::reverse_iterator<const_iterator>;

        // bit reference
        class reference {
            friend class vector;
            constexpr reference() noexcept;

        public:
            constexpr reference(const reference&) = default;
            constexpr ~reference();
            constexpr operator bool() const noexcept;
            constexpr reference& operator=(bool x) noexcept;
            constexpr reference& operator=(const reference& x) noexcept;
            constexpr const reference& operator=(bool x) const noexcept;
            constexpr void flip() noexcept; // flips the bit
        };

        // construct/copy/destroy
        constexpr vector() noexcept(noexcept(Allocator())) : vector(Allocator()) { }
        constexpr explicit vector(const Allocator&) noexcept;
        constexpr explicit vector(size_type n, const Allocator& = Allocator());
        constexpr vector(size_type n, const bool& value, const Allocator& = Allocator());
        template<class InputIterator>
            constexpr vector(InputIterator first, InputIterator last, const Allocator& = Allocator());
        template<container-compatible-range<bool> R>
            constexpr vector(from_range_t, R&& rg, const Allocator& = Allocator());
        constexpr vector(const vector& x);
        constexpr vector(vector&& x) noexcept;
        constexpr vector(const vector&, const type_identity_t<Allocator>&);
        constexpr vector(vector&&, const type_identity_t<Allocator>&);

```

```

constexpr vector(initializer_list<bool>, const Allocator& = Allocator());
constexpr ~vector();
constexpr vector& operator=(const vector& x);
constexpr vector& operator=(vector&& x)
    noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
              allocator_traits<Allocator>::is_always_equal::value);
constexpr vector& operator=(initializer_list<bool>);
template<class InputIterator>
    constexpr void assign(InputIterator first, InputIterator last);
template<container-compatible-range<bool> R>
    constexpr void assign_range(R&& rg);
constexpr void assign(size_type n, const bool& t);
constexpr void assign(initializer_list<bool>);
constexpr allocator_type get_allocator() const noexcept;

// iterators
constexpr iterator          begin() noexcept;
constexpr const_iterator    begin() const noexcept;
constexpr iterator          end() noexcept;
constexpr const_iterator    end() const noexcept;
constexpr reverse_iterator  rbegin() noexcept;
constexpr const_reverse_iterator rbegin() const noexcept;
constexpr reverse_iterator  rend() noexcept;
constexpr const_reverse_iterator rend() const noexcept;

constexpr const_iterator    cbegin() const noexcept;
constexpr const_iterator    cend() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;

// capacity
[[nodiscard]] constexpr bool empty() const noexcept;
constexpr size_type size() const noexcept;
constexpr size_type max_size() const noexcept;
constexpr size_type capacity() const noexcept;
constexpr void        resize(size_type sz, bool c = false);
constexpr void        reserve(size_type n);
constexpr void        shrink_to_fit();

// element access
constexpr reference        operator[](size_type n);
constexpr const_reference  operator[](size_type n) const;
constexpr const_reference  at(size_type n) const;
constexpr reference        at(size_type n);
constexpr reference        front();
constexpr const_reference  front() const;
constexpr reference        back();
constexpr const_reference  back() const;

// modifiers
template<class... Args> constexpr reference emplace_back(Args&&... args);
constexpr void push_back(const bool& x);
template<container-compatible-range<bool> R>
    constexpr void append_range(R&& rg);
constexpr void pop_back();
template<class... Args> constexpr iterator emplace(const_iterator position, Args&&... args);
constexpr iterator insert(const_iterator position, const bool& x);
constexpr iterator insert(const_iterator position, size_type n, const bool& x);
template<class InputIterator>
    constexpr iterator insert(const_iterator position,
                              InputIterator first, InputIterator last);
template<container-compatible-range<bool> R>
    constexpr iterator insert_range(const_iterator position, R&& rg);
constexpr iterator insert(const_iterator position, initializer_list<bool> il);

```

```

constexpr iterator erase(const_iterator position);
constexpr iterator erase(const_iterator first, const_iterator last);
constexpr void swap(vector&)
    noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
              allocator_traits<Allocator>::is_always_equal::value);
static constexpr void swap(reference x, reference y) noexcept;
constexpr void flip() noexcept;           // flips all bits
constexpr void clear() noexcept;
};
}

```

Unless described below, all operations have the same requirements and semantics as the primary `vector` template, except that operations dealing with the `bool` value type map to bit values in the container storage and `allocator_traits::construct` (20.2.9.3) is not used to construct these values.

There is no requirement that the data be stored as a contiguous allocation of `bool` values. A space-optimized representation of bits is recommended instead.

reference is a class that simulates the behavior of references of a single bit in `vector<bool>`. The conversion function returns **true** when the bit is set, and **false** otherwise. The assignment operators set the bit when the argument is (convertible to) **true** and clear it otherwise. **flip** reverses the state of the bit.

```
constexpr void flip() noexcept;
```

Effects: Replaces each element in the container with its complement.

```
static constexpr void swap(reference x, reference y) noexcept;
```

Effects: Exchanges the contents of `x` and `y` as if by:

```

bool b = x;
x = y;
y = b;

```

```
template<class Allocator> struct hash<vector<bool, Allocator>>;
```

The specialization is enabled (22.10.19).

```

template<class T>
constexpr bool is-vector-bool-reference = see below;

```

The expression `is-vector-bool-reference<T>` is true if `T` denotes the type `vector<bool, Alloc>::reference` for some type `Alloc` and `vector<bool, Alloc>` is not a program-defined specialization.

24.3.12.2 Formatter specialization for `vector<bool>`

[vector.bool.fmt]

```

namespace std {
    template<class T, class charT>
        requires is-vector-bool-reference<T>
        struct formatter<T, charT> {
        private:
            formatter<bool, charT> underlying_;           // exposition only

        public:
            template<class ParseContext>
                constexpr typename ParseContext::iterator
                    parse(ParseContext& ctx);

            template<class FormatContext>
                typename FormatContext::iterator
                    format(const T& ref, FormatContext& ctx) const;
        };
}

```

```

template<class ParseContext>
constexpr typename ParseContext::iterator
    parse(ParseContext& ctx);

```

Equivalent to: return `underlying_.parse(ctx);`

```
template<class FormatContext>
    typename FormatContext::iterator
    format(const T& ref, FormatContext& ctx) const;

    Equivalent to: return underlying_.format(ref, ctx);
```

24.4 Associative containers

[associative]

24.4.1 General

[associative.general]

The header `<map>` defines the class templates `map` and `multimap`; the header `<set>` defines the class templates `set` and `multiset`.

The following exposition-only alias templates may appear in deduction guides for associative containers:

```
template<class InputIterator>
    using iter-value-type =
        typename iterator_traits<InputIterator>::value_type; // exposition only
template<class InputIterator>
    using iter-key-type = remove_const_t<
        tuple_element_t<0, iter-value-type<InputIterator>>>; // exposition only
template<class InputIterator>
    using iter-mapped-type =
        tuple_element_t<1, iter-value-type<InputIterator>>; // exposition only
template<class InputIterator>
    using iter-to-alloc-type = pair<
        add_const_t<tuple_element_t<0, iter-value-type<InputIterator>>>,
        tuple_element_t<1, iter-value-type<InputIterator>>>; // exposition only
template<ranges::input_range Range>
    using range-key-type =
        remove_const_t<typename ranges::range_value_t<Range>::first_type>; // exposition only
template<ranges::input_range Range>
    using range-mapped-type = typename ranges::range_value_t<Range>::second_type; // exposition only
template<ranges::input_range Range>
    using range-to-alloc-type =
        pair<add_const_t<typename ranges::range_value_t<Range>::first_type>,
            typename ranges::range_value_t<Range>::second_type>; // exposition only
```

24.4.2 Header `<map>` synopsis

[associative.map.syn]

```
#include <compare> // see 17.11.1
#include <initializer_list> // see 17.10.2

namespace std {
    // 24.4.4, class template map
    template<class Key, class T, class Compare = less<Key>,
        class Allocator = allocator<pair<const Key, T>>>
        class map;

    template<class Key, class T, class Compare, class Allocator>
        bool operator==(const map<Key, T, Compare, Allocator>& x,
            const map<Key, T, Compare, Allocator>& y);
    template<class Key, class T, class Compare, class Allocator>
        synth-three-way-result<pair<const Key, T>>
        operator<=>(const map<Key, T, Compare, Allocator>& x,
            const map<Key, T, Compare, Allocator>& y);

    template<class Key, class T, class Compare, class Allocator>
        void swap(map<Key, T, Compare, Allocator>& x,
            map<Key, T, Compare, Allocator>& y)
            noexcept(noexcept(x.swap(y)));

    // 24.4.4.5, erasure for map
    template<class Key, class T, class Compare, class Allocator, class Predicate>
        typename map<Key, T, Compare, Allocator>::size_type
        erase_if(map<Key, T, Compare, Allocator>& c, Predicate pred);
```

```

// 24.4.5, class template multimap
template<class Key, class T, class Compare = less<Key>,
        class Allocator = allocator<pair<const Key, T>>>
    class multimap;

template<class Key, class T, class Compare, class Allocator>
    bool operator==(const multimap<Key, T, Compare, Allocator>& x,
                    const multimap<Key, T, Compare, Allocator>& y);
template<class Key, class T, class Compare, class Allocator>
    synth-three-way-result<pair<const Key, T>>
        operator<=>(const multimap<Key, T, Compare, Allocator>& x,
                    const multimap<Key, T, Compare, Allocator>& y);

template<class Key, class T, class Compare, class Allocator>
    void swap(multimap<Key, T, Compare, Allocator>& x,
              multimap<Key, T, Compare, Allocator>& y)
        noexcept(noexcept(x.swap(y)));

// 24.4.5.4, erasure for multimap
template<class Key, class T, class Compare, class Allocator, class Predicate>
    typename multimap<Key, T, Compare, Allocator>::size_type
        erase_if(multimap<Key, T, Compare, Allocator>& c, Predicate pred);

namespace pmr {

24.4.4 Class template map

[map]

24.4.4.1 Overview

[map.overview]

A **map** is an associative container that supports unique keys (i.e., contains at most one of each key value) and provides for fast retrieval of values of another type *T* based on the keys. The **map** class supports bidirectional iterators.

A **map** meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), and of an associative container (24.2.7). A **map** also provides most operations described in 24.2.7 for unique keys. This means that a **map** supports the **a_uniq** operations in 24.2.7 but not the **a_eq** operations. For a **map**<Key, *T*> the **key_type** is *Key* and the **value_type** is **pair**<const *Key*, *T*>. Descriptions are provided here only for operations on **map** that are not described in one of those tables or for operations where there is additional semantic information.

```

namespace std {
    template<class Key, class T, class Compare = less<Key>,
            class Allocator = allocator<pair<const Key, T>>>
    class map {
    public:
        // types
        using key_type           = Key;
        using mapped_type       = T;
        using value_type        = pair<const Key, T>;
        using key_compare       = Compare;
        using allocator_type    = Allocator;
        using pointer           = typename allocator_traits<Allocator>::pointer;
        using const_pointer     = typename allocator_traits<Allocator>::const_pointer;
        using reference         = value_type&;
        using const_reference   = const value_type&;
        using size_type         = implementation-defined; // see 24.2
        using difference_type    = implementation-defined; // see 24.2
        using iterator          = implementation-defined; // see 24.2
        using const_iterator    = implementation-defined; // see 24.2

}

```

24.4.4.2 Constructors, copy, and assignment**[map.cons]**

```
explicit map(const Compare& comp, const Allocator& = Allocator());
```

Effects: Constructs an empty map using the specified comparison object and allocator.

Complexity: Constant.

```
template<class InputIterator>
```

```
map(InputIterator first, InputIterator last,
    const Compare& comp = Compare(), const Allocator& = Allocator());
```

Effects: Constructs an empty map using the specified comparison object and allocator, and inserts elements from the range `[first, last)`.

Complexity: Linear in N if the range `[first, last)` is already sorted with respect to `comp` and otherwise $N \log N$, where N is `last - first`.

```
template<container-compatible-range<value_type> R>
```

```
map(from_range_t, R&& rg, const Compare& comp = Compare(), const Allocator& = Allocator());
```

Effects: Constructs an empty map using the specified comparison object and allocator, and inserts elements from the range `rg`.

Complexity: Linear in N if `rg` is already sorted with respect to `comp` and otherwise $N \log N$, where N is `ranges::distance(rg)`.

24.4.4.3 Element access**[map.access]**

```
mapped_type& operator[](const key_type& x);
```

Effects: Equivalent to: `return try_emplace(x).first->second;`

```
mapped_type& operator[](key_type&& x);
```

Effects: Equivalent to: `return try_emplace(std::move(x)).first->second;`

```
mapped_type& at(const key_type& x);
```

```
const mapped_type& at(const key_type& x) const;
```

Returns: A reference to the `mapped_type` corresponding to `x` in `*this`.

Throws: An exception object of type `out_of_range` if no such element is present.

Complexity: Logarithmic.

24.4.4.4 Modifiers**[map.modifiers]**

```
template<class P>
```

```
pair<iterator, bool> insert(P&& x);
```

```
template<class P>
```

```
iterator insert(const_iterator position, P&& x);
```

Constraints: `is_constructible_v<value_type, P&&>` is true.

Effects: The first form is equivalent to `return emplace(std::forward<P>(x))`. The second form is equivalent to `return emplace_hint(position, std::forward<P>(x))`.

```
template<class... Args>
```

```
pair<iterator, bool> try_emplace(const key_type& k, Args&&... args);
```

```
template<class... Args>
```

```
iterator try_emplace(const_iterator hint, const key_type& k, Args&&... args);
```

Preconditions: `value_type` is `Cpp17EmplaceConstructible` into map from `piecewise_construct`, `forward_as_tuple(k)`, `forward_as_tuple(std::forward<Args>(args)...)...`.

Effects: If the map already contains an element whose key is equivalent to `k`, there is no effect. Otherwise inserts an object of type `value_type` constructed with `piecewise_construct`, `forward_as_tuple(k)`, `forward_as_tuple(std::forward<Args>(args)...)...`.

Returns: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

Complexity: The same as `emplace` and `emplace_hint`, respectively.

```
template<class... Args>
    pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);
template<class... Args>
    iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);
```

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into map from `piecewise_construct`, `forward_as_tuple(std::move(k))`, `forward_as_tuple(std::forward<Args>(args)...)...`.

Effects: If the map already contains an element whose key is equivalent to `k`, there is no effect. Otherwise inserts an object of type `value_type` constructed with `piecewise_construct`, `forward_as_tuple(std::move(k))`, `forward_as_tuple(std::forward<Args>(args)...)...`.

Returns: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

Complexity: The same as `emplace` and `emplace_hint`, respectively.

```
template<class M>
    pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);
template<class M>
    iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);
```

Mandates: `is_assignable_v<mapped_type&, M&&>` is `true`.

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into map from `k`, `std::forward<M>(obj)`.

Effects: If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::forward<M>(obj)` to `e.second`. Otherwise inserts an object of type `value_type` constructed with `k`, `std::forward<M>(obj)`.

Returns: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

Complexity: The same as `emplace` and `emplace_hint`, respectively.

```
template<class M>
    pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);
template<class M>
    iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);
```

Mandates: `is_assignable_v<mapped_type&, M&&>` is `true`.

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into map from `std::move(k)`, `std::forward<M>(obj)`.

Effects: If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::forward<M>(obj)` to `e.second`. Otherwise inserts an object of type `value_type` constructed with `std::move(k)`, `std::forward<M>(obj)`.

Returns: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

Complexity: The same as `emplace` and `emplace_hint`, respectively.

24.4.4.5 Erasure

[map.erase]

```
template<class Key, class T, class Compare, class Allocator, class Predicate>
    typename map<Key, T, Compare, Allocator>::size_type
    erase_if(map<Key, T, Compare, Allocator>& c, Predicate pred);
```

Effects: Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
return original_size - c.size();
```

24.4.5 Class template multimap**[multimap]****24.4.5.1 Overview****[multimap.overview]**

A **multimap** is an associative container that supports equivalent keys (i.e., possibly containing multiple copies of the same key value) and provides for fast retrieval of values of another type **T** based on the keys. The **multimap** class supports bidirectional iterators.

A **multimap** meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), and of an associative container (24.2.7). A **multimap** also provides most operations described in 24.2.7 for equal keys. This means that a **multimap** supports the **a_eq** operations in 24.2.7 but not the **a_uniq** operations. For a **multimap**<Key,T> the **key_type** is **Key** and the **value_type** is **pair<const Key,T>**. Descriptions are provided here only for operations on **multimap** that are not described in one of those tables or for operations where there is additional semantic information.

```
namespace std {
    template<class Key, class T, class Compare = less<Key>,
            class Allocator = allocator<pair<const Key, T>>>
    class multimap {
    public:
        // types
        using key_type           = Key;
        using mapped_type       = T;
        using value_type        = pair<const Key, T>;
        using key_compare       = Compare;

    multimap(initializer_list<pair<Key, T>>, Allocator)
        -> multimap<Key, T, less<Key>, Allocator>;
}

```

24.4.5.2 Constructors [multimap.cons]

```
explicit multimap(const Compare& comp, const Allocator& = Allocator());
```

Effects: Constructs an empty multimap using the specified comparison object and allocator.

Complexity: Constant.

```

template<class InputIterator>
    multimap(InputIterator first, InputIterator last,
            const Compare& comp = Compare(),
            const Allocator& = Allocator());

```

Effects: Constructs an empty multimap using the specified comparison object and allocator, and inserts elements from the range `[first, last)`.

Complexity: Linear in N if the range `[first, last)` is already sorted with respect to `comp` and otherwise $N \log N$, where N is `last - first`.

```

template<container-compatible-range<value_type> R>
    multimap(from_range_t, R&& rg, const Compare& comp = Compare(), const Allocator& = Allocator());

```

Effects: Constructs an empty multimap using the specified comparison object and allocator, and inserts elements from the range `rg`.

Complexity: Linear in N if `rg` is already sorted with respect to `comp` and otherwise $N \log N$, where N is `ranges::distance(rg)`.

24.4.5.3 Modifiers [multimap.modifiers]

```

template<class P> iterator insert(P&& x);
template<class P> iterator insert(const_iterator position, P&& x);

```

Constraints: `is_constructible_v<value_type, P&&>` is true.

Effects: The first form is equivalent to `return emplace(std::forward<P>(x))`. The second form is equivalent to `return emplace_hint(position, std::forward<P>(x))`.

24.4.5.4 Erasure [multimap.erase]

```

template<class Key, class T, class Compare, class Allocator, class Predicate>
    typename multimap<Key, T, Compare, Allocator>::size_type
    erase_if(multimap<Key, T, Compare, Allocator>& c, Predicate pred);

```

Effects: Equivalent to:

```

auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}

```

```

        ++i;
    }
}
return original_size - c.size();

```

24.4.6 Class template `set`

[set]

24.4.6.1 Overview

[set.overview]

A `set` is an associative container that supports unique keys (i.e., contains at most one of each key value) and provides for fast retrieval of the keys themselves. The `set` class supports bidirectional iterators.

A `set` meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), and of an associative container (24.2.7). A `set` also provides most operations described in 24.2.7 for unique keys. This means that a `set` supports the `a_uniq` operations in 24.2.7 but not the `a_eq` operations. For a `set<Key>` both the `key_type` and `value_type` are `Key`. Descriptions are provided here only for operations on `set` that are not described in one of these tables and for operations where there is additional semantic information.

```

namespace std {
    template<class Key, class Compare = less<Key>,
            class Allocator = allocator<Key>>
    class set {
    public:
        // types
        using key_type           = Key;
        using key_compare        = Compare;
        using value_type         = Key;
        using value_compare      = Compare;
        using allocator_type     = Allocator;

24.4.6.2 Constructors, copy, and assignment

[set.cons]

```
explicit set(const Compare& comp, const Allocator& = Allocator());
```

Effects: Constructs an empty `set` using the specified comparison object and allocator.

Complexity: Constant.

```
template<class InputIterator>
    set(InputIterator first, InputIterator last,
        const Compare& comp = Compare(), const Allocator& = Allocator());
```

Effects: Constructs an empty `set` using the specified comparison object and allocator, and inserts elements from the range `[first, last)`.

Complexity: Linear in N if the range `[first, last)` is already sorted with respect to `comp` and otherwise $N \log N$, where N is `last - first`.

```
template<container-compatible-range<value_type> R>
    set(from_range_t, R&& rg, const Compare& comp = Compare(), const Allocator& = Allocator());
```

Effects: Constructs an empty `set` using the specified comparison object and allocator, and inserts elements from the range `rg`.

Complexity: Linear in N if `rg` is already sorted with respect to `comp` and otherwise $N \log N$, where N is `ranges::distance(rg)`.

24.4.6.3 Erasure

[set.erasure]

```
template<class Key, class Compare, class Allocator, class Predicate>
    typename set<Key, Compare, Allocator>::size_type
    erase_if(set<Key, Compare, Allocator>& c, Predicate pred);
```

Effects: Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
return original_size - c.size();
```

24.4.7 Class template `multiset`

[multiset]

24.4.7.1 Overview

[multiset.overview]

A `multiset` is an associative container that supports equivalent keys (i.e., possibly contains multiple copies of the same key value) and provides for fast retrieval of the keys themselves. The `multiset` class supports bidirectional iterators.

A `multiset` meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), of an associative container (24.2.7). `multiset` also provides most operations described in 24.2.7 for duplicate keys. This means that a `multiset` supports the `a_eq` operations in 24.2.7 but not the `a_uniq` operations. For a `multiset<Key>` both the `key_type` and `value_type` are `Key`. Descriptions are provided here only for operations on `multiset` that are not described in one of these tables and for operations where there is additional semantic information.

```
namespace std {
    template<class Key, class Compare = less<Key>,
            class Allocator = allocator<Key>>
    class multiset {
    public:
        // types
        using key_type          = Key;
```

```

using key_compare          = Compare;
using value_type           = Key;
using value_compare        = Compare;
using allocator_type       = Allocator;
using pointer              = typename allocator_traits<Allocator>::pointer;
using const_pointer        = typename allocator_traits<Allocator>::const_pointer;
using reference             = value_type&;
using const_reference      = const value_type&;
using size_type            = implementation-defined; // see 24.2
using difference_type      = implementation-defined; // see 24.2
using iterator             = implementation-defined; // see 24.2
using const_iterator       = implementation-defined; // see 24.2
using reverse_iterator     = std::reverse_iterator<iterator>;
using const_reverse_iterator = std::reverse_iterator<const_iterator>;
using node_type            = unspecified;

```

```

// 24.4.7.2, construct/copy/destroy
multiset() : multiset(Compare()) { }
explicit multiset(const Compare& comp, const Allocator& = Allocator());

}

```

24.4.7.2 Constructors [multiset.cons]

```
explicit multiset(const Compare& comp, const Allocator& = Allocator());
```

Effects: Constructs an empty multiset using the specified comparison object and allocator.

Complexity: Constant.

```
template<class InputIterator>
multiset(InputIterator first, InputIterator last,
        const Compare& comp = Compare(), const Allocator& = Allocator());
```

Effects: Constructs an empty multiset using the specified comparison object and allocator, and inserts elements from the range [first, last).

Complexity: Linear in N if the range [first, last) is already sorted with respect to comp and otherwise $N \log N$, where N is last - first.

```
template<container-compatible-range<value_type> R>
multiset(from_range_t, R&& rg, const Compare& comp = Compare(), const Allocator& = Allocator());
```

Effects: Constructs an empty multiset using the specified comparison object and allocator, and inserts elements from the range rg.

Complexity: Linear in N if `rg` is already sorted with respect to `comp` and otherwise $N \log N$, where N is `ranges::distance(rg)`.

24.4.7.3 Erasure

[multiset.erasure]

```
template<class Key, class Compare, class Allocator, class Predicate>
typename multiset<Key, Compare, Allocator>::size_type
erase_if(multiset<Key, Compare, Allocator>& c, Predicate pred);
```

Effects: Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
return original_size - c.size();
```

24.5 Unordered associative containers

[unord]

24.5.1 General

[unord.general]

The header `<unordered_map>` defines the class templates `unordered_map` and `unordered_multimap`; the header `<unordered_set>` defines the class templates `unordered_set` and `unordered_multiset`.

The exposition-only alias templates *iter-value-type*, *iter-key-type*, *iter-mapped-type*, *iter-to-alloc-type*, *range-key-type*, *range-mapped-type*, and *range-to-alloc-type* defined in 24.4.1 may appear in deduction guides for unordered containers.

24.5.2 Header `<unordered_map>` synopsis

[unord.map.syn]

```
#include <compare> // see 17.11.1
#include <initializer_list> // see 17.10.2

namespace std {
    // 24.5.4, class template unordered_map
    template<class Key,
             class T,
             class Hash = hash<Key>,
             class Pred = equal_to<Key>,
             class Alloc = allocator<pair<const Key, T>>>
    class unordered_map;

    // 24.5.5, class template unordered_multimap

}

```

24.5.4 Class template `unordered_map`

[unord.map]

24.5.4.1 Overview

[unord.map.overview]

An `unordered_map` is an unordered associative container that supports unique keys (an `unordered_map` contains at most one of each key-value) and that associates values of another type `mapped_type` with the keys. The `unordered_map` class supports forward iterators.

An `unordered_map` meets all of the requirements of a container (24.2.2.2), of an allocator-aware container (24.2.2.5), and of an unordered associative container (24.2.8). It provides the operations described in the preceding requirements table for unique keys; that is, an `unordered_map` supports the `a_uniq` operations in that table, not the `a_eq` operations. For an `unordered_map<Key, T>` the `key_type` is `Key`, the `mapped_type` is `T`, and the `value_type` is `pair<const Key, T>`.

Subclause 24.5.4 only describes operations on `unordered_map` that are not described in one of the requirement tables, or for which there is additional semantic information.

```

namespace std {
    template<class Key,
              class T,
              class Hash = hash<Key>,
              class Pred = equal_to<Key>,
              class Allocator = allocator<pair<const Key, T>>>
    class unordered_map {
    public:
        // types
        using key_type           = Key;
        using mapped_type        = T;
        using value_type          = pair<const Key, T>;
        using hasher              = Hash;
        using key_equal           = Pred;
    };
}

```

```

             equal_to<iter-key-type<InputIterator>>, Allocator>;

template<ranges::input_range R, class Allocator>
unordered_map(from_range_t, R&&, typename see below::size_type, Allocator)
-> unordered_map<range-key-type<R>, range-mapped-type<R>, hash<range-key-type<R>>,
             equal_to<range-key-type<R>>, Allocator>;

template<ranges::input_range R, class Allocator>
unordered_map(from_range_t, R&&, Allocator)
-> unordered_map<range-key-type<R>, range-mapped-type<R>, hash<range-key-type<R>>,
             equal_to<range-key-type<R>>, Allocator>;

template<ranges::input_range R, class Hash, class Allocator>
unordered_map(from_range_t, R&&, typename see below::size_type, Hash, Allocator)
-> unordered_map<range-key-type<R>, range-mapped-type<R>, Hash,
             equal_to<range-key-type<R>>, Allocator>;

template<class Key, class T, class Allocator>
unordered_map(initializer_list<pair<Key, T>>, typename see below::size_type,
             Allocator)
-> unordered_map<Key, T, hash<Key>, equal_to<Key>, Allocator>;

template<class Key, class T, class Allocator>
unordered_map(initializer_list<pair<Key, T>>, Allocator)
-> unordered_map<Key, T, hash<Key>, equal_to<Key>, Allocator>;

```

```

template<class Key, class T, class Hash, class Allocator>
    unordered_map(initializer_list<pair<Key, T>>, typename see below::size_type, Hash,
                  Allocator)
    -> unordered_map<Key, T, Hash, equal_to<Key>, Allocator>;
}

```

A `size_type` parameter type in an `unordered_map` deduction guide refers to the `size_type` member type of the type deduced by the deduction guide.

24.5.4.2 Constructors

[unord.map.cnstr]

```

unordered_map() : unordered_map(size_type(see below)) { }
explicit unordered_map(size_type n,
                      const hasher& hf = hasher(),
                      const key_equal& eql = key_equal(),
                      const allocator_type& a = allocator_type());

```

Effects: Constructs an empty `unordered_map` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. For the default constructor, the number of buckets is implementation-defined. `max_load_factor()` returns 1.0.

Complexity: Constant.

```

template<class InputIterator>
    unordered_map(InputIterator f, InputIterator l,
                  size_type n = see below,
                  const hasher& hf = hasher(),
                  const key_equal& eql = key_equal(),
                  const allocator_type& a = allocator_type());
template<container-compatible-range<value_type> R>
    unordered_map(from_range_t, R&& rg,
                  size_type n = see below,
                  const hasher& hf = hasher(),
                  const key_equal& eql = key_equal(),
                  const allocator_type& a = allocator_type());
unordered_map(initializer_list<value_type> il,
              size_type n = see below,
              const hasher& hf = hasher(),
              const key_equal& eql = key_equal(),
              const allocator_type& a = allocator_type());

```

Effects: Constructs an empty `unordered_map` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. If `n` is not provided, the number of buckets is implementation-defined. Then inserts elements from the range `[f, l)`, `rg`, or `il`, respectively. `max_load_factor()` returns 1.0.

Complexity: Average case linear, worst case quadratic.

24.5.4.3 Element access

[unord.map.elem]

```
mapped_type& operator[](const key_type& k);
```

Effects: Equivalent to: `return try_emplace(k).first->second;`

```
mapped_type& operator[](key_type&& k);
```

Effects: Equivalent to: `return try_emplace(std::move(k)).first->second;`

```
mapped_type& at(const key_type& k);
```

```
const mapped_type& at(const key_type& k) const;
```

Returns: A reference to `x.second`, where `x` is the (unique) element whose key is equivalent to `k`.

Throws: An exception object of type `out_of_range` if no such element is present.

24.5.4.4 Modifiers

[unord.map.modifiers]

```

template<class P>
    pair<iterator, bool> insert(P&& obj);

```

Constraints: `is_constructible_v<value_type, P&&>` is true.

Effects: Equivalent to: `return emplace(std::forward<P>(obj));`

```
template<class P>
    iterator insert(const_iterator hint, P&& obj);
```

Constraints: `is_constructible_v<value_type, P&&>` is true.

Effects: Equivalent to: `return emplace_hint(hint, std::forward<P>(obj));`

```
template<class... Args>
    pair<iterator, bool> try_emplace(const key_type& k, Args&&... args);
template<class... Args>
    iterator try_emplace(const_iterator hint, const key_type& k, Args&&... args);
```

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into `unordered_map` from `piecewise_construct`, `forward_as_tuple(k)`, `forward_as_tuple(std::forward<Args>(args)...)...`.

Effects: If the map already contains an element whose key is equivalent to `k`, there is no effect. Otherwise inserts an object of type `value_type` constructed with `piecewise_construct`, `forward_as_tuple(k)`, `forward_as_tuple(std::forward<Args>(args)...)...`.

Returns: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

Complexity: The same as `emplace` and `emplace_hint`, respectively.

```
template<class... Args>
    pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);
template<class... Args>
    iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);
```

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into `unordered_map` from `piecewise_construct`, `forward_as_tuple(std::move(k))`, `forward_as_tuple(std::forward<Args>(args)...)...`.

Effects: If the map already contains an element whose key is equivalent to `k`, there is no effect. Otherwise inserts an object of type `value_type` constructed with `piecewise_construct`, `forward_as_tuple(std::move(k))`, `forward_as_tuple(std::forward<Args>(args)...)...`.

Returns: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

Complexity: The same as `emplace` and `emplace_hint`, respectively.

```
template<class M>
    pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);
template<class M>
    iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);
```

Mandates: `is_assignable_v<mapped_type&, M&&>` is true.

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into `unordered_map` from `k`, `std::forward<M>(obj)`.

Effects: If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::forward<M>(obj)` to `e.second`. Otherwise inserts an object of type `value_type` constructed with `k`, `std::forward<M>(obj)`.

Returns: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

Complexity: The same as `emplace` and `emplace_hint`, respectively.

```
template<class M>
    pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);
template<class M>
    iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);
```

Mandates: `is_assignable_v<mapped_type&, M&&>` is true.

Preconditions: `value_type` is *Cpp17EmplaceConstructible* into `unordered_map` from `std::move(k)`, `std::forward<M>(obj)`.

Effects: If the map already contains an element *e* whose key is equivalent to *k*, assigns `std::forward<M>(obj)` to *e*.second. Otherwise inserts an object of type `value_type` constructed with `std::move(k)`, `std::forward<M>(obj)`.

Returns: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to *k*.

Complexity: The same as `emplace` and `emplace_hint`, respectively.

24.5.4.5 Erasure

[unord.map.erase]

```
template<class K, class T, class H, class P, class A, class Predicate>
typename unordered_map<K, T, H, P, A>::size_type
erase_if(unordered_map<K, T, H, P, A>& c, Predicate pred);
```

Effects: Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
return original_size - c.size();
```

24.5.5 Class template `unordered_multimap`

[unord.multimap]

24.5.5.1 Overview

[unord.multimap.overview]

An `unordered_multimap` is an unordered associative container that supports equivalent keys (an instance of `unordered_multimap` may contain multiple copies of each key value) and that associates values of another type `mapped_type` with the keys. The `unordered_multimap` class supports forward iterators.

An `unordered_multimap` meets all of the requirements of a container (24.2.2.2), of an allocator-aware container (24.2.2.5), and of an unordered associative container (24.2.8). It provides the operations described in the preceding requirements table for equivalent keys; that is, an `unordered_multimap` supports the `a_eq` operations in that table, not the `a_uniq` operations. For an `unordered_multimap<Key, T>` the `key_type` is `Key`, the `mapped_type` is `T`, and the `value_type` is `pair<const Key, T>`.

Subclause 24.5.5 only describes operations on `unordered_multimap` that are not described in one of the requirement tables, or for which there is additional semantic information.

```
namespace std {
    template<class Key,
            class T,
            class Hash = hash<Key>,
            class Pred = equal_to<Key>,
            class Allocator = allocator<pair<const Key, T>>>
    class unordered_multimap {
    public:
        // types
        using key_type           = Key;
        using mapped_type       = T;
        using value_type        = pair<const Key, T>;
        using hasher            = Hash;
        using key_equal         = Pred;
        using allocator_type    = Allocator;
        using pointer           = typename allocator_traits<Allocator>::pointer;
        using const_pointer     = typename allocator_traits<Allocator>::const_pointer;
        using reference         = value_type&;
        using const_reference   = const value_type&;
        using size_type         = implementation-defined; // see 24.2
        using difference_type   = implementation-defined; // see 24.2

        using iterator         = implementation-defined; // see 24.2
        using const_iterator   = implementation-defined; // see 24.2
    };
```

```

using local_iterator      = implementation-defined; // see 24.2
using const_local_iterator = implementation-defined; // see 24.2
using node_type           = unspecified;

}

```

A `size_type` parameter type in an `unordered_multimap` deduction guide refers to the `size_type` member type of the type deduced by the deduction guide.

24.5.5.2 Constructors

[unord.multimap.cnstr]

```

unordered_multimap() : unordered_multimap(size_type(see below)) { }
explicit unordered_multimap(size_type n,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());

```

Effects: Constructs an empty `unordered_multimap` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. For the default constructor, the number of buckets is implementation-defined. `max_load_factor()` returns 1.0.

Complexity: Constant.

```

template<class InputIterator>
unordered_multimap(InputIterator f, InputIterator l,
    size_type n = see below,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());

```

```

template<container-compatible-range<value_type> R>
    unordered_multimap(from_range_t, R&& rg,
        size_type n = see below,
        const hasher& hf = hasher(),
        const key_equal& eql = key_equal(),
        const allocator_type& a = allocator_type());
unordered_multimap(initializer_list<value_type> il,
    size_type n = see below,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());

```

Effects: Constructs an empty `unordered_multimap` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. If `n` is not provided, the number of buckets is implementation-defined. Then inserts elements from the range `[f, l)`, `rg`, or `il`, respectively. `max_load_factor()` returns 1.0.

Complexity: Average case linear, worst case quadratic.

24.5.5.3 Modifiers

[unord.multimap.modifiers]

```

template<class P>
    iterator insert(P&& obj);

```

Constraints: `is_constructible_v<value_type, P&&>` is true.

Effects: Equivalent to: `return emplace(std::forward<P>(obj));`

```

template<class P>
    iterator insert(const_iterator hint, P&& obj);

```

Constraints: `is_constructible_v<value_type, P&&>` is true.

Effects: Equivalent to: `return emplace_hint(hint, std::forward<P>(obj));`

24.5.5.4 Erasure

[unord.multimap.erase]

```

template<class K, class T, class H, class P, class A, class Predicate>
    typename unordered_multimap<K, T, H, P, A>::size_type
    erase_if(unordered_multimap<K, T, H, P, A>& c, Predicate pred);

```

Effects: Equivalent to:

```

auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
return original_size - c.size();

```

24.5.6 Class template `unordered_set`

[unord.set]

24.5.6.1 Overview

[unord.set.overview]

An `unordered_set` is an unordered associative container that supports unique keys (an `unordered_set` contains at most one of each key value) and in which the elements' keys are the elements themselves. The `unordered_set` class supports forward iterators.

An `unordered_set` meets all of the requirements of a container (24.2.2.2), of an allocator-aware container (24.2.2.5), of an unordered associative container (24.2.8). It provides the operations described in the preceding requirements table for unique keys; that is, an `unordered_set` supports the `a_uniq` operations in that table, not the `a_eq` operations. For an `unordered_set<Key>` the `key_type` and the `value_type` are both `Key`. The `iterator` and `const_iterator` types are both constant iterator types. It is unspecified whether they are the same type.

Subclause 24.5.6 only describes operations on `unordered_set` that are not described in one of the requirement tables, or for which there is additional semantic information.

```

namespace std {
    template<class Key,
            class Hash = hash<Key>,
            class Pred = equal_to<Key>,
            class Allocator = allocator<Key>>
    class unordered_set {
    public:
        // types
        using key_type          = Key;
        using value_type        = Key;
        using hasher            = Hash;
        using key_equal         = Pred;
        using allocator_type    = Allocator;
        using pointer           = typename allocator_traits<Allocator>::pointer;
        using const_pointer     = typename allocator_traits<Allocator>::const_pointer;
        using reference         = value_type&;
        using const_reference   = const value_type&;
        using size_type         = implementation-defined; // see 24.2

```

A `size_type` parameter type in an `unordered_set` deduction guide refers to the `size_type` member type of the type deduced by the deduction guide.

24.5.6.2 Constructors

[unord.set.cnstr]

```

unordered_set() : unordered_set(size_type(see below)) { }
explicit unordered_set(size_type n,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());

```

Effects: Constructs an empty `unordered_set` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. For the default constructor, the number of buckets is

implementation-defined. `max_load_factor()` returns 1.0.

Complexity: Constant.

```
template<class InputIterator>
    unordered_set(InputIterator f, InputIterator l,
                  size_type n = see below,
                  const hasher& hf = hasher(),
                  const key_equal& eql = key_equal(),
                  const allocator_type& a = allocator_type());
template<container-compatible-range<value_type> R>
    unordered_multiset(from_range_t, R&& rg,
                      size_type n = see below,
                      const hasher& hf = hasher(),
                      const key_equal& eql = key_equal(),
                      const allocator_type& a = allocator_type());
unordered_set(initializer_list<value_type> il,
              size_type n = see below,
              const hasher& hf = hasher(),
              const key_equal& eql = key_equal(),
              const allocator_type& a = allocator_type());
```

Effects: Constructs an empty `unordered_set` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. If `n` is not provided, the number of buckets is implementation-defined. Then inserts elements from the range `[f,l)`, `rg`, or `il`, respectively. `max_load_factor()` returns 1.0.

Complexity: Average case linear, worst case quadratic.

24.5.6.3 Erasure

[unord.set.erasure]

```
template<class K, class H, class P, class A, class Predicate>
    typename unordered_set<K, H, P, A>::size_type
    erase_if(unordered_set<K, H, P, A>& c, Predicate pred);
```

Effects: Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
return original_size - c.size();
```

24.5.7 Class template `unordered_multiset`

[unord.multiset]

24.5.7.1 Overview

[unord.multiset.overview]

An `unordered_multiset` is an unordered associative container that supports equivalent keys (an instance of `unordered_multiset` may contain multiple copies of the same key value) and in which each element's key is the element itself. The `unordered_multiset` class supports forward iterators.

An `unordered_multiset` meets all of the requirements of a container (24.2.2.2), of an allocator-aware container (24.2.2.5), and of an unordered associative container (24.2.8). It provides the operations described in the preceding requirements table for equivalent keys; that is, an `unordered_multiset` supports the `a_eq` operations in that table, not the `a_uniq` operations. For an `unordered_multiset<Key>` the `key_type` and the `value_type` are both `Key`. The `iterator` and `const_iterator` types are both constant iterator types. It is unspecified whether they are the same type.

Subclause 24.5.7 only describes operations on `unordered_multiset` that are not described in one of the requirement tables, or for which there is additional semantic information.

```

namespace std {
    template<class Key,
            class Hash = hash<Key>,
            class Pred = equal_to<Key>,
            class Allocator = allocator<Key>>
    class unordered_multiset {
    public:
        // types
        using key_type          = Key;
        using value_type        = Key;
        using hasher            = Hash;
        using key_equal         = Pred;
        using allocator_type    = Allocator;
        using pointer           = typename allocator_traits<Allocator>::pointer;
        using const_pointer     = typename allocator_traits<Allocator>::const_pointer;
        using reference         = value_type&;
        using const_reference   = const value_type&;
        using size_type         = implementation-defined; // see 24.2
        using difference_type   = implementation-defined; // see 24.2

unordered_multiset(initializer_list<T>, typename see below::size_type, Hash, Allocator)
-> unordered_multiset<T, Hash, equal_to<T>, Allocator>;
}

```

A `size_type` parameter type in an `unordered_multiset` deduction guide refers to the `size_type` member type of the type deduced by the deduction guide.

24.5.7.2 Constructors

[unord.multiset.cnstr]

```

unordered_multiset() : unordered_multiset(size_type(see below)) { }
explicit unordered_multiset(size_type n,
                           const hasher& hf = hasher(),
                           const key_equal& eql = key_equal(),
                           const allocator_type& a = allocator_type());

```

Effects: Constructs an empty `unordered_multiset` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. For the default constructor, the number of

buckets is implementation-defined. `max_load_factor()` returns 1.0.

Complexity: Constant.

```
template<class InputIterator>
    unordered_multiset(InputIterator f, InputIterator l,
                      size_type n = see below,
                      const hasher& hf = hasher(),
                      const key_equal& eql = key_equal(),
                      const allocator_type& a = allocator_type());
template<container-compatible-range<value_type> R>
    unordered_multiset(from_range_t, R&& rg,
                      size_type n = see below,
                      const hasher& hf = hasher(),
                      const key_equal& eql = key_equal(),
                      const allocator_type& a = allocator_type());
unordered_multiset(initializer_list<value_type> il,
                  size_type n = see below,
                  const hasher& hf = hasher(),
                  const key_equal& eql = key_equal(),
                  const allocator_type& a = allocator_type());
```

Effects: Constructs an empty `unordered_multiset` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. If `n` is not provided, the number of buckets is implementation-defined. Then inserts elements from the range `[f, l)`, `rg`, or `il`, respectively. `max_load_factor()` returns 1.0.

Complexity: Average case linear, worst case quadratic.

24.5.7.3 Erasure

[unord.multiset.erasure]

```
template<class K, class H, class P, class A, class Predicate>
    typename unordered_multiset<K, H, P, A>::size_type
    erase_if(unordered_multiset<K, H, P, A>& c, Predicate pred);
```

Effects: Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
return original_size - c.size();
```

24.6 Container adaptors

[container.adaptors]

24.6.1 General

[container.adaptors.general]

The headers `<queue>`, `<stack>`, `<flat_map>`, and `<flat_set>` define the container adaptors `queue` and `priority_queue`, `stack`, `flat_map` and `flat_multimap`, and `flat_set` and `flat_multiset`, respectively.

Each container adaptor takes one or more template parameters named `Container`, `KeyContainer`, or `MappedContainer` that denote the types of containers that the container adaptor adapts. Each container adaptor has at least one constructor that takes a reference argument to one or more such template parameters. For each constructor reference argument to a container `C`, the constructor copies the container into the container adaptor. If `C` takes an allocator, then a compatible allocator may be passed in to the adaptor's constructor. Otherwise, normal copy or move construction is used for the container argument. For the container adaptors that take a single container template parameter `Container`, the first template parameter `T` of the container adaptor shall denote the same type as `Container::value_type`.

For container adaptors, no `swap` function throws an exception unless that exception is thrown by the swap of the adaptor's `Container`, `KeyContainer`, `MappedContainer`, or `Compare` object (if any).

A constructor template of a container adaptor shall not participate in overload resolution if it has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter.

For container adaptors that have them, the `insert`, `emplace`, and `erase` members affect the validity of iterators, references, and pointers to the adaptor's container(s) in the same way that the containers' respective `insert`, `emplace`, and `erase` members do.

EXAMPLE A call to `flat_map<Key, T>::insert` can invalidate all iterators to the `flat_map`.

A deduction guide for a container adaptor shall not participate in overload resolution if any of the following are true:

- It has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter.
- It has a `Compare` template parameter and a type that qualifies as an allocator is deduced for that parameter.
- It has a `Container`, `KeyContainer`, or `MappedContainer` template parameter and a type that qualifies as an allocator is deduced for that parameter.
- It has no `Container`, `KeyContainer`, or `MappedContainer` template parameter, and it has an `Allocator` template parameter, and a type that does not qualify as an allocator is deduced for that parameter.
- It has both `Container` and `Allocator` template parameters, and `uses_allocator_v<Container, Allocator>` is false.
- It has both `KeyContainer` and `Allocator` template parameters, and `uses_allocator_v<KeyContainer, Allocator>` is false.
- It has both `KeyContainer` and `Compare` template parameters, and

```
is_invocable_v<const Compare&,
               const typename KeyContainer::value_type&,
               const typename KeyContainer::value_type&>
```

 is not a valid expression or is false.
- It has both `MappedContainer` and `Allocator` template parameters, and `uses_allocator_v<MappedContainer, Allocator>` is false.

The exposition-only alias template *iter-value-type* defined in 24.3.1 and the exposition-only alias templates *iter-key-type*, *iter-mapped-type*, *range-key-type*, and *range-mapped-type* defined in 24.4.1 may appear in deduction guides for container adaptors.

The following exposition-only alias template may appear in deduction guides for container adaptors:

```
template<class Allocator, class T>
using alloc-rebind = // exposition only
    typename allocator_traits<Allocator>::template rebind_alloc<T>;
```

24.6.2 Header <queue> synopsis

}
```

24.6.6 Class template queue

[queue]

24.6.6.1 Definition

[queue.defn]

Any sequence container supporting operations `front()`, `back()`, `push_back()` and `pop_front()` can be used to instantiate `queue`. In particular, `list` (24.3.10) and `deque` (24.3.8) can be used.

```
namespace std {
    template<class T, class Container = deque<T>>
    class queue {
    public:
        using value_type      = typename Container::value_type;

}
```

```

template<ranges::input_range R>
    queue(from_range_t, R&&) -> queue<ranges::range_value_t<R>>;

template<class Container, class Allocator>
    queue(Container, Allocator) -> queue<typename Container::value_type, Container>;

template<class InputIterator, class Allocator>
    queue(InputIterator, InputIterator, Allocator)
        -> queue<iter_value_type<InputIterator>, deque<iter_value_type<InputIterator>,
            Allocator>>;

template<ranges::input_range R, class Allocator>
    queue(from_range_t, R&&, Allocator)
        -> queue<ranges::range_value_t<R>, deque<ranges::range_value_t<R>, Allocator>>;

template<class T, class Container, class Alloc>
    struct uses_allocator<queue<T, Container>, Alloc>
        : uses_allocator<Container, Alloc>::type { };
}

```

24.6.6.2 Constructors

[queue.cons]

```
explicit queue(const Container& cont);
```

Effects: Initializes *c* with *cont*.

```
explicit queue(Container&& cont);
```

Effects: Initializes *c* with `std::move(cont)`.

```
template<class InputIterator>
    queue(InputIterator first, InputIterator last);
```

Effects: Initializes *c* with *first* as the first argument and *last* as the second argument.

```
template<container_compatible_range<T> R>
    queue(from_range_t, R&& rg);
```

Effects: Initializes *c* with `ranges::to<Container>(std::forward<R>(rg))`.

24.6.6.3 Constructors with allocators

[queue.cons.alloc]

If `uses_allocator_v<container_type, Alloc>` is false the constructors in this subclause shall not participate in overload resolution.

```
template<class Alloc> explicit queue(const Alloc& a);
```

Effects: Initializes *c* with *a*.

```
template<class Alloc> queue(const container_type& cont, const Alloc& a);
```

Effects: Initializes *c* with *cont* as the first argument and *a* as the second argument.

```
template<class Alloc> queue(container_type&& cont, const Alloc& a);
```

Effects: Initializes *c* with `std::move(cont)` as the first argument and *a* as the second argument.

```
template<class Alloc> queue(const queue& q, const Alloc& a);
```

Effects: Initializes *c* with *q.c* as the first argument and *a* as the second argument.

```
template<class Alloc> queue(queue&& q, const Alloc& a);
```

Effects: Initializes *c* with `std::move(q.c)` as the first argument and *a* as the second argument.

```
template<class InputIterator, class Alloc>
    queue(InputIterator first, InputIterator last, const Alloc& alloc);
```

Effects: Initializes *c* with *first* as the first argument, *last* as the second argument, and *alloc* as the third argument.

```
template<container-compatible-range<T> R, class Alloc>
queue(from_range_t, R&& rg, const Alloc& a);
```

Effects: Initializes `c` with `ranges::to<Container>(std::forward<R>(rg), a)`.

24.6.6.4 Modifiers

[queue.mod]

```
template<container-compatible-range<T> R>
void push_range(R&& rg);
```

Effects: Equivalent to `c.append_range(std::forward<R>(rg))` if that is a valid expression, otherwise `ranges::copy(rg, back_inserter(c))`.

24.6.6.5 Operators

[queue.ops]

```
template<class T, class Container>
bool operator==(const queue<T, Container>& x, const queue<T, Container>& y);
```

Returns: `x.c == y.c`.

```
template<class T, class Container>
bool operator!=(const queue<T, Container>& x, const queue<T, Container>& y);
```

Returns: `x.c != y.c`.

```
template<class T, class Container>
bool operator< (const queue<T, Container>& x, const queue<T, Container>& y);
```

Returns: `x.c < y.c`.

```
template<class T, class Container>
bool operator> (const queue<T, Container>& x, const queue<T, Container>& y);
```

Returns: `x.c > y.c`.

```
template<class T, class Container>
bool operator<= (const queue<T, Container>& x, const queue<T, Container>& y);
```

Returns: `x.c <= y.c`.

```
template<class T, class Container>
bool operator>= (const queue<T, Container>& x,
                const queue<T, Container>& y);
```

Returns: `x.c >= y.c`.

```
template<class T, three_way_comparable Container>
compare_three_way_result_t<Container>
operator<=>(const queue<T, Container>& x, const queue<T, Container>& y);
```

Returns: `x.c <=> y.c`.

24.6.6.6 Specialized algorithms

[queue.special]

```
template<class T, class Container>
void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));
```

Constraints: `is_swappable_v<Container>` is true.

Effects: As if by `x.swap(y)`.

24.6.7 Class template `priority_queue`

[priority.queue]

24.6.7.1 Overview

[priorityqueue.overview]

Any sequence container with random access iterator and supporting operations `front()`, `push_back()` and `pop_back()` can be used to instantiate `priority_queue`. In particular, `vector` (24.3.11) and `deque` (24.3.8) can be used. Instantiating `priority_queue` also involves supplying a function or function object for making priority comparisons; the library assumes that the function or function object defines a strict weak ordering (27.8).

```

namespace std {
    template<class T, class Container = vector<T>,
            class Compare = less<typename Container::value_type>>
    class priority_queue {
    public:
        using value_type      = typename Container::value_type;
        using reference       = typename Container::reference;
        using const_reference = typename Container::const_reference;
        using size_type       = typename Container::size_type;
        using container_type   = Container;
        using value_compare    = Compare;

    protected:
        Container c;
        Compare comp;

    public:
        priority_queue() : priority_queue(Compare()) {}
        explicit priority_queue(const Compare& x) : priority_queue(x, Container()) {}
        priority_queue(const Compare& x, const Container&);
        priority_queue(const Compare& x, Container&&);
        template<class InputIterator>
            priority_queue(InputIterator first, InputIterator last, const Compare& x = Compare());
        template<class InputIterator>
            priority_queue(InputIterator first, InputIterator last, const Compare& x,
                           const Container&);
        template<class InputIterator>
            priority_queue(InputIterator first, InputIterator last, const Compare& x,
                           Container&&);
        template<container-compatible-range<T> R>
            priority_queue(from_range_t, R&& rg, const Compare& x = Compare());
        template<class Alloc> explicit priority_queue(const Alloc&);
        template<class Alloc> priority_queue(const Compare&, const Alloc&);
        template<class Alloc> priority_queue(const Compare&, const Container&, const Alloc&);
        template<class Alloc> priority_queue(const Compare&, Container&&, const Alloc&);
        template<class Alloc> priority_queue(const priority_queue&, const Alloc&);
        template<class Alloc> priority_queue(priority_queue&&, const Alloc&);
        template<class InputIterator, class Alloc>

// no equality is provided

template<class T, class Container, class Compare, class Alloc>
struct uses_allocator<priority_queue<T, Container, Compare>, Alloc>
: uses_allocator<Container, Alloc>::type { };
}

```

24.6.7.2 Constructors

[priority_queue.cons]

```

priority_queue(const Compare& x, const Container& y);
priority_queue(const Compare& x, Container&& y);

```

Preconditions: x defines a strict weak ordering (27.8).

Effects: Initializes comp with x and c with y (copy constructing or move constructing as appropriate); calls make_heap(c.begin(), c.end(), comp).

```

template<class InputIterator>
priority_queue(InputIterator first, InputIterator last, const Compare& x = Compare());

```

Preconditions: x defines a strict weak ordering (27.8).

Effects: Initializes c with first as the first argument and last as the second argument, and initializes comp with x; then calls make_heap(c.begin(), c.end(), comp).

```
template<class InputIterator>
priority_queue(InputIterator first, InputIterator last, const Compare& x, const Container& y);
template<class InputIterator>
priority_queue(InputIterator first, InputIterator last, const Compare& x, Container&& y);
```

Preconditions: `x` defines a strict weak ordering (27.8).

Effects: Initializes `comp` with `x` and `c` with `y` (copy constructing or move constructing as appropriate); calls `c.insert(c.end(), first, last)`; and finally calls `make_heap(c.begin(), c.end(), comp)`.

```
template<container-compatible-range<T> R>
priority_queue(from_range_t, R&& rg, const Compare& x = Compare());
```

Preconditions: `x` defines a strict weak ordering (27.8).

Effects: Initializes `comp` with `x` and `c` with `ranges::to<Container>(std::forward<R>(rg))` and finally calls `make_heap(c.begin(), c.end(), comp)`.

24.6.7.3 Constructors with allocators

[priority_queue.cons.alloc]

If `uses_allocator_v<container_type, Alloc>` is false the constructors in this subclause shall not participate in overload resolution.

```
template<class Alloc> explicit priority_queue(const Alloc& a);
```

Effects: Initializes `c` with `a` and value-initializes `comp`.

```
template<class Alloc> priority_queue(const Compare& compare, const Alloc& a);
```

Effects: Initializes `c` with `a` and initializes `comp` with `compare`.

```
template<class Alloc>
priority_queue(const Compare& compare, const Container& cont, const Alloc& a);
```

Effects: Initializes `c` with `cont` as the first argument and `a` as the second argument, and initializes `comp` with `compare`; calls `make_heap(c.begin(), c.end(), comp)`.

```
template<class Alloc>
priority_queue(const Compare& compare, Container&& cont, const Alloc& a);
```

Effects: Initializes `c` with `std::move(cont)` as the first argument and `a` as the second argument, and initializes `comp` with `compare`; calls `make_heap(c.begin(), c.end(), comp)`.

```
template<class Alloc> priority_queue(const priority_queue& q, const Alloc& a);
```

Effects: Initializes `c` with `q.c` as the first argument and `a` as the second argument, and initializes `comp` with `q.comp`.

```
template<class Alloc> priority_queue(priority_queue&& q, const Alloc& a);
```

Effects: Initializes `c` with `std::move(q.c)` as the first argument and `a` as the second argument, and initializes `comp` with `std::move(q.comp)`.

```
template<class InputIterator, class Alloc>
priority_queue(InputIterator first, InputIterator last, const Alloc& a);
```

Effects: Initializes `c` with `first` as the first argument, `last` as the second argument, and `a` as the third argument, and value-initializes `comp`; calls `make_heap(c.begin(), c.end(), comp)`.

```
template<class InputIterator, class Alloc>
priority_queue(InputIterator first, InputIterator last, const Compare& compare, const Alloc& a);
```

Effects: Initializes `c` with `first` as the first argument, `last` as the second argument, and `a` as the third argument, and initializes `comp` with `compare`; calls `make_heap(c.begin(), c.end(), comp)`.

```
template<class InputIterator, class Alloc>
priority_queue(InputIterator first, InputIterator last, const Compare& compare,
               const Container& cont, const Alloc& a);
```

Effects: Initializes `c` with `cont` as the first argument and `a` as the second argument, and initializes `comp` with `compare`; calls `c.insert(c.end(), first, last)`; and finally calls `make_heap(c.begin(), c.end(), comp)`.

```
template<class InputIterator, class Alloc>
priority_queue(InputIterator first, InputIterator last, const Compare& compare, Container&& cont,
               const Alloc& a);
```

Effects: Initializes `c` with `std::move(cont)` as the first argument and `a` as the second argument, and initializes `comp` with `compare`; calls `c.insert(c.end(), first, last)`; and finally calls `make_heap(c.begin(), c.end(), comp)`.

```
template<container-compatible-range<T> R, class Alloc>
priority_queue(from_range_t, R&& rg, const Compare& compare, const Alloc& a);
```

Effects: Initializes `comp` with `compare` and `c` with `ranges::to<Container>(std::forward<R>(rg), a)`; calls `make_heap(c.begin(), c.end(), comp)`.

```
template<container-compatible-range<T> R, class Alloc>
priority_queue(from_range_t, R&& rg, const Alloc& a);
```

Effects: Initializes `c` with `ranges::to<Container>(std::forward<R>(rg), a)`; calls `make_heap(c.begin(), c.end(), comp)`.

24.6.7.4 Members

[priorityqueue.members]

```
void push(const value_type& x);
```

Effects: As if by:

```
c.push_back(x);
push_heap(c.begin(), c.end(), comp);
```

```
void push(value_type&& x);
```

Effects: As if by:

```
c.push_back(std::move(x));
push_heap(c.begin(), c.end(), comp);
```

```
template<container-compatible-range<T> R>
void push_range(R&& rg);
```

Effects: Inserts all elements of `rg` in `c` via `c.append_range(std::forward<R>(rg))` if that is a valid expression, or `ranges::copy(rg, back_inserter(c))` otherwise. Then restores the heap property as if by `make_heap(c.begin(), c.end(), comp)`.

Postconditions: `is_heap(c.begin(), c.end(), comp)` is true.

```
template<class... Args> void emplace(Args&&... args);
```

Effects: As if by:

```
c.emplace_back(std::forward<Args>(args)...);
push_heap(c.begin(), c.end(), comp);
```

```
void pop();
```

Effects: As if by:

```
pop_heap(c.begin(), c.end(), comp);
c.pop_back();
```

24.6.7.5 Specialized algorithms

[priorityqueue.special]

```
template<class T, class Container, class Compare>
void swap(priority_queue<T, Container, Compare>& x,
          priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));
```

Constraints: `is_swappable_v<Container>` is true and `is_swappable_v<Compare>` is true.

Effects: As if by `x.swap(y)`.

24.6.8 Class template stack

[stack]

24.6.8.1 General

[stack.general]

Any sequence container supporting operations `back()`, `push_back()` and `pop_back()` can be used to instantiate `stack`. In particular, `vector` (24.3.11), `list` (24.3.10) and `deque` (24.3.8) can be used.

24.6.8.2 Definition

[stack.defn]

```

namespace std {
    template<class T, class Container = deque<T>>
    class stack {
    public:

template<class T, class Container, class Alloc>
    struct uses_allocator<stack<T, Container>, Alloc>
        : uses_allocator<Container, Alloc>::type { };
}

```

24.6.8.3 Constructors

[stack.cons]

```
explicit stack(const Container& cont);
```

Effects: Initializes *c* with *cont*.

```
explicit stack(Container&& cont);
```

Effects: Initializes *c* with `std::move(cont)`.

```
template<class InputIterator>
    stack(InputIterator first, InputIterator last);
```

Effects: Initializes *c* with *first* as the first argument and *last* as the second argument.

```
template<container-compatible-range<T> R>
    stack(from_range_t, R&& rg);
```

Effects: Initializes *c* with `ranges::to<Container>(std::forward<R>(rg))`.

24.6.8.4 Constructors with allocators

[stack.cons.alloc]

If `uses_allocator_v<container_type, Alloc>` is false the constructors in this subclause shall not participate in overload resolution.

```
template<class Alloc> explicit stack(const Alloc& a);
```

Effects: Initializes *c* with *a*.

```
template<class Alloc> stack(const container_type& cont, const Alloc& a);
```

Effects: Initializes *c* with *cont* as the first argument and *a* as the second argument.

```
template<class Alloc> stack(container_type&& cont, const Alloc& a);
```

Effects: Initializes *c* with `std::move(cont)` as the first argument and *a* as the second argument.

```
template<class Alloc> stack(const stack& s, const Alloc& a);
```

Effects: Initializes *c* with *s.c* as the first argument and *a* as the second argument.

```
template<class Alloc> stack(stack&& s, const Alloc& a);
```

Effects: Initializes *c* with `std::move(s.c)` as the first argument and *a* as the second argument.

```
template<class InputIterator, class Alloc>
    stack(InputIterator first, InputIterator last, const Alloc& alloc);
```

Effects: Initializes *c* with *first* as the first argument, *last* as the second argument, and *alloc* as the third argument.

```
template<container-compatible-range<T> R, class Alloc>
    stack(from_range_t, R&& rg, const Alloc& a);
```

Effects: Initializes *c* with `ranges::to<Container>(std::forward<R>(rg), a)`.

24.6.8.5 Modifiers

[stack.mod]

```
template<container-compatible-range<T> R>
    void push_range(R&& rg);
```

Effects: Equivalent to `c.append_range(std::forward<R>(rg))` if that is a valid expression, otherwise `ranges::copy(rg, back_inserter(c))`.

24.6.8.6 Operators

[stack.ops]

```
template<class T, class Container>
bool operator==(const stack<T, Container>& x, const stack<T, Container>& y);
```

Returns: $x.c == y.c$.

```
template<class T, class Container>
bool operator!=(const stack<T, Container>& x, const stack<T, Container>& y);
```

Returns: $x.c != y.c$.

```
template<class T, class Container>
bool operator<(const stack<T, Container>& x, const stack<T, Container>& y);
```

Returns: $x.c < y.c$.

```
template<class T, class Container>
bool operator>(const stack<T, Container>& x, const stack<T, Container>& y);
```

Returns: $x.c > y.c$.

```
template<class T, class Container>
bool operator<=(const stack<T, Container>& x, const stack<T, Container>& y);
```

Returns: $x.c \leq y.c$.

```
template<class T, class Container>
bool operator>=(const stack<T, Container>& x, const stack<T, Container>& y);
```

Returns: $x.c \geq y.c$.

```
template<class T, three_way_comparable Container>
compare_three_way_result_t<Container>
operator<=>(const stack<T, Container>& x, const stack<T, Container>& y);
```

Returns: $x.c \leq y.c$.

24.6.8.7 Specialized algorithms

[stack.special]

```
template<class T, class Container>
void swap(stack<T, Container>& x, stack<T, Container>& y) noexcept(noexcept(x.swap(y)));
```

Constraints: `is_swappable_v<Container>` is true.

Effects: As if by `x.swap(y)`.

24.6.9 Class template `flat_map`

[flat.map]

24.6.9.1 Overview

[flat.map.overview]

A `flat_map` is a container adaptor that provides an associative container interface that supports unique keys (i.e., contains at most one of each key value) and provides for fast retrieval of values of another type `T` based on the keys. `flat_map` supports iterators that meet the *Cpp17InputIterator* requirements and model the `random_access_iterator` concept (25.3.4.13).

A `flat_map` meets all of the requirements of a container (24.2.2.2) and of a reversible container (24.2.2.3), plus the optional container requirements (24.2.2.4). `flat_map` meets the requirements of an associative container (24.2.7), except that:

- it does not meet the requirements related to node handles (24.2.5),
- it does not meet the requirements related to iterator invalidation, and
- the time complexity of the operations that insert or erase a single element from the map is linear, including the ones that take an insertion position iterator.

NOTE 1 A `flat_map` does not meet the additional requirements of an allocator-aware container (24.2.2.5).

A `flat_map` also provides most operations described in 24.2.7 for unique keys. This means that a `flat_map` supports the `a_uniq` operations in 24.2.7 but not the `a_eq` operations. For a `flat_map<Key, T>` the `key_type` is `Key` and the `value_type` is `pair<Key, T>`.

Descriptions are provided here only for operations on `flat_map` that are not described in one of those sets of requirements or for operations where there is additional semantic information.

A `flat_map` maintains the following invariants:

- it contains the same number of keys and values;
- the keys are sorted with respect to the comparison object; and
- the value at offset `off` within the value container is the value associated with the key at offset `off` within the key container.

If any member function in 24.6.9.2 exits via an exception the invariants are restored.

NOTE 2 This can result in the `flat_map` being emptied.

Any type `C` that meets the sequence container requirements (24.2.4) can be used to instantiate `flat_map`, as long as `C::iterator` meets the *Cpp17RandomAccessIterator* requirements and invocations of member functions `C::size` and `C::max_size` do not exit via an exception. In particular, `vector` (24.3.11) and `deque` (24.3.8) can be used.

NOTE 3 `vector<bool>` is not a sequence container.

The program is ill-formed if `Key` is not the same type as `KeyContainer::value_type` or `T` is not the same type as `MappedContainer::value_type`.

The effect of calling a constructor that takes both `key_container_type` and `mapped_container_type` arguments with containers of different sizes is undefined.

The effect of calling a constructor or member function that takes a `sorted_unique_t` argument with a container, containers, or range that is not sorted with respect to `key_comp()`, or that contains equal elements, is undefined.

24.6.9.2 Definition

[flat.map.defn]

```
namespace std {
    template<class Key, class T, class Compare = less<Key>,
            class KeyContainer = vector<Key>, class MappedContainer = vector<T>>
    class flat_map {
    public:
        // types
        using key_type           = Key;
        using mapped_type        = T;
        using value_type         = pair<key_type, mapped_type>;
        using key_compare        = Compare;
        using reference          = pair<const key_type&, mapped_type&>;
        using const_reference    = pair<const key_type&, const mapped_type&>;

```

The member type `containers` has the data members and special members specified above. It has no base classes or members other than those specified.

24.6.9.3 Constructors [flat.map.cons]

```

flat_map(key_container_type key_cont, mapped_container_type mapped_cont,
const key_compare& comp = key_compare());

```

Effects: Initializes `c.keys` with `std::move(key_cont)`, `c.values` with `std::move(mapped_cont)`, and `compare` with `comp`; sorts the range `[begin(), end())` with respect to `value_comp()`; and finally erases the duplicate elements as if by:

```

auto zv = ranges::zip_view(c.keys, c.values);
auto it = ranges::unique(zv, key_equiv(compare)).begin();
auto dist = distance(zv.begin(), it);
c.keys.erase(c.keys.begin() + dist, c.keys.end());
c.values.erase(c.values.begin() + dist, c.values.end());

```

Complexity: Linear in N if the container arguments are already sorted with respect to `value_comp()` and otherwise $N \log N$, where N is the value of `key_cont.size()` before this call.

```

template<class Allocator>
flat_map(const key_container_type& key_cont, const mapped_container_type& mapped_cont,
const Allocator& a);

```

```

template<class Allocator>
flat_map(const key_container_type& key_cont, const mapped_container_type& mapped_cont,
         const key_compare& comp, const Allocator& a);

    Constraints: uses_allocator_v<key_container_type, Allocator> is true and uses_allocator_v<mapped_container_type, Allocator> is true.

    Effects: Equivalent to flat_map(key_cont, mapped_cont) and flat_map(key_cont, mapped_cont, comp), respectively, except that c.keys and c.values are constructed with uses-allocator construction (20.2.8.2).

    Complexity: Same as flat_map(key_cont, mapped_cont) and flat_map(key_cont, mapped_cont, comp), respectively.

flat_map(sorted_unique_t, key_container_type key_cont, mapped_container_type mapped_cont,
         const key_compare& comp = key_compare());

    Effects: Initializes c.keys with std::move(key_cont), c.values with std::move(mapped_cont), and compare with comp.

    Complexity: Constant.

template<class Allocator>
flat_map(sorted_unique_t s, const key_container_type& key_cont,
         const mapped_container_type& mapped_cont, const Allocator& a);
template<class Allocator>
flat_map(sorted_unique_t s, const key_container_type& key_cont,
         const mapped_container_type& mapped_cont, const key_compare& comp,
         const Allocator& a);

    Constraints: uses_allocator_v<key_container_type, Allocator> is true and uses_allocator_v<mapped_container_type, Allocator> is true.

    Effects: Equivalent to flat_map(s, key_cont, mapped_cont) and flat_map(s, key_cont, mapped_cont, comp), respectively, except that c.keys and c.values are constructed with uses-allocator construction (20.2.8.2).

    Complexity: Linear.

template<class Allocator>
flat_map(const key_compare& comp, const Allocator& a);
template<class Allocator>
explicit flat_map(const Allocator& a);
template<class InputIterator, class Allocator>
flat_map(InputIterator first, InputIterator last, const key_compare& comp, const Allocator& a);
template<class InputIterator, class Allocator>
flat_map(InputIterator first, InputIterator last, const Allocator& a);

flat_map(from_range_t, R&& rg, const Allocator& a);
template<container_compatible_range<value_type> R, class Allocator>
flat_map(from_range_t, R&& rg, const key_compare& comp, const Allocator& a);
template<class InputIterator, class Allocator>
flat_map(sorted_unique_t, InputIterator first, InputIterator last,
         const key_compare& comp, const Allocator& a);
template<class InputIterator, class Allocator>
flat_map(sorted_unique_t, InputIterator first, InputIterator last, const Allocator& a);
template<class Allocator>
flat_map(initializer_list<value_type> il, const key_compare& comp, const Allocator& a);
template<class Allocator>
flat_map(initializer_list<value_type> il, const Allocator& a);
template<class Allocator>
flat_map(sorted_unique_t, initializer_list<value_type> il,
         const key_compare& comp, const Allocator& a);
template<class Allocator>
flat_map(sorted_unique_t, initializer_list<value_type> il, const Allocator& a);

    Constraints: uses_allocator_v<key_container_type, Allocator> is true and uses_allocator_v<mapped_container_type, Allocator> is true.

```

Effects: Equivalent to the corresponding non-allocator constructors except that `c.keys` and `c.values` are constructed with uses-allocator construction (20.2.8.2).

24.6.9.4 Capacity

[flat.map.capacity]

```
size_type size() const noexcept;
```

Returns: `c.keys.size()`.

```
size_type max_size() const noexcept;
```

Returns: `min<size_type>(c.keys.max_size(), c.values.max_size())`.

24.6.9.5 Access

[flat.map.access]

```
mapped_type& operator[](const key_type& x);
```

Effects: Equivalent to: `return try_emplace(x).first->second;`

```
mapped_type& operator[](key_type&& x);
```

Effects: Equivalent to: `return try_emplace(std::move(x)).first->second;`

```
template<class K> mapped_type& operator[](K&& x);
```

Constraints: The *qualified-id* `Compare::is_transparent` is valid and denotes a type.

Effects: Equivalent to: `return try_emplace(std::forward<K>(x)).first->second;`

```
mapped_type& at(const key_type& x);
```

```
const mapped_type& at(const key_type& x) const;
```

Returns: A reference to the `mapped_type` corresponding to `x` in `*this`.

Throws: An exception object of type `out_of_range` if no such element is present.

Complexity: Logarithmic.

```
template<class K> mapped_type& at(const K& x);
```

```
template<class K> const mapped_type& at(const K& x) const;
```

Constraints: The *qualified-id* `Compare::is_transparent` is valid and denotes a type.

Preconditions: The expression `find(x)` is well-formed and has well-defined behavior.

Returns: A reference to the `mapped_type` corresponding to `x` in `*this`.

Throws: An exception object of type `out_of_range` if no such element is present.

Complexity: Logarithmic.

24.6.9.6 Modifiers

[flat.map.modifiers]

```
template<class... Args> pair<iterator, bool> emplace(Args&&... args);
```

Constraints: `is_constructible_v<pair<key_type, mapped_type>, Args...>` is true.

Effects: Initializes an object `t` of type `pair<key_type, mapped_type>` with `std::forward<Args>(args)...`; if the map already contains an element whose key is equivalent to `t.first`, `*this` is unchanged. Otherwise, equivalent to:

```
auto key_it = ranges::upper_bound(c.keys, t.first, compare);
auto value_it = c.values.begin() + distance(c.keys.begin(), key_it);
c.keys.insert(key_it, std::move(t.first));
c.values.insert(value_it, std::move(t.second));
```

Returns: The `bool` component of the returned pair is `true` if and only if the insertion took place, and the iterator component of the pair points to the element with key equivalent to `t.first`.

```
template<class P> pair<iterator, bool> insert(P&& x);
```

```
template<class P> iterator insert(const_iterator position, P&& x);
```

Constraints: `is_constructible_v<pair<key_type, mapped_type>, P>` is true.

Effects: The first form is equivalent to `return emplace(std::forward<P>(x));`. The second form is equivalent to `return emplace_hint(position, std::forward<P>(x));`.

```
template<class InputIterator>
void insert(InputIterator first, InputIterator last);
```

Effects: Adds elements to *c* as if by:

```
for (; first != last; ++first) {
    value_type value = *first;
    c.keys.insert(c.keys.end(), std::move(value.first));
    c.values.insert(c.values.end(), std::move(value.second));
}
```

Then, sorts the range of newly inserted elements with respect to `value_comp()`; merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases the duplicate elements as if by:

```
auto zv = ranges::zip_view(c.keys, c.values);
auto it = ranges::unique(zv, key_equiv(compare)).begin();
auto dist = distance(zv.begin(), it);
c.keys.erase(c.keys.begin() + dist, c.keys.end());
c.values.erase(c.values.begin() + dist, c.values.end());
```

Complexity: $N + M \log M$, where N is `size()` before the operation and M is `distance(first, last)`.

Remarks: Since this operation performs an in-place merge, it may allocate memory.

```
template<class InputIterator>
void insert(sorted_unique_t, InputIterator first, InputIterator last);
```

Effects: Adds elements to *c* as if by:

```
for (; first != last; ++first) {
    value_type value = *first;
    c.keys.insert(c.keys.end(), std::move(value.first));
    c.values.insert(c.values.end(), std::move(value.second));
}
```

Then, merges the sorted range of newly added elements and the sorted range of pre-existing elements into a single sorted range; and finally erases the duplicate elements as if by:

```
auto zv = ranges::zip_view(c.keys, c.values);
auto it = ranges::unique(zv, key_equiv(compare)).begin();
auto dist = distance(zv.begin(), it);
c.keys.erase(c.keys.begin() + dist, c.keys.end());
c.values.erase(c.values.begin() + dist, c.values.end());
```

Complexity: Linear in N , where N is `size()` after the operation.

Remarks: Since this operation performs an in-place merge, it may allocate memory.

```
template<container-compatible-range<value_type> R>
void insert_range(R&& rg);
```

Effects: Adds elements to *c* as if by:

```
for (const auto& e : rg) {
    c.keys.insert(c.keys.end(), e.first);
    c.values.insert(c.values.end(), e.second);
}
```

Then, sorts the range of newly inserted elements with respect to `value_comp()`; merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases the duplicate elements as if by:

```
auto zv = ranges::zip_view(c.keys, c.values);
auto it = ranges::unique(zv, key_equiv(compare)).begin();
auto dist = distance(zv.begin(), it);
c.keys.erase(c.keys.begin() + dist, c.keys.end());
c.values.erase(c.values.begin() + dist, c.values.end());
```

Complexity: $N + M \log M$, where N is `size()` before the operation and M is `ranges::distance(rg)`.

Remarks: Since this operation performs an in-place merge, it may allocate memory.

```

template<class... Args>
    pair<iterator, bool> try_emplace(const key_type& k, Args&&... args);
template<class... Args>
    pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);
template<class... Args>
    iterator try_emplace(const_iterator hint, const key_type& k, Args&&... args);
template<class... Args>
    iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);

```

Constraints: `is_constructible_v<mapped_type, Args...>` is true.

Effects: If the map already contains an element whose key is equivalent to `k`, `*this` and `args...` are unchanged. Otherwise equivalent to:

```

    auto key_it = ranges::upper_bound(c.keys, k, compare);
    auto value_it = c.values.begin() + distance(c.keys.begin(), key_it);
    c.keys.insert(key_it, std::forward<decltype(k)>(k));
    c.values.emplace(value_it, std::forward<Args>(args)...);

```

Returns: In the first two overloads, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

Complexity: The same as `emplace` for the first two overloads, and the same as `emplace_hint` for the last two overloads.

```

template<class K, class... Args>
    pair<iterator, bool> try_emplace(K&& k, Args&&... args);
template<class K, class... Args>
    iterator try_emplace(const_iterator hint, K&& k, Args&&... args);

```

Constraints:

- The *qualified-id* `Compare::is_transparent` is valid and denotes a type.
- `is_constructible_v<key_type, K>` is true.
- `is_constructible_v<mapped_type, Args...>` is true.
- For the first overload, `is_convertible_v<K&&, const_iterator>` and `is_convertible_v<K&&, iterator>` are both false.

Preconditions: The conversion from `k` into `key_type` constructs an object `u`, for which `find(k) == find(u)` is true.

Effects: If the map already contains an element whose key is equivalent to `k`, `*this` and `args...` are unchanged. Otherwise equivalent to:

```

    auto key_it = ranges::upper_bound(c.keys, k, compare);
    auto value_it = c.values.begin() + distance(c.keys.begin(), key_it);
    c.keys.emplace(key_it, std::forward<K>(k));
    c.values.emplace(value_it, std::forward<Args>(args)...);

```

Returns: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

Complexity: The same as `emplace` and `emplace_hint`, respectively.

```

template<class M>
    pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);
template<class M>
    pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);
template<class M>
    iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);
template<class M>
    iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);

```

Constraints: `is_assignable_v<mapped_type&, M>` is true and `is_constructible_v<mapped_type, M>` is true.

Effects: If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::forward<M>(obj)` to `e.second`. Otherwise, equivalent to

```

    try_emplace(std::forward<decltype(k)>(k), std::forward<M>(obj))

```

for the first two overloads or

```
try_emplace(hint, std::forward<decltype(k)>(k), std::forward<M>(obj))
```

for the last two overloads.

Returns: In the first two overloads, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

Complexity: The same as `emplace` for the first two overloads and the same as `emplace_hint` for the last two overloads.

```
template<class K, class M>
pair<iterator, bool> insert_or_assign(K&& k, M&& obj);
template<class K, class M>
iterator insert_or_assign(const_iterator hint, K&& k, M&& obj);
```

Constraints:

- The *qualified-id* `Compare::is_transparent` is valid and denotes a type.
- `is_constructible_v<key_type, K>` is true.
- `is_assignable_v<mapped_type&, M>` is true.
- `is_constructible_v<mapped_type, M>` is true.

Preconditions: The conversion from `k` into `key_type` constructs an object `u`, for which `find(k) == find(u)` is true.

Effects: If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::forward<M>(obj)` to `e.second`. Otherwise, equivalent to

```
try_emplace(std::forward<K>(k), std::forward<M>(obj))
```

for the first overload or

```
try_emplace(hint, std::forward<K>(k), std::forward<M>(obj))
```

for the second overload.

Returns: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

Complexity: The same as `emplace` and `emplace_hint`, respectively.

```
void swap(flat_map& y) noexcept;
```

Effects: Equivalent to:

```
ranges::swap(compare, y.compare);
ranges::swap(c.keys, y.c.keys);
ranges::swap(c.values, y.c.values);
```

```
containers extract() &&;
```

Postconditions: `*this` is emptied, even if the function exits via an exception.

Returns: `std::move(c)`.

```
void replace(key_container_type&& key_cont, mapped_container_type&& mapped_cont);
```

Preconditions: `key_cont.size() == mapped_cont.size()` is true, the elements of `key_cont` are sorted with respect to `compare`, and `key_cont` contains no equal elements.

Effects: Equivalent to:

```
c.keys = std::move(key_cont);
c.values = std::move(mapped_cont);
```

24.6.9.7 Erasure

[flat.map.erase]

```
template<class Key, class T, class Compare, class KeyContainer, class MappedContainer,
class Predicate>
typename flat_map<Key, T, Compare, KeyContainer, MappedContainer>::size_type
erase_if(flat_map<Key, T, Compare, KeyContainer, MappedContainer>& c, Predicate pred);
```

Preconditions: `Key` and `T` meet the *Cpp17MoveAssignable* requirements.

Effects: Let E be `bool(pred(pair<const Key&, const T&>(e)))`. Erases all elements e in c for which E holds.

Returns: The number of elements erased.

Complexity: Exactly `c.size()` applications of the predicate.

Remarks: Stable (16.4.6.8). If an invocation of `erase_if` exits via an exception, c is in a valid but unspecified state (3.64).

NOTE c still meets its invariants, but can be empty.

24.6.10 Class template `flat_multimap`

[`flat_multimap`]

24.6.10.1 Overview

[`flat_multimap.overview`]

A `flat_multimap` is a container adaptor that provides an associative container interface that supports equivalent keys (i.e., possibly containing multiple copies of the same key value) and provides for fast retrieval of values of another type T based on the keys. `flat_multimap` supports iterators that meet the *Cpp17InputIterator* requirements and model the `random_access_iterator` concept (25.3.4.43).

A `flat_multimap` meets all of the requirements for a container (24.2.2.2) and for a reversible container (24.2.2.3), plus the optional container requirements (24.2.2.4). `flat_multimap` meets the requirements of an associative container (24.2.7), except that:

- it does not meet the requirements related to node handles (24.2.5),
- it does not meet the requirements related to iterator invalidation, and
- the time complexity of the operations that insert or erase a single element from the map is linear, including the ones that take an insertion position iterator.

NOTE 1 A `flat_multimap` does not meet the additional requirements of an allocator-aware container (24.2.2.5).

A `flat_multimap` also provides most operations described in 24.2.7 for equal keys. This means that a `flat_multimap` supports the `a_eq` operations in 24.2.7 but not the `a_uniq` operations. For a `flat_multimap<Key, T>` the `key_type` is `Key` and the `value_type` is `pair<Key, T>`.

Except as otherwise noted, operations on `flat_multimap` are equivalent to those of `flat_map`, except that `flat_multimap` operations do not remove or replace elements with equal keys.

EXAMPLE `flat_multimap` constructors and `emplace` do not erase non-unique elements after sorting them.

A `flat_multimap` maintains the following invariants:

- it contains the same number of keys and values;
- the keys are sorted with respect to the comparison object; and
- the value at offset `off` within the value container is the value associated with the key at offset `off` within the key container.

If any member function in 24.6.10.2 exits via an exception, the invariants are restored.

NOTE 2 This can result in the `flat_multimap` being emptied.

Any type C that meets the sequence container requirements (24.2.4) can be used to instantiate `flat_multimap`, as long as `C::iterator` meets the *Cpp17RandomAccessIterator* requirements and invocations of member functions `C::size` and `C::max_size` do not exit via an exception. In particular, `vector` (24.3.11) and `deque` (24.3.8) can be used.

NOTE 3 `vector<bool>` is not a sequence container.

The program is ill-formed if `Key` is not the same type as `KeyContainer::value_type` or T is not the same type as `MappedContainer::value_type`.

The effect of calling a constructor that takes both `key_container_type` and `mapped_container_type` arguments with containers of different sizes is undefined.

The effect of calling a constructor or member function that takes a `sorted_equivalent_t` argument with a container, containers, or range that are not sorted with respect to `key_comp()` is undefined.

24.6.10.2 Definition

[flat.multimap.defn]

```

namespace std {
    template<class Key, class T, class Compare = less<Key>,
            class KeyContainer = vector<Key>, class MappedContainer = vector<T>>
    class flat_multimap {
    public:
        // types
        using key_type           = Key;
        using mapped_type        = T;
        using value_type         = pair<key_type, mapped_type>;
        using key_compare        = Compare;

24.6.10.3 Constructors

[flat.multimap.cons]

```

flat_multimap(key_container_type key_cont, mapped_container_type mapped_cont,
const key_compare& comp = key_compare());

```

Effects: Initializes `c.keys` with `std::move(key_cont)`, `c.values` with `std::move(mapped_cont)`, and `compare` with `comp`; sorts the range `[begin(), end())` with respect to `value_comp()`.

Complexity: Linear in N if the container arguments are already sorted with respect to `value_comp()` and otherwise $N \log N$, where N is the value of `key_cont.size()` before this call.

```

template<class Allocator>
    flat_multimap(const key_container_type& key_cont, const mapped_container_type& mapped_cont,
                  const Allocator& a);
template<class Allocator>
    flat_multimap(const key_container_type& key_cont, const mapped_container_type& mapped_cont,
                  const key_compare& comp, const Allocator& a);

    Constraints: uses_allocator_v<key_container_type, Allocator> is true and uses_allocator_v<mapped_container_type, Allocator> is true.

    Effects: Equivalent to flat_multimap(key_cont, mapped_cont) and flat_multimap(key_cont, mapped_cont, comp), respectively, except that c.keys and c.values are constructed with uses_allocator construction (20.2.8.2).

    Complexity: Same as flat_multimap(key_cont, mapped_cont) and flat_multimap(key_cont, mapped_cont, comp), respectively.

flat_multimap(sorted_equivalent_t, key_container_type key_cont, mapped_container_type mapped_cont,
              const key_compare& comp = key_compare());

    Effects: Initializes c.keys with std::move(key_cont), c.values with std::move(mapped_cont), and compare with comp.

    Complexity: Constant.

template<class Allocator>
    flat_multimap(sorted_equivalent_t s, const key_container_type& key_cont,
                  const mapped_container_type& mapped_cont, const Allocator& a);
template<class Allocator>
    flat_multimap(sorted_equivalent_t s, const key_container_type& key_cont,
                  const mapped_container_type& mapped_cont, const key_compare& comp,
                  const Allocator& a);

    Constraints: uses_allocator_v<key_container_type, Allocator> is true and uses_allocator_v<mapped_container_type, Allocator> is true.

    Effects: Equivalent to flat_multimap(s, key_cont, mapped_cont) and flat_multimap(s, key_cont, mapped_cont, comp), respectively, except that c.keys and c.values are constructed with uses_allocator construction (20.2.8.2).

    Complexity: Linear.

template<class Allocator>
    flat_multimap(const key_compare& comp, const Allocator& a);
template<class Allocator>
    explicit flat_multimap(const Allocator& a);
template<class InputIterator, class Allocator>
    flat_multimap(InputIterator first, InputIterator last, const key_compare& comp,
                  const Allocator& a);
template<class InputIterator, class Allocator>
    flat_multimap(InputIterator first, InputIterator last, const Allocator& a);
template<container-compatible-range<value_type> R, class Allocator>
    flat_multimap(from_range_t, R&& rg, const Allocator& a);
template<container-compatible-range<value_type> R, class Allocator>
    flat_multimap(from_range_t, R&& rg, const key_compare& comp, const Allocator& a);
template<class InputIterator, class Allocator>
    flat_multimap(sorted_equivalent_t, InputIterator first, InputIterator last,
                  const key_compare& comp, const Allocator& a);
template<class InputIterator, class Allocator>
    flat_multimap(sorted_equivalent_t, InputIterator first, InputIterator last,
                  const Allocator& a);
template<class Allocator>
    flat_multimap(initializer_list<value_type> il, const key_compare& comp, const Allocator& a);
template<class Allocator>
    flat_multimap(initializer_list<value_type> il, const Allocator& a);
template<class Allocator>
    flat_multimap(sorted_equivalent_t, initializer_list<value_type> il,
                  const key_compare& comp, const Allocator& a);

```

```
template<class Allocator>
```

```
    flat_multimap(sorted_equivalent_t, initializer_list<value_type> il, const Allocator& a);
```

Constraints: `uses_allocator_v<key_container_type, Allocator>` is true and `uses_allocator_v<mapped_container_type, Allocator>` is true.

Effects: Equivalent to the corresponding non-allocator constructors except that `c.keys` and `c.values` are constructed with uses-allocator construction (20.2.8.2).

24.6.10.4 Erasure

[flat.multimap.erase]

```
template<class Key, class T, class Compare, class KeyContainer, class MappedContainer,
        class Predicate>
```

```
    typename flat_multimap<Key, T, Compare, KeyContainer, MappedContainer>::size_type
```

```
    erase_if(flat_multimap<Key, T, Compare, KeyContainer, MappedContainer>& c, Predicate pred);
```

Preconditions: `Key` and `T` meet the *Cpp17MoveAssignable* requirements.

Effects: Let E be `bool(pred(pair<const Key&, const T&>(e)))`. Erases all elements e in c for which E holds.

Returns: The number of elements erased.

Complexity: Exactly `c.size()` applications of the predicate.

Remarks: Stable (16.4.6.8). If an invocation of `erase_if` exits via an exception, c is in a valid but unspecified state (3.64).

NOTE c still meets its invariants, but can be empty.

24.6.11 Class template flat_set

[flat.set]

24.6.11.1 Overview

[flat.set.overview]

A `flat_set` is a container adaptor that provides an associative container interface that supports unique keys (i.e., contains at most one of each key value) and provides for fast retrieval of the keys themselves. `flat_set` supports iterators that model the *random_access_iterator* concept (25.3.4.13).

A `flat_set` meets all of the requirements for a container (24.2.2.2) and for a reversible container (24.2.2.3), plus the optional container requirements (24.2.2.4). `flat_set` meets the requirements of an associative container (24.2.7), except that:

- it does not meet the requirements related to node handles (24.2.5.1),
- it does not meet the requirements related to iterator invalidation, and
- the time complexity of the operations that insert or erase a single element from the set is linear, including the ones that take an insertion position iterator.

NOTE 1 A `flat_set` does not meet the additional requirements of an allocator-aware container, as described in 24.2.2.5.

A `flat_set` also provides most operations described in 24.2.7 for unique keys. This means that a `flat_set` supports the *a_uniq* operations in 24.2.7 but not the *a_eq* operations. For a `flat_set<Key>`, both the `key_type` and `value_type` are `Key`.

Descriptions are provided here only for operations on `flat_set` that are not described in one of those sets of requirements or for operations where there is additional semantic information.

A `flat_set` maintains the invariant that the keys are sorted with respect to the comparison object.

If any member function in 24.6.11.2 exits via an exception, the invariant is restored.

NOTE 2 This can result in the `flat_set`'s being emptied.

Any sequence container (24.2.4) supporting *Cpp17RandomAccessIterator* can be used to instantiate `flat_set`. In particular, `vector` (24.3.11) and `deque` (24.3.8) can be used.

NOTE 3 `vector<bool>` is not a sequence container.

The program is ill-formed if `Key` is not the same type as `KeyContainer::value_type`.

The effect of calling a constructor or member function that takes a `sorted_unique_t` argument with a range that is not sorted with respect to `key_comp()`, or that contains equal elements, is undefined.

24.6.11.2 Definition

[flat.set.defn]

```

    -> flat_set<Key, Compare>;

```

```

template<class Key, class Compare, class KeyContainer, class Allocator>
    struct uses_allocator<flat_set<Key, Compare, KeyContainer>, Allocator>
        : bool_constant<uses_allocator_v<KeyContainer, Allocator>> { };
}

```

24.6.11.3 Constructors

[flat.set.cons]

```
explicit flat_set(container_type cont, const key_compare& comp = key_compare());
```

Effects: Initializes *c* with `std::move(cont)` and *compare* with *comp*, sorts the range `[begin(), end())` with respect to *compare*, and finally erases all but the first element from each group of consecutive equivalent elements.

Complexity: Linear in *N* if *cont* is sorted with respect to *compare* and otherwise $N \log N$, where *N* is the value of *cont.size()* before this call.

```

template<class Allocator>
    flat_set(const container_type& cont, const Allocator& a);
template<class Allocator>
    flat_set(const container_type& cont, const key_compare& comp, const Allocator& a);

```

Constraints: `uses_allocator_v<container_type, Allocator>` is true.

Effects: Equivalent to `flat_set(cont)` and `flat_set(cont, comp)`, respectively, except that *c* is constructed with uses-allocator construction (20.2.8.2).

Complexity: Same as `flat_set(cont)` and `flat_set(cont, comp)`, respectively.

```

template<class Allocator>
    flat_set(sorted_unique_t s, const container_type& cont, const Allocator& a);
template<class Allocator>
    flat_set(sorted_unique_t s, const container_type& cont,
        const key_compare& comp, const Allocator& a);

```

Constraints: `uses_allocator_v<container_type, Allocator>` is true.

Effects: Equivalent to `flat_set(s, cont)` and `flat_set(s, cont, comp)`, respectively, except that *c* is constructed with uses-allocator construction (20.2.8.2).

Complexity: Linear.

```

template<class Allocator>
    flat_set(const key_compare& comp, const Allocator& a);
template<class Allocator>
    explicit flat_set(const Allocator& a);
template<class InputIterator, class Allocator>
    flat_set(InputIterator first, InputIterator last, const key_compare& comp, const Allocator& a);
template<class InputIterator, class Allocator>
    flat_set(InputIterator first, InputIterator last, const Allocator& a);
template<container_compatible_range<value_type> R, class Allocator>
    flat_set(from_range_t, R&& rg, const Allocator& a);
template<container_compatible_range<value_type> R, class Allocator>
    flat_set(from_range_t, R&& rg, const key_compare& comp, const Allocator& a);
template<class InputIterator, class Allocator>
    flat_set(sorted_unique_t, InputIterator first, InputIterator last,
        const key_compare& comp, const Allocator& a);
template<class InputIterator, class Allocator>
    flat_set(sorted_unique_t, InputIterator first, InputIterator last, const Allocator& a);
template<class Allocator>
    flat_set(initializer_list<value_type> il, const key_compare& comp, const Allocator& a);
template<class Allocator>
    flat_set(initializer_list<value_type> il, const Allocator& a);
template<class Allocator>
    flat_set(sorted_unique_t, initializer_list<value_type> il,
        const key_compare& comp, const Allocator& a);
template<class Allocator>
    flat_set(sorted_unique_t, initializer_list<value_type> il, const Allocator& a);

```

Constraints: `uses_allocator_v<container_type, Allocator>` is true.

Effects: Equivalent to the corresponding non-allocator constructors except that `c` is constructed with uses-allocator construction (20.2.8.2).

24.6.11.4 Modifiers

[flat.set.modifiers]

```
template<class K> pair<iterator, bool> insert(K&& x);
template<class K> iterator insert(const_iterator hint, K&& x);
```

Constraints: The *qualified-id* `Compare::is_transparent` is valid and denotes a type. `is_constructible_v<value_type, K>` is true.

Preconditions: The conversion from `x` into `value_type` constructs an object `u`, for which `find(x) == find(u)` is true.

Effects: If the set already contains an element equivalent to `x`, `*this` and `x` are unchanged. Otherwise, inserts a new element as if by `emplace(std::forward<K>(x))`.

Returns: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the element whose key is equivalent to `x`.

```
template<class InputIterator>
void insert(InputIterator first, InputIterator last);
```

Effects: Adds elements to `c` as if by:

```
c.insert(c.end(), first, last);
```

Then, sorts the range of newly inserted elements with respect to `compare`; merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases all but the first element from each group of consecutive equivalent elements.

Complexity: $N + M \log M$, where N is `size()` before the operation and M is `distance(first, last)`.

Remarks: Since this operation performs an in-place merge, it may allocate memory.

```
template<class InputIterator>
void insert(sorted_unique_t, InputIterator first, InputIterator last);
```

Effects: Equivalent to `insert(first, last)`.

Complexity: Linear.

```
template<container-compatible-range<value_type> R>
void insert_range(R&& rg);
```

Effects: Adds elements to `c` as if by:

```
for (const auto& e : rg) {
    c.insert(c.end(), e);
}
```

Then, sorts the range of newly inserted elements with respect to `compare`; merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases all but the first element from each group of consecutive equivalent elements.

Complexity: $N + M \log M$, where N is `size()` before the operation and M is `ranges::distance(rg)`.

Remarks: Since this operation performs an in-place merge, it may allocate memory.

```
void swap(flat_set& y) noexcept;
```

Effects: Equivalent to:

```
ranges::swap(compare, y.compare);
ranges::swap(c, y.c);
```

```
container_type extract() &&;
```

Postconditions: `*this` is emptied, even if the function exits via an exception.

Returns: `std::move(c)`.

```
void replace(container_type&& cont);
```

Preconditions: The elements of `cont` are sorted with respect to `compare`, and `cont` contains no equal elements.

Effects: Equivalent to: `c = std::move(cont);`

24.6.11.5 Erasure

[flat.set.erase]

```
template<class Key, class Compare, class KeyContainer, class Predicate>
typename flat_set<Key, Compare, KeyContainer>::size_type
erase_if(flat_set<Key, Compare, KeyContainer>& c, Predicate pred);
```

Preconditions: Key meets the *Cpp17MoveAssignable* requirements.

Effects: Let E be `bool(pred(as_const(e)))`. Erases all elements e in c for which E holds.

Returns: The number of elements erased.

Complexity: Exactly `c.size()` applications of the predicate.

Remarks: Stable (16.4.6.8). If an invocation of `erase_if` exits via an exception, c is in a valid but unspecified state (3.64).

NOTE c still meets its invariants, but can be empty.

24.6.12 Class template flat_multiset

[flat.multiset]

24.6.12.1 Overview

[flat.multiset.overview]

A `flat_multiset` is a container adaptor that provides an associative container interface that supports equivalent keys (i.e., possibly containing multiple copies of the same key value) and provides for fast retrieval of the keys themselves. `flat_multiset` supports iterators that model the `random_access_iterator` concept (25.3.4.13).

A `flat_multiset` meets all of the requirements for a container (24.2.2.2) and for a reversible container (24.2.2.3), plus the optional container requirements (24.2.2.4). `flat_multiset` meets the requirements of an associative container (24.2.7), except that:

- it does not meet the requirements related to node handles (24.2.5.1),
- it does not meet the requirements related to iterator invalidation, and
- the time complexity of the operations that insert or erase a single element from the set is linear, including the ones that take an insertion position iterator.

NOTE 1 A `flat_multiset` does not meet the additional requirements of an allocator-aware container, as described in 24.2.2.5.

A `flat_multiset` also provides most operations described in 24.2.7 for equal keys. This means that a `flat_multiset` supports the `a_eq` operations in 24.2.7 but not the `a_uniq` operations. For a `flat_multiset<Key>`, both the `key_type` and `value_type` are `Key`.

Descriptions are provided here only for operations on `flat_multiset` that are not described in one of the general sections or for operations where there is additional semantic information.

A `flat_multiset` maintains the invariant that the keys are sorted with respect to the comparison object.

If any member function in 24.6.12.2 exits via an exception, the invariant is restored.

NOTE 2 This can result in the `flat_multiset`'s being emptied.

Any sequence container (24.2.4) supporting *Cpp17RandomAccessIterator* can be used to instantiate `flat_multiset`. In particular, `vector` (24.3.11) and `deque` (24.3.8) can be used.

NOTE 3 `vector<bool>` is not a sequence container.

The program is ill-formed if `Key` is not the same type as `KeyContainer::value_type`.

The effect of calling a constructor or member function that takes a `sorted_equivalent_t` argument with a range that is not sorted with respect to `key_comp()` is undefined.

24.6.12.2 Definition

[flat.multiset.defn]

```
namespace std {
    template<class Key, class Compare = less<Key>, class KeyContainer = vector<Key>>
    class flat_multiset {

24.6.12.3 Constructors

[flat.multiset.cons]

```
explicit flat_multiset(container_type cont, const key_compare& comp = key_compare());
```

Effects: Initializes *c* with `std::move(cont)` and *compare* with *comp*, and sorts the range `[begin(), end())` with respect to *compare*.

Complexity: Linear in *N* if *cont* is sorted with respect to *compare* and otherwise $N \log N$, where *N* is the value of `cont.size()` before this call.

```
template<class Allocator>
    flat_multiset(const container_type& cont, const Allocator& a);
template<class Allocator>
    flat_multiset(const container_type& cont, const key_compare& comp, const Allocator& a);
```

Constraints: `uses_allocator_v<container_type, Allocator>` is true.

Effects: Equivalent to `flat_multiset(cont)` and `flat_multiset(cont, comp)`, respectively, except that *c* is constructed with uses-allocator construction (20.2.8.2).

Complexity: Same as `flat_multiset(cont)` and `flat_multiset(cont, comp)`, respectively.

```
template<class Allocator>
    flat_multiset(sorted_equivalent_t s, const container_type& cont, const Allocator& a);
template<class Allocator>
    flat_multiset(sorted_equivalent_t s, const container_type& cont,
                  const key_compare& comp, const Allocator& a);
```

Constraints: `uses_allocator_v<container_type, Allocator>` is true.

Effects: Equivalent to `flat_multiset(s, cont)` and `flat_multiset(s, cont, comp)`, respectively, except that *c* is constructed with uses-allocator construction (20.2.8.2).

Complexity: Linear.

```
template<class Allocator>
    flat_multiset(const key_compare& comp, const Allocator& a);
template<class Allocator>
    explicit flat_multiset(const Allocator& a);
template<class InputIterator, class Allocator>
    flat_multiset(InputIterator first, InputIterator last,
                  const key_compare& comp, const Allocator& a);
template<class InputIterator, class Allocator>
    flat_multiset(InputIterator first, InputIterator last, const Allocator& a);
template<container-compatible-range<value_type> R, class Allocator>
    flat_multiset(from_range_t, R&& rg, const Allocator& a);

    flat_multiset(from_range_t, R&& rg, const key_compare& comp, const Allocator& a);
template<class InputIterator, class Allocator>
    flat_multiset(sorted_equivalent_t, InputIterator first, InputIterator last,
                  const key_compare& comp, const Allocator& a);
template<class InputIterator, class Allocator>
    flat_multiset(sorted_equivalent_t, InputIterator first, InputIterator last, const Allocator& a);
template<class Allocator>
    flat_multiset(initializer_list<value_type> il, const key_compare& comp, const Allocator& a);
template<class Allocator>
    flat_multiset(initializer_list<value_type> il, const Allocator& a);
template<class Allocator>
    flat_multiset(sorted_equivalent_t, initializer_list<value_type> il,
                  const key_compare& comp, const Allocator& a);
template<class Allocator>
    flat_multiset(sorted_equivalent_t, initializer_list<value_type> il, const Allocator& a);
```

Constraints: `uses_allocator_v<container_type, Allocator>` is true.

Effects: Equivalent to the corresponding non-allocator constructors except that *c* is constructed with uses-allocator construction (20.2.8.2).

24.6.12.4 Modifiers

[flat.multiset.modifiers]

```
template<class... Args> iterator emplace(Args&&... args);
```

Constraints: `is_constructible_v<value_type, Args...>` is true.

Effects: First, initializes an object `t` of type `value_type` with `std::forward<Args>(args)...`, then inserts `t` as if by:

```
auto it = ranges::upper_bound(c, t, compare);
c.insert(it, std::move(t));
```

Returns: An iterator that points to the inserted element.

```
template<class InputIterator>
void insert(InputIterator first, InputIterator last);
```

Effects: Adds elements to `c` as if by:

```
c.insert(c.end(), first, last);
```

Then, sorts the range of newly inserted elements with respect to `compare`, and merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range.

Complexity: $N + M \log M$, where N is `size()` before the operation and M is `distance(first, last)`.

Remarks: Since this operation performs an in-place merge, it may allocate memory.

```
template<class InputIterator>
void insert(sorted_equivalent_t, InputIterator first, InputIterator last);
```

Effects: Equivalent to `insert(first, last)`.

Complexity: Linear.

```
void swap(flat_multiset& y) noexcept;
```

Effects: Equivalent to:

```
ranges::swap(compare, y.compare);
ranges::swap(c, y.c);
```

```
container_type extract() &&;
```

Postconditions: `*this` is emptied, even if the function exits via an exception.

Returns: `std::move(c)`.

```
void replace(container_type&& cont);
```

Preconditions: The elements of `cont` are sorted with respect to `compare`.

Effects: Equivalent to: `c = std::move(cont)`;

24.6.12.5 Erasure

[flat.multiset.erase]

```
template<class Key, class Compare, class KeyContainer, class Predicate>
typename flat_multiset<Key, Compare, KeyContainer>::size_type
erase_if(flat_multiset<Key, Compare, KeyContainer>& c, Predicate pred);
```

Preconditions: `Key` meets the *Cpp17MoveAssignable* requirements.

Effects: Let E be `bool(pred(as_const(e)))`. Erases all elements e in `c` for which E holds.

Returns: The number of elements erased.

Complexity: Exactly `c.size()` applications of the predicate.

Remarks: Stable (16.4.6.8). If an invocation of `erase_if` exits via an exception, `c` is in a valid but unspecified state (3.64).

NOTE `c` still meets its invariants, but can be empty.

24.6.13 Container adaptors formatting

[container.adaptors.format]

For each of `queue`, `priority_queue`, and `stack`, the library provides the following formatter specialization where *adaptor-type* is the name of the template:

```

namespace std {
    template<class charT, class T, formattable<charT> Container, class... U>
    struct formatter<adaptor-type<T, Container, U...>, charT> {
    private:
        using maybe-const-container = // exposition only
            fmt-maybe-const<Container, charT>;
        using maybe-const-adaptor = // exposition only
            maybe-const<is_const_v<maybe-const-container>,
                adaptor-type<T, Container, U...>>;
        formatter<ranges::ref_view<maybe-const-container>, charT> underlying_; // exposition only

    public:
        template<class ParseContext>
        constexpr typename ParseContext::iterator
            parse(ParseContext& ctx);

        template<class FormatContext>
        typename FormatContext::iterator
            format(maybe-const-adaptor& r, FormatContext& ctx) const;
    };
}

template<class ParseContext>
constexpr typename ParseContext::iterator
    parse(ParseContext& ctx);

Effects: Equivalent to: return underlying_.parse(ctx);

template<class FormatContext>
typename FormatContext::iterator
    format(maybe-const-adaptor& r, FormatContext& ctx) const;

Effects: Equivalent to: return underlying_.format(r.c, ctx);

```

24.7 Views [views]

24.7.1 General [views.general]

The header `<span>` defines the view `span`. The header `<mdspan>` defines the class template `mdspan` and other facilities for interacting with these multidimensional views.

24.7.2 Contiguous access [views.contiguous]

24.7.2.1 Header `<span>` synopsis [span.syn]

```

namespace std {
    // constants
    inline constexpr size_t dynamic_extent = numeric_limits<size_t>::max();

    // 24.7.2.2, class template span
    template<class ElementType, size_t Extent = dynamic_extent>
        class span;

    template<class ElementType, size_t Extent>
        constexpr bool ranges::enable_view<span<ElementType, Extent>> = true;
    template<class ElementType, size_t Extent>
        constexpr bool ranges::enable_borrowed_range<span<ElementType, Extent>> = true;

    // 24.7.2.3, views of object representation
    template<class ElementType, size_t Extent>
        span<const byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
            as_bytes(span<ElementType, Extent> s) noexcept;

    template<class ElementType, size_t Extent>
        span<byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
            as_writable_bytes(span<ElementType, Extent> s) noexcept;
}

```

24.7.2.2 Class template span

[views.span]

24.7.2.2.1 Overview

[span.overview]

A `span` is a view over a contiguous sequence of objects, the storage of which is owned by some other object. All member functions of `span` have constant time complexity.

```

namespace std {
    template<class ElementType, size_t Extent = dynamic_extent>
    class span {
    public:
        // constants and types
        using element_type = ElementType;
        using value_type = remove_cv_t<ElementType>;
        using size_type = size_t;
        using difference_type = ptrdiff_t;
        using pointer = element_type*;
        using const_pointer = const element_type*;
        using reference = element_type&;
        using const_reference = const element_type&;
        using iterator = implementation-defined; // see 24.7.2.2.7
        using const_iterator = std::const_iterator<iterator>;
        using reverse_iterator = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::const_iterator<reverse_iterator>;
        static constexpr size_type extent = Extent;

        // 24.7.2.2.2, constructors, copy, and assignment
        constexpr span() noexcept;
        template<class It>
            constexpr explicit(extent != dynamic_extent) span(It first, size_type count);
        template<class It, class End>
            constexpr explicit(extent != dynamic_extent) span(It first, End last);
        template<size_t N>
            constexpr span(type_identity_t<element_type> (&arr)[N]) noexcept;
        template<class T, size_t N>
            constexpr span(array<T, N>& arr) noexcept;
        template<class T, size_t N>
            constexpr span(const array<T, N>& arr) noexcept;
        template<class R>
            constexpr explicit(extent != dynamic_extent) span(R&& r);
        constexpr span(const span& other) noexcept = default;
        template<class OtherElementType, size_t OtherExtent>
            constexpr explicit(see below) span(const span<OtherElementType, OtherExtent>& s) noexcept;

        ~span() noexcept = default;

        constexpr span& operator=(const span& other) noexcept = default;

        // 24.7.2.2.4, subviews
        template<size_t Count>
            constexpr span<element_type, Count> first() const;
        template<size_t Count>
            constexpr span<element_type, Count> last() const;
        template<size_t Offset, size_t Count = dynamic_extent>
            constexpr span<element_type, see below> subspan() const;

        constexpr span<element_type, dynamic_extent> first(size_type count) const;
        constexpr span<element_type, dynamic_extent> last(size_type count) const;
        constexpr span<element_type, dynamic_extent> subspan(
            size_type offset, size_type count = dynamic_extent) const;

        // 24.7.2.2.5, observers
        constexpr size_type size() const noexcept;
        constexpr size_type size_bytes() const noexcept;
        [[nodiscard]] constexpr bool empty() const noexcept;
    
```

```

// 24.7.2.2.6, element access
constexpr reference operator[](size_type idx) const;
constexpr reference front() const;
constexpr reference back() const;
constexpr pointer data() const noexcept;

// 24.7.2.2.7, iterator support
constexpr iterator begin() const noexcept;
constexpr iterator end() const noexcept;
constexpr const_iterator cbegin() const noexcept { return begin(); }
constexpr const_iterator cend() const noexcept { return end(); }
constexpr reverse_iterator rbegin() const noexcept;
constexpr reverse_iterator rend() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept { return rbegin(); }
constexpr const_reverse_iterator crend() const noexcept { return rend(); }

private:
    pointer data_;           // exposition only
    size_type size_;         // exposition only
};

template<class It, class EndOrSize>
    span(It, EndOrSize) -> span<remove_reference_t<iter_reference_t<It>>>;
template<class T, size_t N>
    span(T (&)[N]) -> span<T, N>;
template<class T, size_t N>
    span(array<T, N>&) -> span<T, N>;
template<class T, size_t N>
    span(const array<T, N>&) -> span<const T, N>;
template<class R>
    span(R&&) -> span<remove_reference_t<ranges::range_reference_t<R>>>;
}

```

`span<ElementType, Extent>` is a trivially copyable type (6.8.1).

`ElementType` is required to be a complete object type that is not an abstract class type.

24.7.2.2.2 Constructors, copy, and assignment

[span.cons]

```
constexpr span() noexcept;
```

Constraints: `Extent == dynamic_extent || Extent == 0` is true.

Postconditions: `size() == 0 && data() == nullptr`.

```
template<class It>
constexpr explicit(Extent != dynamic_extent) span(It first, size_type count);
```

Constraints: Let `U` be `remove_reference_t<iter_reference_t<It>>`.

- `It` satisfies `contiguous_iterator`.
- `is_convertible_v<U(*)[], element_type(*)[]>` is true.

NOTE 1 The intent is to allow only qualification conversions of the iterator reference type to `element_type`.

Preconditions:

- `[first, first + count)` is a valid range.
- `It` models `contiguous_iterator`.
- If `extent` is not equal to `dynamic_extent`, then `count` is equal to `extent`.

Effects: Initializes `data_` with `to_address(first)` and `size_` with `count`.

Throws: Nothing.

```
template<class It, class End>
constexpr explicit(Extent != dynamic_extent) span(It first, End last);
```

Constraints: Let `U` be `remove_reference_t<iter_reference_t<It>>`.

- `is_convertible_v<U(*)[], element_type(*)[]>` is true.

NOTE 2 The intent is to allow only qualification conversions of the iterator reference type to `element_type`.

- It satisfies `contiguous_iterator`.
- `End` satisfies `sized_sentinel_for<It>`.
- `is_convertible_v<End, size_t>` is false.

Preconditions:

- If `extent` is not equal to `dynamic_extent`, then `last - first` is equal to `extent`.
- `[first, last)` is a valid range.
- It models `contiguous_iterator`.
- `End` models `sized_sentinel_for<It>`.

Effects: Initializes `data_` with `to_address(first)` and `size_` with `last - first`.

Throws: When and what `last - first` throws.

```
template<size_t N> constexpr span(type_identity_t<element_type> (&arr)[N]) noexcept;
template<class T, size_t N> constexpr span(array<T, N>& arr) noexcept;
template<class T, size_t N> constexpr span(const array<T, N>& arr) noexcept;
```

Constraints: Let `U` be `remove_pointer_t<decltype(data(arr))>`.

- `extent == dynamic_extent || N == extent` is true, and
- `is_convertible_v<U(*)[], element_type(*)[]>` is true.

NOTE 3 The intent is to allow only qualification conversions of the array element type to `element_type`.

Effects: Constructs a `span` that is a view over the supplied array.

NOTE 4 `type_identity_t` affects class template argument deduction.

Postconditions: `size() == N && data() == data(arr)` is true.

```
template<class R> constexpr explicit(extent != dynamic_extent) span(R&& r);
```

Constraints: Let `U` be `remove_reference_t<ranges::range_reference_t<R>>`.

- `R` satisfies `ranges::contiguous_range` and `ranges::sized_range`.
- Either `R` satisfies `ranges::borrowed_range` or `is_const_v<element_type>` is true.
- `remove_cvref_t<R>` is not a specialization of `span`.
- `remove_cvref_t<R>` is not a specialization of `array`.
- `is_array_v<remove_cvref_t<R>>` is false.
- `is_convertible_v<U(*)[], element_type(*)[]>` is true.

NOTE 5 The intent is to allow only qualification conversions of the range reference type to `element_type`.

Preconditions:

- If `extent` is not equal to `dynamic_extent`, then `ranges::size(r)` is equal to `extent`.
- `R` models `ranges::contiguous_range` and `ranges::sized_range`.
- If `is_const_v<element_type>` is false, `R` models `ranges::borrowed_range`.

Effects: Initializes `data_` with `ranges::data(r)` and `size_` with `ranges::size(r)`.

Throws: What and when `ranges::data(r)` and `ranges::size(r)` throw.

```
constexpr span(const span& other) noexcept = default;
```

Postconditions: `other.size() == size() && other.data() == data()`.

```
template<class OtherElementType, size_t OtherExtent>
constexpr explicit(see below) span(const span<OtherElementType, OtherExtent>& s) noexcept;
```

Constraints:

- `extent == dynamic_extent || OtherExtent == dynamic_extent || extent == OtherExtent` is true, and

— `is_convertible_v<OtherElementType(*)[], element_type(*)[]>` is true.

NOTE 6 The intent is to allow only qualification conversions of the `OtherElementType` to `element_type`.

Preconditions: If `extent` is not equal to `dynamic_extent`, then `s.size()` is equal to `extent`.

Effects: Constructs a `span` that is a view over the range `[s.data(), s.data() + s.size())`.

Postconditions: `size() == s.size() && data() == s.data()`.

Remarks: The expression inside `explicit` is equivalent to:

```
extent != dynamic_extent && OtherExtent == dynamic_extent
```

```
constexpr span& operator=(const span& other) noexcept = default;
```

Postconditions: `size() == other.size() && data() == other.data()`.

24.7.2.2.3 Deduction guides

[span.deduct]

```
template<class It, class EndOrSize>
span(It, EndOrSize) -> span<remove_reference_t<iter_reference_t<It>>>;
```

Constraints: It satisfies `contiguous_iterator`.

```
template<class R>
span(R&&) -> span<remove_reference_t<ranges::range_reference_t<R>>>;
```

Constraints: R satisfies `ranges::contiguous_range`.

24.7.2.2.4 Subviews

[span.sub]

```
template<size_t Count> constexpr span<element_type, Count> first() const;
```

Mandates: `Count <= Extent` is true.

Preconditions: `Count <= size()` is true.

Effects: Equivalent to: `return R{data(), Count};` where R is the return type.

```
template<size_t Count> constexpr span<element_type, Count> last() const;
```

Mandates: `Count <= Extent` is true.

Preconditions: `Count <= size()` is true.

Effects: Equivalent to: `return R{data() + (size() - Count), Count};` where R is the return type.

```
template<size_t Offset, size_t Count = dynamic_extent>
constexpr span<element_type, see below> subspan() const;
```

Mandates:

`Offset <= Extent && (Count == dynamic_extent || Count <= Extent - Offset)`
is true.

Preconditions:

`Offset <= size() && (Count == dynamic_extent || Count <= size() - Offset)`
is true.

Effects: Equivalent to:

```
return span<ElementType, see below>(
    data() + Offset, Count != dynamic_extent ? Count : size() - Offset);
```

Remarks: The second template argument of the returned `span` type is:

```
Count != dynamic_extent ? Count
    : (Extent != dynamic_extent ? Extent - Offset
        : dynamic_extent)
```

```
constexpr span<element_type, dynamic_extent> first(size_type count) const;
```

Preconditions: `count <= size()` is true.

Effects: Equivalent to: `return {data(), count};`

```
constexpr span<element_type, dynamic_extent> last(size_type count) const;
```

Preconditions: `count <= size()` is true.

Effects: Equivalent to: `return {data() + (size() - count), count};`

```
constexpr span<element_type, dynamic_extent> subspan(
    size_type offset, size_type count = dynamic_extent) const;
```

Preconditions:

`offset <= size() && (count == dynamic_extent || count <= size() - offset)`

is true.

Effects: Equivalent to:

`return {data() + offset, count == dynamic_extent ? size() - offset : count};`

24.7.2.2.5 Observers

[span.obs]

```
constexpr size_type size() const noexcept;
```

Effects: Equivalent to: `return size_;`

```
constexpr size_type size_bytes() const noexcept;
```

Effects: Equivalent to: `return size() * sizeof(element_type);`

```
[[nodiscard]] constexpr bool empty() const noexcept;
```

Effects: Equivalent to: `return size() == 0;`

24.7.2.2.6 Element access

[span.elem]

```
constexpr reference operator[](size_type idx) const;
```

Preconditions: `idx < size()` is true.

Effects: Equivalent to: `return *(data() + idx);`

```
constexpr reference front() const;
```

Preconditions: `empty()` is false.

Effects: Equivalent to: `return *data();`

```
constexpr reference back() const;
```

Preconditions: `empty()` is false.

Effects: Equivalent to: `return *(data() + (size() - 1));`

```
constexpr pointer data() const noexcept;
```

Effects: Equivalent to: `return data_;`

24.7.2.2.7 Iterator support

[span.iterators]

```
using iterator = implementation-defined;
```

The type models `contiguous_iterator` (25.3.4.14), meets the *Cpp17RandomAccessIterator* requirements (25.3.5.7), and meets the requirements for `constexpr` iterators (25.3.1), whose value type is `value_type` and whose reference type is `reference`.

All requirements on container iterators (24.2.2.2) apply to `span::iterator` as well.

```
constexpr iterator begin() const noexcept;
```

Returns: An iterator referring to the first element in the span. If `empty()` is true, then it returns the same value as `end()`.

```
constexpr iterator end() const noexcept;
```

Returns: An iterator which is the past-the-end value.

```
constexpr reverse_iterator rbegin() const noexcept;
```

Effects: Equivalent to: `return reverse_iterator(end());`

```
constexpr reverse_iterator rend() const noexcept;
```

Effects: Equivalent to: `return reverse_iterator(begin());`

24.7.2.3 Views of object representation

[span.objectrep]

```
template<class ElementType, size_t Extent>
```

```
span<const byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
```

```
as_bytes(span<ElementType, Extent> s) noexcept;
```

Effects: Equivalent to: `return R{reinterpret_cast<const byte*>(s.data()), s.size_bytes()};` where `R` is the return type.

```
template<class ElementType, size_t Extent>
```

```
span<byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
```

```
as_writable_bytes(span<ElementType, Extent> s) noexcept;
```

Constraints: `is_const_v<ElementType>` is false.

Effects: Equivalent to: `return R{reinterpret_cast<byte*>(s.data()), s.size_bytes()};` where `R` is the return type.

24.7.3 Multidimensional access

[views.multidim]

24.7.3.1 Overview

[mdspan.overview]

A *multidimensional index space* is a Cartesian product of integer intervals. Each interval can be represented by a half-open range $[L_i, U_i)$, where L_i and U_i are the lower and upper bounds of the i^{th} dimension. The *rank* of a multidimensional index space is the number of intervals it represents. The *size of a multidimensional index space* is the product of $U_i - L_i$ for each dimension i if its rank is greater than 0, and 1 otherwise.

An integer r is a *rank index* of an index space S if r is in the range $[0, \text{rank of } S)$.

A pack of integers `idx` is a *multidimensional index* in a multidimensional index space S (or representation thereof) if both of the following are true:

- `sizeof...(idx)` is equal to the rank of S , and
- for every rank index i of S , the i^{th} value of `idx` is an integer in the interval $[L_i, U_i)$ of S .

24.7.3.2 Header `<mdspan>` synopsis

[mdspan.syn]

```
namespace std {
    // 24.7.3.3, class template extents
    template<class IndexType, size_t... Extents>
        class extents;

    // 24.7.3.3.6, alias template dextents
    template<class IndexType, size_t Rank>
        using dextents = see below;

    // 24.7.3.4, layout mapping
    struct layout_left;
    struct layout_right;
    struct layout_stride;

    // 24.7.3.5.3, class template default_accessor
    template<class ElementType>
        class default_accessor;

    // 24.7.3.6, class template mdspan
    template<class ElementType, class Extents, class LayoutPolicy = layout_right,
            class AccessorPolicy = default_accessor<ElementType>>
        class mdspan;
}
```

24.7.3.3 Class template extents

[mdspan.extents]

24.7.3.3.1 Overview

[mdspan.extents.overview]

The class template `extents` represents a multidimensional index space of rank equal to `sizeof...(Extents)`. In (24.7), `extents` is used synonymously with multidimensional index space.

```

namespace std {
    template<class IndexType, size_t... Extents>
    class extents {
    public:
        using index_type = IndexType;
        using size_type = make_unsigned_t<index_type>;
        using rank_type = size_t;

        // 24.7.3.3.4, observers of the multidimensional index space
        static constexpr rank_type rank() noexcept { return sizeof...(Extents); }
        static constexpr rank_type rank_dynamic() noexcept { return dynamic_index(rank()); }
        static constexpr size_t static_extent(rank_type) noexcept;
        constexpr index_type extent(rank_type) const noexcept;

        // 24.7.3.3.3, constructors
        constexpr extents() noexcept = default;

        template<class OtherIndexType, size_t... OtherExtents>
        constexpr explicit(see below)
            extents(const extents<OtherIndexType, OtherExtents...>&) noexcept;
        template<class... OtherIndexTypes>
        constexpr explicit extents(OtherIndexTypes...) noexcept;
        template<class OtherIndexType, size_t N>
        constexpr explicit(N != rank_dynamic())
            extents(span<OtherIndexType, N>) noexcept;
        template<class OtherIndexType, size_t N>
        constexpr explicit(N != rank_dynamic())
            extents(const array<OtherIndexType, N>&) noexcept;

        // 24.7.3.3.5, comparison operators
        template<class OtherIndexType, size_t... OtherExtents>
        friend constexpr bool operator==(const extents&,
            const extents<OtherIndexType, OtherExtents...>&) noexcept;

        // 24.7.3.3.2, exposition-only helpers
        constexpr size_t fwd-prod-of-extents(rank_type) const noexcept; // exposition only
        constexpr size_t rev-prod-of-extents(rank_type) const noexcept; // exposition only
        template<class OtherIndexType>
        static constexpr auto index-cast(OtherIndexType&&) noexcept; // exposition only

    private:
        static constexpr rank_type dynamic_index(rank_type) noexcept; // exposition only
        static constexpr rank_type dynamic_index_inv(rank_type) noexcept; // exposition only
        array<index_type, rank_dynamic()> dynamic_extents{}; // exposition only
    };

    template<class... Integrals>
    explicit extents(Integrals...)
        -> see below;
}

```

Mandates:

- `IndexType` is a signed or unsigned integer type, and
- each element of `Extents` is either equal to `dynamic_extent`, or is representable as a value of type `IndexType`.

Each specialization of `extents` models **regular** and is trivially copyable.

Let E_r be the r^{th} element of **Extents**. E_r is a *dynamic extent* if it is equal to **dynamic_extent**, otherwise E_r is a *static extent*. Let D_r be the value of **dynamic-extents** [**dynamic-index** (r)] if E_r is a dynamic extent, otherwise E_r .

The r^{th} interval of the multidimensional index space represented by an **extents** object is $[0, D_r)$.

24.7.3.3.2 Exposition-only helpers

[mdspan.extents.expo]

```
static constexpr rank_type dynamic-index(rank_type i) noexcept;
```

Preconditions: $i \leq \text{rank}()$ is true.

Returns: The number of E_r with $r < i$ for which E_r is a dynamic extent.

```
static constexpr rank_type dynamic-index-inv(rank_type i) noexcept;
```

Preconditions: $i < \text{rank\_dynamic}()$ is true.

Returns: The minimum value of r such that **dynamic-index** ($r + 1$) == $i + 1$ is true.

```
constexpr size_t fwd-prod-of-extents(rank_type i) const noexcept;
```

Preconditions: $i \leq \text{rank}()$ is true.

Returns: If $i > 0$ is true, the product of **extent** (k) for all k in the range $[0, i)$, otherwise 1.

```
constexpr size_t rev-prod-of-extents(rank_type i) const noexcept;
```

Preconditions: $i < \text{rank}()$ is true.

Returns: If $i + 1 < \text{rank}()$ is true, the product of **extent** (k) for all k in the range $[i + 1, \text{rank}())$, otherwise 1.

```
template<class OtherIndexType>
```

```
static constexpr auto index-cast(OtherIndexType&& i) noexcept;
```

Effects:

- If **OtherIndexType** is an integral type other than **bool**, then equivalent to **return i**;
- otherwise, equivalent to **return static_cast<index_type>(i)**;

NOTE This function will always return an integral type other than **bool**. Since this function's call sites are constrained on convertibility of **OtherIndexType** to **index_type**, integer-class types can use the **static_cast** branch without loss of precision.

24.7.3.3.3 Constructors

[mdspan.extents.cons]

```
template<class OtherIndexType, size_t... OtherExtents>
```

```
constexpr explicit(see below)
```

```
extents(const extents<OtherIndexType, OtherExtents...>& other) noexcept;
```

Constraints:

- **sizeof... (OtherExtents)** == **rank()** is true.
- **((OtherExtents == dynamic_extent || Extents == dynamic_extent || OtherExtents == Extents) && ...)** is true.

Preconditions:

- **other.extent** (r) equals E_r for each r for which E_r is a static extent, and
- either
 - **sizeof... (OtherExtents)** is zero, or
 - **other.extent** (r) is representable as a value of type **index_type** for every rank index r of **other**.

Postconditions: ***this == other** is true.

Remarks: The expression inside **explicit** is equivalent to:

```
((Extents != dynamic_extent) && (OtherExtents == dynamic_extent)) || ... ) ||
(numeric_limits<index_type>::max() < numeric_limits<OtherIndexType>::max())
```

```
template<class... OtherIndexTypes>
constexpr explicit extents(OtherIndexTypes... exts) noexcept;
```

Let N be `sizeof...(OtherIndexTypes)`, and let `exts_arr` be `array<index_type, N>{static_cast<index_type>(std::move(exts))...}`.

Constraints:

- `(is_convertible_v<OtherIndexTypes, index_type> && ...)` is true,
- `(is_nothrow_constructible_v<index_type, OtherIndexTypes> && ...)` is true, and
- `N == rank_dynamic() || N == rank()` is true.

NOTE One can construct `extents` from just dynamic extents, which are all the values getting stored, or from all the extents with a precondition.

Preconditions:

- If `N != rank_dynamic()` is true, `exts_arr[r]` equals E_r for each r for which E_r is a static extent, and
- either
 - `sizeof...(exts) == 0` is true, or
 - each element of `exts` is nonnegative and is representable as a value of type `index_type`.

Postconditions: `*this == extents(exts_arr)` is true.

```
template<class OtherIndexType, size_t N>
constexpr explicit(N != rank_dynamic())
    extents(span<OtherIndexType, N> exts) noexcept;
template<class OtherIndexType, size_t N>
constexpr explicit(N != rank_dynamic())
    extents(const array<OtherIndexType, N>& exts) noexcept;
```

Constraints:

- `is_convertible_v<const OtherIndexType&, index_type>` is true,
- `is_nothrow_constructible_v<index_type, const OtherIndexType&>` is true, and
- `N == rank_dynamic() || N == rank()` is true.

Preconditions:

- If `N != rank_dynamic()` is true, `exts[r]` equals E_r for each r for which E_r is a static extent, and
- either
 - N is zero, or
 - `exts[r]` is nonnegative and is representable as a value of type `index_type` for every rank index r .

Effects:

- If N equals `dynamic_rank()`, for all d in the range $[0, \text{rank\_dynamic}())$, direct-non-list-initializes `dynamic_extents[d]` with `as_const(exts[d])`.
- Otherwise, for all d in the range $[0, \text{rank\_dynamic}())$, direct-non-list-initializes `dynamic_extents[d]` with `as_const(exts[dynamic_index_inv(d)])`.

```
template<class... Integrals>
explicit extents(Integrals...) -> see below;
```

Constraints: `(is_convertible_v<Integrals, size_t> && ...)` is true.

Remarks: The deduced type is `dextents<size_t, sizeof...(Integrals)>`.

24.7.3.3.4 Observers of the multidimensional index space [mdspan.extents.obs]

```
static constexpr size_t static_extent(rank_type i) noexcept;
```

Preconditions: `i < rank()` is true.

Returns: E_i .

```
constexpr index_type extent(rank_type i) const noexcept;
```

Preconditions: $i < \text{rank}()$ is true.

Returns: D_i .

24.7.3.3.5 Comparison operators

[mdspan.extents.cmp]

```
template<class OtherIndexType, size_t... OtherExtents>
```

```
friend constexpr bool operator==(const extents& lhs,  
                                const extents<OtherIndexType, OtherExtents...& rhs) noexcept;
```

Returns: true if $\text{lhs.rank}()$ equals $\text{rhs.rank}()$ and if $\text{lhs.extent}(r)$ equals $\text{rhs.extent}(r)$ for every rank index r of rhs , otherwise false.

24.7.3.3.6 Alias template dextents

[mdspan.extents.dextents]

```
template<class IndexType, size_t Rank>
```

```
using dextents = see below;
```

Result: A type E that is a specialization of `extents` such that $E::\text{rank}() == \text{Rank}$ && $E::\text{rank}() == E::\text{rank\_dynamic}()$ is true, and $E::\text{index\_type}$ denotes `IndexType`.

24.7.3.4 Layout mapping

[mdspan.layout]

24.7.3.4.1 General

[mdspan.layout.general]

In 24.7.3.4.2 and 24.7.3.4.3:

- M denotes a layout mapping class.
- m denotes a (possibly const) value of type M .
- i and j are packs of (possibly const) integers that are multidimensional indices in $m.\text{extents}()$ (24.7.3.1).
NOTE The type of each element of the packs can be a different integer type.
- r is a (possibly const) rank index of `typename  $M::\text{extents\_type}$` .
- d_r is a pack of (possibly const) integers for which $\text{sizeof}...(d_r) == M::\text{extents\_type}::\text{rank}()$ is true, the r^{th} element is equal to 1, and all other elements are equal to 0.

In subclauses 24.7.3.4.2 through 24.7.3.4.7, let *is-mapping-of* be the exposition-only variable template defined as follows:

```
template<class Layout, class Mapping>  
constexpr bool is-mapping-of = // exposition only  
is_same_v<typename Layout::template mapping<typename Mapping::extents_type>, Mapping>;
```

24.7.3.4.2 Requirements

[mdspan.layout.reqmts]

A type M meets the *layout mapping* requirements if

- M models copyable and equality_comparable,
- `is_nothrow_move_constructible_v< $M$ >` is true,
- `is_nothrow_move_assignable_v< $M$ >` is true,
- `is_nothrow_swappable_v< $M$ >` is true, and
- the following types and expressions are well-formed and have the specified semantics.

```
typename  $M::\text{extents\_type}$ 
```

Result: A type that is a specialization of `extents`.

```
typename  $M::\text{index\_type}$ 
```

Result: `typename  $M::\text{extents\_type}::\text{index\_type}$` .

```
typename  $M::\text{rank\_type}$ 
```

Result: `typename  $M::\text{extents\_type}::\text{rank\_type}$` .

```
typename  $M::\text{layout\_type}$ 
```

Result: A type MP that meets the layout mapping policy requirements (24.7.3.4.3) and for which *is-mapping-of*< MP , M > is true.

`m.extents()`

Result: `const typename M::extents_type&`

`m(i...)`

Result: `typename M::index_type`

Returns: A nonnegative integer less than `numeric_limits<typename M::index_type>::max()` and less than or equal to `numeric_limits<size_t>::max()`.

`m(i...) == m(static_cast<typename M::index_type>(i)...)`

Result: `bool`

Returns: `true`

`m.required_span_size()`

Result: `typename M::index_type`

Returns: If the size of the multidimensional index space `m.extents()` is 0, then 0, else 1 plus the maximum value of `m(i...)` for all `i`.

`m.is_unique()`

Result: `bool`

Returns: `true` only if for every `i` and `j` where `(i != j || ...)` is `true`, `m(i...) != m(j...)` is `true`.

NOTE 1 A mapping can return `false` even if the condition is met. For certain layouts, it is possibly not feasible to determine efficiently whether the layout is unique.

`m.is_exhaustive()`

Result: `bool`

Returns: `true` only if for all `k` in the range `[0, m.required_span_size())` there exists an `i` such that `m(i...)` equals `k`.

NOTE 2 A mapping can return `false` even if the condition is met. For certain layouts, it is possibly not feasible to determine efficiently whether the layout is exhaustive.

`m.is_strided()`

Result: `bool`

Returns: `true` only if for every rank index `r` of `m.extents()` there exists an integer s_r such that, for all `i` where `(i + dr)` is a multidimensional index in `m.extents()` (24.7.3.1), `m((i + dr)...) - m(i...)` equals s_r .

NOTE 3 This implies that for a strided layout $m(i_0, \dots, i_k) = m(0, \dots, 0) + i_0 \times s_0 + \dots + i_k \times s_k$.

NOTE 4 A mapping can return `false` even if the condition is met. For certain layouts, it is possibly not feasible to determine efficiently whether the layout is strided.

`m.stride(r)`

Preconditions: `m.is_strided()` is `true`.

Result: `typename M::index_type`

Returns: s_r as defined in `m.is_strided()` above.

`M::is_always_unique()`

Result: A constant expression (7.7) of type `bool`.

Returns: `true` only if `m.is_unique()` is `true` for all possible objects `m` of type `M`.

NOTE 5 A mapping can return `false` even if the above condition is met. For certain layout mappings, it is possibly not feasible to determine whether every instance is unique.

`M::is_always_exhaustive()`

Result: A constant expression (7.7) of type `bool`.

Returns: `true` only if `m.is_exhaustive()` is `true` for all possible objects `m` of type `M`.

NOTE 6 A mapping can return **false** even if the above condition is met. For certain layout mappings, it is possibly not feasible to determine whether every instance is exhaustive.

`M::is_always_strided()`

Result: A constant expression (7.7) of type `bool`.

Returns: `true` only if `m.is_strided()` is `true` for all possible objects `m` of type `M`.

NOTE 7 A mapping can return **false** even if the above condition is met. For certain layout mappings, it is possibly not feasible to determine whether every instance is strided.

24.7.3.4.3 Layout mapping policy requirements [mdspan.layout.policy.reqmts]

A type `MP` meets the *layout mapping policy* requirements if for a type `E` that is a specialization of `extents`, `MP::mapping<E>` is valid and denotes a type `X` that meets the layout mapping requirements (24.7.3.4.2), and for which the *qualified-id* `X::layout_type` is valid and denotes the type `MP` and the *qualified-id* `X::extents_type` denotes `E`.

24.7.3.4.4 Layout mapping policies [mdspan.layout.policy.overview]

```
namespace std {
    struct layout_left {
        template<class Extents>
        class mapping;
    };
    struct layout_right {
        template<class Extents>
        class mapping;
    };
    struct layout_stride {
        template<class Extents>
        class mapping;
    };
}
```

Each of `layout_left`, `layout_right`, and `layout_stride` meets the layout mapping policy requirements and is a trivial type.

24.7.3.4.5 Class template `layout_left::mapping` [mdspan.layout.left]

24.7.3.4.5.1 Overview [mdspan.layout.left.overview]

`layout_left` provides a layout mapping where the leftmost extent has stride 1, and strides increase left-to-right as the product of extents.

```
namespace std {
    template<class Extents>
    class layout_left::mapping {
    public:
        using extents_type = Extents;
        using index_type = typename extents_type::index_type;
        using size_type = typename extents_type::size_type;
        using rank_type = typename extents_type::rank_type;
        using layout_type = layout_left;

        // 24.7.3.4.5.2, constructors
        constexpr mapping() noexcept = default;
        constexpr mapping(const mapping&) noexcept = default;
        constexpr mapping(const extents_type&) noexcept;
        template<class OtherExtents>
        constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
            mapping(const mapping<OtherExtents>&) noexcept;
        template<class OtherExtents>
        constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
            mapping(const layout_right::mapping<OtherExtents>&) noexcept;
        template<class OtherExtents>
        constexpr explicit(extents_type::rank() > 0)
            mapping(const layout_stride::mapping<OtherExtents>&);
    };
}
```

```
constexpr mapping& operator=(const mapping&) noexcept = default;

// 24.7.3.4.5.3, observers
constexpr const extents_type& extents() const noexcept { return extents_; }

constexpr index_type required_span_size() const noexcept;

template<class... Indices>
    constexpr index_type operator()(Indices...) const noexcept;

static constexpr bool is_always_unique() noexcept { return true; }
static constexpr bool is_always_exhaustive() noexcept { return true; }
static constexpr bool is_always_strided() noexcept { return true; }

static constexpr bool is_unique() noexcept { return true; }
static constexpr bool is_exhaustive() noexcept { return true; }
static constexpr bool is_strided() noexcept { return true; }

constexpr index_type stride(rank_type) const noexcept;

template<class OtherExtents>
    friend constexpr bool operator==(const mapping&, const mapping<OtherExtents>&) noexcept;

private:
    extents_type extents_{};    // exposition only
};
}
```

If `Extents` is not a specialization of `extents`, then the program is ill-formed.

`layout_left::mapping<E>` is a trivially copyable type that models `regular` for each `E`.

Mandates: If `Extents::rank_dynamic() == 0` is true, then the size of the multidimensional index space `Extents()` is representable as a value of type `typename Extents::index_type`.

24.7.3.4.5.2 Constructors

[mdspan.layout.left.cons]

```
constexpr mapping(const extents_type& e) noexcept;
```

Preconditions: The size of the multidimensional index space `e` is representable as a value of type `index_type` (6.8.2).

Effects: Direct-non-list-initializes `extents_` with `e`.

```
template<class OtherExtents>
constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
    mapping(const mapping<OtherExtents>& other) noexcept;
```

Constraints: `is_constructible_v<extents_type, OtherExtents>` is true.

Preconditions: `other.required_span_size()` is representable as a value of type `index_type` (6.8.2).

Effects: Direct-non-list-initializes `extents_` with `other.extents()`.

```
template<class OtherExtents>
constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
    mapping(const layout_right::mapping<OtherExtents>& other) noexcept;
```

Constraints:

- `extents_type::rank() <= 1` is true, and
- `is_constructible_v<extents_type, OtherExtents>` is true.

Preconditions: `other.required_span_size()` is representable as a value of type `index_type` (6.8.2).

Effects: Direct-non-list-initializes `extents_` with `other.extents()`.

```
template<class OtherExtents>
```

```
constexpr explicit(extents_type::rank() > 0)
```

```
mapping(const layout_stride::mapping<OtherExtents>& other);
```

Constraints: `is_constructible_v<extents_type, OtherExtents>` is true.

Preconditions:

- If `extents_type::rank() > 0` is true, then for all r in the range $[0, \text{extents\_type::rank}())$, `other.stride(r)` equals `other.extents().fwd-prod-of-extents(r)`, and
- `other.required_span_size()` is representable as a value of type `index_type` (6.8.2).

Effects: Direct-non-list-initializes `extents_` with `other.extents()`.

24.7.3.4.5.3 Observers

[mdspan.layout.left.obs]

```
constexpr index_type required_span_size() const noexcept;
```

Returns: `extents().fwd-prod-of-extents(extents_type::rank())`.

```
template<class... Indices>
```

```
constexpr index_type operator()(Indices... i) const noexcept;
```

Constraints:

- `sizeof...(Indices) == extents_type::rank()` is true,
- `(is_convertible_v<Indices, index_type> && ...)` is true, and
- `(is_nothrow_constructible_v<index_type, Indices> && ...)` is true.

Preconditions: `extents_type::index-cast(i)` is a multidimensional index in `extents_` (24.7.3.1).

Effects: Let P be a parameter pack such that

```
is_same_v<index_sequence_for<Indices...>, index_sequence<P...>>
```

is true. Equivalent to:

```
return ((static_cast<index_type>(i) * stride(P)) + ... + 0);
```

```
constexpr index_type stride(rank_type i) const;
```

Constraints: `extents_type::rank() > 0` is true.

Preconditions: `i < extents_type::rank()` is true.

Returns: `extents().fwd-prod-of-extents(i)`.

```
template<class OtherExtents>
```

```
friend constexpr bool operator==(const mapping& x, const mapping<OtherExtents>& y) noexcept;
```

Constraints: `extents_type::rank() == OtherExtents::rank()` is true.

Effects: Equivalent to: `return x.extents() == y.extents();`

24.7.3.4.6 Class template `layout_right::mapping`

[mdspan.layout.right]

24.7.3.4.6.1 Overview

[mdspan.layout.right.overview]

`layout_right` provides a layout mapping where the rightmost extent is stride 1, and strides increase right-to-left as the product of extents.

```
namespace std {
```

```
template<class Extents>
```

```
class layout_right::mapping {
```

```
public:
```

```
using extents_type = Extents;
```

```
using index_type = typename extents_type::index_type;
```

```
using size_type = typename extents_type::size_type;
```

```
using rank_type = typename extents_type::rank_type;
```

```
using layout_type = layout_right;
```

```
// 24.7.3.4.6.2, constructors
```

```
constexpr mapping() noexcept = default;
```

```
constexpr mapping(const mapping&) noexcept = default;
```

```

constexpr mapping(const extents_type&) noexcept;
template<class OtherExtents>
    constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
        mapping(const mapping<OtherExtents>&) noexcept;
template<class OtherExtents>
    constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
        mapping(const layout_left::mapping<OtherExtents>&) noexcept;
template<class OtherExtents>
    constexpr explicit(extents_type::rank() > 0)
        mapping(const layout_stride::mapping<OtherExtents>&) noexcept;

constexpr mapping& operator=(const mapping&) noexcept = default;

// 24.7.3.4.6.3, observers
constexpr const extents_type& extents() const noexcept { return extents_; }

constexpr index_type required_span_size() const noexcept;

template<class... Indices>
    constexpr index_type operator()(Indices...) const noexcept;

static constexpr bool is_always_unique() noexcept { return true; }
static constexpr bool is_always_exhaustive() noexcept { return true; }
static constexpr bool is_always_strided() noexcept { return true; }

static constexpr bool is_unique() noexcept { return true; }
static constexpr bool is_exhaustive() noexcept { return true; }
static constexpr bool is_strided() noexcept { return true; }

constexpr index_type stride(rank_type) const noexcept;

template<class OtherExtents>
    friend constexpr bool operator==(const mapping&, const mapping<OtherExtents>&) noexcept;

private:
    extents_type extents_{};    // exposition only
};

```

If `Extents` is not a specialization of `extents`, then the program is ill-formed.

`layout_right::mapping<E>` is a trivially copyable type that models `regular` for each `E`.

Mandates: If `Extents::rank_dynamic() == 0` is true, then the size of the multidimensional index space `Extents()` is representable as a value of type `typename Extents::index_type`.

24.7.3.4.6.2 Constructors

[mdspan.layout.right.cons]

```
constexpr mapping(const extents_type& e) noexcept;
```

Preconditions: The size of the multidimensional index space `e` is representable as a value of type `index_type` (6.8.2).

Effects: Direct-non-list-initializes `extents_` with `e`.

```

template<class OtherExtents>
    constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
        mapping(const mapping<OtherExtents>& other) noexcept;

```

Constraints: `is_constructible_v<extents_type, OtherExtents>` is true.

Preconditions: `other.required_span_size()` is representable as a value of type `index_type` (6.8.2).

Effects: Direct-non-list-initializes `extents_` with `other.extents()`.

```
template<class OtherExtents>
constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
mapping(const layout_left::mapping<OtherExtents>& other) noexcept;
```

Constraints:

- `extents_type::rank() <= 1` is true, and
- `is_constructible_v<extents_type, OtherExtents>` is true.

Preconditions: `other.required_span_size()` is representable as a value of type `index_type` (6.8.2).

Effects: Direct-non-list-initializes `extents_` with `other.extents()`.

```
template<class OtherExtents>
constexpr explicit(extents_type::rank() > 0)
mapping(const layout_stride::mapping<OtherExtents>& other) noexcept;
```

Constraints: `is_constructible_v<extents_type, OtherExtents>` is true.

Preconditions:

- If `extents_type::rank() > 0` is true, then for all r in the range $[0, \text{extents\_type::rank}())$, `other.stride(r)` equals `other.extents().rev-prod-of-extents(r)`.
- `other.required_span_size()` is representable as a value of type `index_type` (6.8.2).

Effects: Direct-non-list-initializes `extents_` with `other.extents()`.

24.7.3.4.6.3 Observers

[mdspan.layout.right.obs]

```
index_type required_span_size() const noexcept;
```

Returns: `extents().fwd-prod-of-extents(extents_type::rank())`.

```
template<class... Indices>
constexpr index_type operator()(Indices... i) const noexcept;
```

Constraints:

- `sizeof...(Indices) == extents_type::rank()` is true,
- `(is_convertible_v<Indices, index_type> && ...)` is true, and
- `(is_nothrow_constructible_v<index_type, Indices> && ...)` is true.

Preconditions: `extents_type::index-cast(i)` is a multidimensional index in `extents_` (24.7.3.1).

Effects: Let P be a parameter pack such that

```
is_same_v<index_sequence_for<Indices...>, index_sequence<P...>>
```

is true. Equivalent to:

```
return ((static_cast<index_type>(i) * stride(P)) + ... + 0);
```

```
constexpr index_type stride(rank_type i) const noexcept;
```

Constraints: `extents_type::rank() > 0` is true.

Preconditions: `i < extents_type::rank()` is true.

Returns: `extents().rev-prod-of-extents(i)`.

```
template<class OtherExtents>
friend constexpr bool operator==(const mapping& x, const mapping<OtherExtents>& y) noexcept;
```

Constraints: `extents_type::rank() == OtherExtents::rank()` is true.

Effects: Equivalent to: `return x.extents() == y.extents();`

24.7.3.4.7 Class template `layout_stride::mapping`

[mdspan.layout.stride]

24.7.3.4.7.1 Overview

[mdspan.layout.stride.overview]

`layout_stride` provides a layout mapping where the strides are user-defined.

```

namespace std {
    template<class Extents>
    class layout_stride::mapping {
    public:
        using extents_type = Extents;
        using index_type = typename extents_type::index_type;
        using size_type = typename extents_type::size_type;
        using rank_type = typename extents_type::rank_type;
        using layout_type = layout_stride;

    private:
        static constexpr rank_type rank_ = extents_type::rank();    // exposition only

    public:
        // 24.7.3.4.7.3, constructors
        constexpr mapping() noexcept;
        constexpr mapping(const mapping&) noexcept = default;
        template<class OtherIndexType>
            constexpr mapping(const extents_type&, span<OtherIndexType, rank_>) noexcept;
        template<class OtherIndexType>
            constexpr mapping(const extents_type&, const array<OtherIndexType, rank_>&) noexcept;

        template<class StridedLayoutMapping>
            constexpr explicit(see below) mapping(const StridedLayoutMapping&) noexcept;

        constexpr mapping& operator=(const mapping&) noexcept = default;

        // 24.7.3.4.7.4, observers
        constexpr const extents_type& extents() const noexcept { return extents_; }
        constexpr array<index_type, rank_> strides() const noexcept { return strides_; }

        constexpr index_type required_span_size() const noexcept;

        template<class... Indices>
            constexpr index_type operator()(Indices...) const noexcept;

        static constexpr bool is_always_unique() noexcept { return true; }
        static constexpr bool is_always_exhaustive() noexcept { return false; }
        static constexpr bool is_always_strided() noexcept { return true; }

        static constexpr bool is_unique() noexcept { return true; }
        constexpr bool is_exhaustive() const noexcept;
        static constexpr bool is_strided() noexcept { return true; }

        constexpr index_type stride(rank_type i) const noexcept { return strides_[i]; }

        template<class OtherMapping>
            friend constexpr bool operator==(const mapping&, const OtherMapping&) noexcept;

    private:
        extents_type extents_{};    // exposition only
        array<index_type, rank_> strides_{};    // exposition only
    };
}

```

If `Extents` is not a specialization of `extents`, then the program is ill-formed.

`layout_stride::mapping<E>` is a trivially copyable type that models **regular** for each `E`.

Mandates: If `Extents::rank_dynamic() == 0` is true, then the size of the multidimensional index space `Extents()` is representable as a value of type `typename Extents::index_type`.

24.7.3.4.7.2 Exposition-only helpers

[mdspan.layout.stride.expo]

Let *REQUIRED-SPAN-SIZE*(*e*, *strides*) be:

- 1, if `e.rank() == 0` is true,

- otherwise 0, if the size of the multidimensional index space **e** is 0,
- otherwise 1 plus the sum of products of (**e.extent**(*r*) - 1) and **strides**[*r*] for all *r* in the range [0, **e.rank**()).

Let **OFFSET**(**m**) be:

- **m**(), if **e.rank**() == 0 is true,
- otherwise 0, if the size of the multidimensional index space **e** is 0,
- otherwise **m**(**z**...) for a pack of integers **z** that is a multidimensional index in **m.extents**() and each element of **z** equals 0.

Let **is-extents** be the exposition-only variable template defined as follows:

```
template<class T>
    constexpr bool is-extents = false; // exposition only
template<class IndexType, size_t... Args>
    constexpr bool is-extents<extents<IndexType, Args...>> = true; // exposition only
```

Let **layout-mapping-alike** be the exposition-only concept defined as follows:

```
template<class M>
concept layout-mapping-alike = requires { // exposition only
    requires is-extents<typename M::extents_type>;
    { M::is_always_strided() } -> same_as<bool>;
    { M::is_always_exhaustive() } -> same_as<bool>;
    { M::is_always_unique() } -> same_as<bool>;
    bool_constant<M::is_always_strided()>::value;
    bool_constant<M::is_always_exhaustive()>::value;
    bool_constant<M::is_always_unique()>::value;
};
```

NOTE This concept checks that the functions **M::is_always_strided**(), **M::is_always_exhaustive**(), and **M::is_always_unique**() exist, are constant expressions, and have a return type of **bool**.

24.7.3.4.7.3 Constructors

[mdspan.layout.stride.cons]

constexpr mapping() noexcept;

Preconditions: **layout_right::mapping<extents_type>().required_span_size()** is representable as a value of type **index_type** (6.8.2).

Effects: Direct-non-list-initializes **extents_** with **extents_type()**, and for all *d* in the range [0, **rank_**), direct-non-list-initializes **strides_**[*d*] with **layout_right::mapping<extents_type>().stride**(*d*).

```
template<class OtherIndexType>
    constexpr mapping(const extents_type& e, span<OtherIndexType, rank_> s) noexcept;
template<class OtherIndexType>
    constexpr mapping(const extents_type& e, const array<OtherIndexType, rank_>& s) noexcept;
```

Constraints:

- **is_convertible_v<const OtherIndexType&, index_type>** is true, and
- **is_nothrow_constructible_v<index_type, const OtherIndexType&>** is true.

Preconditions:

- **s**[*i*] > 0 is true for all *i* in the range [0, **rank_**).
- **REQUIRED-SPAN-SIZE**(**e**, **s**) is representable as a value of type **index_type** (6.8.2).
- If **rank_** is greater than 0, then there exists a permutation *P* of the integers in the range [0, **rank_**), such that **s**[*p_i*] >= **s**[*p_{i-1}*] * **e.extent**(*p_{i-1}*) is true for all *i* in the range [1, **rank_**), where *p_i* is the *i*th element of *P*.

NOTE For **layout_stride**, this condition is necessary and sufficient for **is_unique**() to be true.

Effects: Direct-non-list-initializes **extents_** with **e**, and for all *d* in the range [0, **rank_**), direct-non-list-initializes **strides_**[*d*] with **as_const**(**s**[*d*]).

```
template<class StridedLayoutMapping>
constexpr explicit(see below)
mapping(const StridedLayoutMapping& other) noexcept;
```

Constraints:

- *layout-mapping-alike*<StridedLayoutMapping> is satisfied.
- `is_constructible_v<extents_type, typename StridedLayoutMapping::extents_type>` is true.
- `StridedLayoutMapping::is_always_unique()` is true.
- `StridedLayoutMapping::is_always_strided()` is true.

Preconditions:

- `StridedLayoutMapping` meets the layout mapping requirements (24.7.3.4.3),
- `other.stride(r) > 0` is true for every rank index r of `extents()`,
- `other.required_span_size()` is representable as a value of type `index_type` (6.8.2), and
- `OFFSET(other) == 0` is true.

Effects: Direct-non-list-initializes `extents_` with `other.extents()`, and for all d in the range $[0, rank_)$, direct-non-list-initializes `strides_[d]` with `other.stride(d)`.

Remarks: The expression inside `explicit` is equivalent to:

```
!(is_convertible_v<typename StridedLayoutMapping::extents_type, extents_type> &&
(is-mapping-of<layout_left, LayoutStrideMapping> ||
 is-mapping-of<layout_right, LayoutStrideMapping> ||
 is-mapping-of<layout_stride, LayoutStrideMapping>))
```

24.7.3.4.7.4 Observers

[mdspan.layout.stride.obs]

```
constexpr index_type required_span_size() const noexcept;
```

Returns: `REQUIRED-SPAN-SIZE(extents(), strides_)`.

```
template<class... Indices>
constexpr index_type operator()(Indices... i) const noexcept;
```

Constraints:

- `sizeof...(Indices) == rank_` is true,
- `(is_convertible_v<Indices, index_type> && ...)` is true, and
- `(is_nothrow_constructible_v<index_type, Indices> && ...)` is true.

Preconditions: `extents_type::index-cast(i)` is a multidimensional index in `extents_` (24.7.3.1).

Effects: Let P be a parameter pack such that

```
is_same_v<index_sequence_for<Indices...>, index_sequence<P...>>
```

is true. Equivalent to:

```
return ((static_cast<index_type>(i) * stride(P)) + ... + 0);
```

```
constexpr bool is_exhaustive() const noexcept;
```

Returns:

- true if `rank_` is 0.
- Otherwise, true if there is a permutation P of the integers in the range $[0, rank_)$ such that `stride( $p_0$ )` equals 1, and `stride( $p_i$ )` equals `stride( $p_{i-1}$ ) * extents().extent( $p_{i-1}$ )` for i in the range $[1, rank_)$, where p_i is the i^{th} element of P .
- Otherwise, false.

```
template<class OtherMapping>
friend constexpr bool operator==(const mapping& x, const OtherMapping& y) noexcept;
```

Constraints:

- *layout-mapping-alike*<OtherMapping> is satisfied.

- `rank_ == OtherMapping::extents_type::rank()` is true.
- `OtherMapping::is_always_strided()` is true.

Preconditions: `OtherMapping` meets the layout mapping requirements (24.7.3.4.3).

Returns: true if `x.extents() == y.extents()` is true, `OFFSET(y) == 0` is true, and each of `x.stride(r) == y.stride(r)` is true for `r` in the range `[0, x.extents().rank())`. Otherwise, false.

24.7.3.5 Accessor policy

[mdspan.accessor]

24.7.3.5.1 General

[mdspan.accessor.general]

An *accessor policy* defines types and operations by which a reference to a single object is created from an abstract data handle to a number of such objects and an index.

A range of indices `[0, N)` is an *accessible range* of a given data handle and an accessor if, for each `i` in the range, the accessor policy's `access` function produces a valid reference to an object.

In subclause 24.7.3.5.2,

- `A` denotes an accessor policy.
- `a` denotes a value of type `A` or `const A`.
- `p` denotes a value of type `A::data_handle_type` or `const A::data_handle_type`.
NOTE The type `A::data_handle_type` need not be dereferenceable.
- `n`, `i`, and `j` each denote values of type `size_t`.

24.7.3.5.2 Requirements

[mdspan.accessor.reqmts]

A type `A` meets the accessor policy requirements if

- `A` models copyable,
- `is_nothrow_move_constructible_v<A>` is true,
- `is_nothrow_move_assignable_v<A>` is true,
- `is_nothrow_swappable_v<A>` is true, and
- the following types and expressions are well-formed and have the specified semantics.

typename `A::element_type`

Result: A complete object type that is not an abstract class type.

typename `A::data_handle_type`

Result: A type that models copyable, and for which `is_nothrow_move_constructible_v<A::data_handle_type>` is true, `is_nothrow_move_assignable_v<A::data_handle_type>` is true, and `is_nothrow_swappable_v<A::data_handle_type>` is true.

NOTE 1 The type of `data_handle_type` need not be `element_type*`.

typename `A::reference`

Result: A type that models `common_reference_with<A::reference&&, A::element_type&>`.

NOTE 2 The type of `reference` need not be `element_type&`.

typename `A::offset_policy`

Result: A type `OP` such that:

- `OP` meets the accessor policy requirements,
- `constructible_from<OP, const A&>` is modeled, and
- `is_same_v<typename OP::element_type, typename A::element_type>` is true.

`a.access(p, i)`

Result: `A::reference`

Remarks: The expression is equality preserving.

NOTE 3 Concrete accessor policies can impose preconditions for their `access` function. However, it is possible that they do not. For example, an accessor where `p` is `span<A::element_type, dynamic_extent>` and `access(p, i)` returns `p[i % p.size()]` does not need to impose a precondition on `i`.

`a.offset(p, i)`

Result: `A::offset_policy::data_handle_type`

Returns: `q` such that for `b` being `A::offset_policy(a)`, and any integer `n` for which `[0, n)` is an accessible range of `p` and `a`:

- `[0, n - i)` is an accessible range of `q` and `b`; and
- `b.access(q, j)` provides access to the same element as `a.access(p, i + j)`, for every `j` in the range `[0, n - i)`.

Remarks: The expression is equality-preserving.

24.7.3.5.3 Class template `default_accessor`

[mdspan.accessor.default]

24.7.3.5.3.1 Overview

[mdspan.accessor.default.overview]

```
namespace std {
    template<class ElementType>
    struct default_accessor {
        using offset_policy = default_accessor;
        using element_type = ElementType;
        using reference = ElementType&;
        using data_handle_type = ElementType*;

        constexpr default_accessor() noexcept = default;
        template<class OtherElementType>
        constexpr default_accessor(default_accessor<OtherElementType>) noexcept;
        constexpr reference access(data_handle_type p, size_t i) const noexcept;
        constexpr data_handle_type offset(data_handle_type p, size_t i) const noexcept;
    };
}
```

`default_accessor` meets the accessor policy requirements.

`ElementType` is required to be a complete object type that is neither an abstract class type nor an array type.

Each specialization of `default_accessor` is a trivially copyable type that models `semiregular`.

`[0, n)` is an accessible range for an object `p` of type `data_handle_type` and an object of type `default_accessor` if and only if `[p, p + n)` is a valid range.

24.7.3.5.3.2 Members

[mdspan.accessor.default.members]

```
template<class OtherElementType>
constexpr default_accessor(default_accessor<OtherElementType>) noexcept {}

Constraints: is_convertible_v<OtherElementType(*)[], element_type(*)[]> is true.

constexpr reference access(data_handle_type p, size_t i) const noexcept;

Effects: Equivalent to: return p[i];

constexpr data_handle_type offset(data_handle_type p, size_t i) const noexcept;

Effects: Equivalent to: return p + i;
```

24.7.3.6 Class template `mdspan`

[mdspan.mdspan]

24.7.3.6.1 Overview

[mdspan.mdspan.overview]

`mdspan` is a view of a multidimensional array of elements.

```
namespace std {
    template<class ElementType, class Extents, class LayoutPolicy = layout_right,
            class AccessorPolicy = default_accessor<ElementType>>
    class mdspan {
    public:
        using extents_type = Extents;
```

```

using layout_type = LayoutPolicy;
using accessor_type = AccessorPolicy;
using mapping_type = typename layout_type::template mapping<extents_type>;
using element_type = ElementType;
using value_type = remove_cv_t<element_type>;
using index_type = typename extents_type::index_type;
using size_type = typename extents_type::size_type;
using rank_type = typename extents_type::rank_type;
using data_handle_type = typename accessor_type::data_handle_type;
using reference = typename accessor_type::reference;

static constexpr rank_type rank() noexcept { return extents_type::rank(); }
static constexpr rank_type rank_dynamic() noexcept { return extents_type::rank_dynamic(); }
static constexpr size_t static_extent(rank_type r) noexcept
    { return extents_type::static_extent(r); }
constexpr index_type extent(rank_type r) const noexcept { return extents().extent(r); }

// 24.7.3.6.2, constructors
constexpr mdspan();
constexpr mdspan(const mdspan& rhs) = default;
constexpr mdspan(mdspan&& rhs) = default;

template<class... OtherIndexTypes>
    constexpr explicit mdspan(data_handle_type ptr, OtherIndexTypes... exts);
template<class OtherIndexType, size_t N>
    constexpr explicit(N != rank_dynamic())
        mdspan(data_handle_type p, span<OtherIndexType, N> exts);
template<class OtherIndexType, size_t N>
    constexpr explicit(N != rank_dynamic())
        mdspan(data_handle_type p, const array<OtherIndexType, N>& exts);
constexpr mdspan(data_handle_type p, const extents_type& ext);
constexpr mdspan(data_handle_type p, const mapping_type& m);
constexpr mdspan(data_handle_type p, const mapping_type& m, const accessor_type& a);

template<class OtherElementType, class OtherExtents,
        class OtherLayoutPolicy, class OtherAccessorPolicy>
    constexpr explicit(see below)
        mdspan(const mdspan<OtherElementType, OtherExtents,
            OtherLayoutPolicy, OtherAccessorPolicy>& other);

constexpr mdspan& operator=(const mdspan& rhs) = default;

mdspan(const typename AccessorType::data_handle_type&, const MappingType&,
    const AccessorType&)
    -> mdspan<typename AccessorType::element_type, typename MappingType::extents_type,
        typename MappingType::layout_type, AccessorType>;
}

```

Mandates:

- `ElementType` is a complete object type that is neither an abstract class type nor an array type,
- `Extents` is a specialization of `extents`, and
- `is_same_v<ElementType, typename AccessorPolicy::element_type>` is true.

LayoutPolicy shall meet the layout mapping policy requirements (24.7.3.4.3), and AccessorPolicy shall meet the accessor policy requirements (24.7.3.5.2).

Each specialization MDS of mdspan models copyable and

- is_nothrow_move_constructible_v<MDS> is true,
- is_nothrow_move_assignable_v<MDS> is true, and
- is_nothrow_swappable_v<MDS> is true.

A specialization of mdspan is a trivially copyable type if its accessor_type, mapping_type, and data_handle_type are trivially copyable types.

24.7.3.6.2 Constructors

[mdspan.mdspan.cons]

```
constexpr mdspan();
```

Constraints:

- rank_dynamic() > 0 is true.
- is_default_constructible_v<data_handle_type> is true.
- is_default_constructible_v<mapping_type> is true.
- is_default_constructible_v<accessor_type> is true.

Preconditions: [0, map_.required_span_size()) is an accessible range of ptr_ and acc_ for the values of map_ and acc_ after the invocation of this constructor.

Effects: Value-initializes ptr_, map_, and acc_.

```
template<class... OtherIndexTypes>
```

```
constexpr explicit mdspan(data_handle_type p, OtherIndexTypes... exts);
```

Let N be sizeof...(OtherIndexTypes).

Constraints:

- (is_convertible_v<OtherIndexTypes, index_type> && ...) is true,
- (is_nothrow_constructible<index_type, OtherIndexTypes> && ...) is true,
- N == rank() || N == rank_dynamic() is true,
- is_constructible_v<mapping_type, extents_type> is true, and
- is_default_constructible_v<accessor_type> is true.

Preconditions: [0, map_.required_span_size()) is an accessible range of p and acc_ for the values of map_ and acc_ after the invocation of this constructor.

Effects:

- Direct-non-list-initializes ptr_ with std::move(p),
- direct-non-list-initializes map_ with extents_type(static_cast<index_type>(std::move(exts))...), and
- value-initializes acc_.

```
template<class OtherIndexType, size_t N>
```

```
constexpr explicit(N != rank_dynamic())
```

```
mdspan(data_handle_type p, span<OtherIndexType, N> exts);
```

```
template<class OtherIndexType, size_t N>
```

```
constexpr explicit(N != rank_dynamic())
```

```
mdspan(data_handle_type p, const array<OtherIndexType, N>& exts);
```

Constraints:

- is_convertible_v<const OtherIndexType&, index_type> is true,
- (is_nothrow_constructible<index_type, const OtherIndexType&> && ...) is true,
- N == rank() || N == rank_dynamic() is true,
- is_constructible_v<mapping_type, extents_type> is true, and
- is_default_constructible_v<accessor_type> is true.

Preconditions: `[0, map_.required_span_size())` is an accessible range of `p` and `acc_` for the values of `map_` and `acc_` after the invocation of this constructor.

Effects:

- Direct-non-list-initializes `ptr_` with `std::move(p)`,
- direct-non-list-initializes `map_` with `extents_type(exts)`, and
- value-initializes `acc_`.

```
constexpr mdspan(data_handle_type p, const extents_type& ext);
```

Constraints:

- `is_constructible_v<mapping_type, const extents_type&>` is true, and
- `is_default_constructible_v<accessor_type>` is true.

Preconditions: `[0, map_.required_span_size())` is an accessible range of `p` and `acc_` for the values of `map_` and `acc_` after the invocation of this constructor.

Effects:

- Direct-non-list-initializes `ptr_` with `std::move(p)`,
- direct-non-list-initializes `map_` with `ext`, and
- value-initializes `acc_`.

```
constexpr mdspan(data_handle_type p, const mapping_type& m);
```

Constraints: `is_default_constructible_v<accessor_type>` is true.

Preconditions: `[0, m.required_span_size())` is an accessible range of `p` and `acc_` for the value of `acc_` after the invocation of this constructor.

Effects:

- Direct-non-list-initializes `ptr_` with `std::move(p)`,
- direct-non-list-initializes `map_` with `m`, and
- value-initializes `acc_`.

```
constexpr mdspan(data_handle_type p, const mapping_type& m, const accessor_type& a);
```

Preconditions: `[0, m.required_span_size())` is an accessible range of `p` and `a`.

Effects:

- Direct-non-list-initializes `ptr_` with `std::move(p)`,
- direct-non-list-initializes `map_` with `m`, and
- direct-non-list-initializes `acc_` with `a`.

```
template<class OtherElementType, class OtherExtents,
        class OtherLayoutPolicy, class OtherAccessor>
constexpr explicit(see below)
mdspan(const mdspan<OtherElementType, OtherExtents,
                OtherLayoutPolicy, OtherAccessor>& other);
```

Constraints:

- `is_constructible_v<mapping_type, const OtherLayoutPolicy::template mapping<OtherExtents>&>` is true, and
- `is_constructible_v<accessor_type, const OtherAccessor&>` is true.

Mandates:

- `is_constructible_v<data_handle_type, const OtherAccessor::data_handle_type&>` is true, and
- `is_constructible_v<extents_type, OtherExtents>` is true.

Preconditions:

- For each rank index *r* of `extents_type`, `static_extent(r) == dynamic_extent || static_extent(r) == other.extent(r)` is true.
- `[0, map_.required_span_size())` is an accessible range of *ptr_* and *acc_* for values of *ptr_*, *map_*, and *acc_* after the invocation of this constructor.

Effects:

- Direct-non-list-initializes *ptr_* with `other.ptr_`,
- direct-non-list-initializes *map_* with `other.map_`, and
- direct-non-list-initializes *acc_* with `other.acc_`.

Remarks: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<const OtherLayoutPolicy::template mapping<OtherExtents>&, mapping_type>
|| !is_convertible_v<const OtherAccessor&, accessor_type>
```

24.7.3.6.3 Members

[`mdspan.mdspan.members`]

```
template<class... OtherIndexTypes>
constexpr reference operator[](OtherIndexTypes... indices) const;
```

Constraints:

- `(is_convertible_v<OtherIndexTypes, index_type> && ...)` is true,
- `(is_nothrow_constructible_v<index_type, OtherIndexTypes> && ...)` is true, and
- `sizeof...(OtherIndexTypes) == rank()` is true.

Let *I* be `extents_type::index-cast(std::move(indices))`.

Preconditions: *I* is a multidimensional index in `extents()`.

NOTE This implies that `map_(I) < map_.required_span_size()` is true.

Effects: Equivalent to:

```
return acc_.access(ptr_, map_(static_cast<index_type>(std::move(indices))...));
```

```
template<class OtherIndexType>
constexpr reference operator[](span<OtherIndexType, rank()> indices) const;
template<class OtherIndexType>
constexpr reference operator[](const array<OtherIndexType, rank()>& indices) const;
```

Constraints:

- `is_convertible_v<const OtherIndexType&, index_type>` is true, and
- `is_nothrow_constructible_v<index_type, const OtherIndexType&>` is true.

Effects: Let *P* be a parameter pack such that

```
is_same_v<make_index_sequence<rank()>, index_sequence<P...>>
```

is true. Equivalent to:

```
return operator[](as_const(indices[P])...);
```

```
constexpr size_type size() const noexcept;
```

Preconditions: The size of the multidimensional index space `extents()` is representable as a value of type `size_type` (6.8.2).

Returns: `extents().fwd-prod-of-extents(rank())`.

```
[[nodiscard]] constexpr bool empty() const noexcept;
```

Returns: true if the size of the multidimensional index space `extents()` is 0, otherwise false.

```
friend constexpr void swap(mdspan& x, mdspan& y) noexcept;
```

Effects: Equivalent to:

```
swap(x.ptr_, y.ptr_);
swap(x.map_, y.map_);
swap(x.acc_, y.acc_);
```

25

Iterators library

[iterators]

25.1

General

[iterators.general]

This Clause describes components that C++ programs may use to perform iterations over containers (Clause 24), streams (31.7), stream buffers (31.6), and other ranges (Clause 26).

The following subclauses describe iterator requirements, and components for iterator primitives, predefined iterators, and stream iterators, as summarized in Table 84.

Table 84 — Iterators library summary [tab:iterators.summary]

	Subclause	Header
25.3	Iterator requirements	<iterator>
25.4	Iterator primitives	
25.5	Iterator adaptors	
25.6	Stream iterators	
25.7	Range access	

25.2

template<class C> [[nodiscard]] constexpr auto
    empty(const C& c) -> decltype(c.empty()); // freestanding
template<class T, size_t N> [[nodiscard]] constexpr bool
    empty(const T (&array)[N]) noexcept; // freestanding
template<class E> [[nodiscard]] constexpr bool
    empty(initializer_list<E> il) noexcept; // freestanding
```

```

template<class C> constexpr auto data(C& c) -> decltype(c.data());           // freestanding
template<class C> constexpr auto data(const C& c) -> decltype(c.data());     // freestanding
template<class T, size_t N> constexpr T* data(T (&array)[N]) noexcept;      // freestanding
template<class E> constexpr const E* data(initializer_list<E> il) noexcept; // freestanding
}

```

25.3 Iterator requirements

[iterator.requirements]

25.3.1 General

[iterator.requirements.general]

Iterators are a generalization of pointers that allow a C++ program to work with different data structures (for example, containers and ranges) in a uniform manner. To be able to construct template algorithms that work correctly and efficiently on different types of data structures, the library formalizes not just the interfaces but also the semantics and complexity assumptions of iterators. An input iterator *i* supports the expression **i*, resulting in a value of some object type *T*, called the *value type* of the iterator. An output iterator *i* has a non-empty set of types that are **indirectly_writable** to the iterator; for each such type *T*, the expression **i = o* is valid where *o* is a value of type *T*. For every iterator type *X*, there is a corresponding signed integer-like type (25.3.4.4) called the *difference type* of the iterator.

Since iterators are an abstraction of pointers, their semantics are a generalization of most of the semantics of pointers in C++. This ensures that every function template that takes iterators works as well with regular pointers. This document defines six categories of iterators, according to the operations defined on them: *input iterators*, *output iterators*, *forward iterators*, *bidirectional iterators*, *random access iterators*, and *contiguous iterators*, as shown in Table 85.

Table 85 — Relations among iterator categories [tab:iterators.relations]

Contiguous	→	Random Access	→	Bidirectional	→	Forward	→	Input	→	Output

The six categories of iterators correspond to the iterator concepts

- `input_iterator` (25.3.4.9),
- `output_iterator` (25.3.4.10),
- `forward_iterator` (25.3.4.11),
- `bidirectional_iterator` (25.3.4.12),
- `random_access_iterator` (25.3.4.13), and
- `contiguous_iterator` (25.3.4.14),

respectively. The generic term *iterator* refers to any type that models the `input_or_output_iterator` concept (25.3.4.6).

Forward iterators meet all the requirements of input iterators and can be used whenever an input iterator is specified; Bidirectional iterators also meet all the requirements of forward iterators and can be used whenever a forward iterator is specified; Random access iterators also meet all the requirements of bidirectional iterators and can be used whenever a bidirectional iterator is specified; Contiguous iterators also meet all the requirements of random access iterators and can be used whenever a random access iterator is specified.

Iterators that further meet the requirements of output iterators are called *mutable iterators*. Nonmutable iterators are referred to as *constant iterators*.

In addition to the requirements in this subclause, the nested *typedef-names* specified in 25.3.2.3 shall be provided for the iterator type.

NOTE 1 Either the iterator type provides the *typedef-names* directly (in which case `iterator_traits` pick them up automatically), or an `iterator_traits` specialization provides them.

Just as a regular pointer to an array guarantees that there is a pointer value pointing past the last element of the array, so for any iterator type there is an iterator value that points past the last element of a corresponding sequence. Such a value is called a *past-the-end value*. Values of an iterator *i* for which the expression **i* is defined are called *dereferenceable*. The library never assumes that past-the-end values are dereferenceable. Iterators can also have singular values that are not associated with any sequence. Results of most expressions are undefined for singular values; the only exceptions are destroying an iterator that holds a singular value,

the assignment of a non-singular value to an iterator that holds a singular value, and, for iterators that meet the *Cpp17DefaultConstructible* requirements, using a value-initialized iterator as the source of a copy or move operation.

NOTE 2 This guarantee is not offered for default-initialization, although the distinction only matters for types with trivial default constructors such as pointers or aggregates holding pointers.

In these cases the singular value is overwritten the same way as any other value. Dereferenceable values are always non-singular.

Most of the library's algorithmic templates that operate on data structures have interfaces that use ranges. A *range* is an iterator and a *sentinel* that designate the beginning and end of the computation, or an iterator and a count that designate the beginning and the number of elements to which the computation is to be applied.²¹²

An iterator and a sentinel denoting a range are comparable. A range $[i, s)$ is empty if $i == s$; otherwise, $[i, s)$ refers to the elements in the data structure starting with the element pointed to by i and up to but not including the element, if any, pointed to by the first iterator j such that $j == s$.

A sentinel s is called *reachable from* an iterator i if and only if there is a finite sequence of applications of the expression $++i$ that makes $i == s$. If s is reachable from i , $[i, s)$ denotes a *valid range*.

A *counted range* $i + [0, n)$ is empty if $n == 0$; otherwise, $i + [0, n)$ refers to the n elements in the data structure starting with the element pointed to by i and up to but not including the element, if any, pointed to by the result of n applications of $++i$. A counted range $i + [0, n)$ is *valid* if and only if $n == 0$; or n is positive, i is dereferenceable, and $++i + [0, --n)$ is valid.

The result of the application of library functions to invalid ranges is undefined.

All the categories of iterators require only those functions that are realizable for a given category in constant time (amortized). Therefore, requirement tables and concept definitions for the iterators do not specify complexity.

Destruction of a non-forward iterator may invalidate pointers and references previously obtained from that iterator.

An *invalid iterator* is an iterator that may be singular.²¹³

Iterators are called *constexpr iterators* if all operations provided to meet iterator category requirements are constexpr functions.

NOTE 3 For example, the types “pointer to `int`” and `reverse_iterator<int*>` are constexpr iterators.

25.3.2 Associated types

[iterator.assoc.types]

25.3.2.1 Incrementable traits

[incrementable.traits]

To implement algorithms only in terms of incrementable types, it is often necessary to determine the difference type that corresponds to a particular incrementable type. Accordingly, it is required that if WI is the name of a type that models the `weakly_incrementable` concept (25.3.4.4), the type

```
iter_difference_t<WI>
```

be defined as the incrementable type's difference type.

```
namespace std {
    template<class> struct incrementable_traits { };

    template<class T>
        requires is_object_v<T>
        struct incrementable_traits<T*> {
            using difference_type = ptrdiff_t;
        };

    template<class I>
        struct incrementable_traits<const I>
            : incrementable_traits<I> { };
}
```

212) The sentinel denoting the end of a range can have the same type as the iterator denoting the beginning of the range, or a different type.

213) This definition applies to pointers, since pointers are iterators. The effect of dereferencing an iterator that has been invalidated is undefined.

```

template<class T>
    requires requires { typename T::difference_type; }
struct incrementable_traits<T> {
    using difference_type = typename T::difference_type;
};

template<class T>
    requires (!requires { typename T::difference_type; } &&
        requires(const T& a, const T& b) { { a - b } -> integral; })
struct incrementable_traits<T> {
    using difference_type = make_signed_t<decltype(declval<T>() - declval<T>())>;
};

template<class T>
    using iter_difference_t = see below;
}

```

Let R_I be `remove_cvref_t<I>`. The type `iter_difference_t<I>` denotes

- `incrementable_traits<R_I>::difference_type` if `iterator_traits<R_I>` names a specialization generated from the primary template, and
- `iterator_traits<R_I>::difference_type` otherwise.

Users may specialize `incrementable_traits` on program-defined types.

25.3.2.2 Indirectly readable traits

[readable.traits]

To implement algorithms only in terms of indirectly readable types, it is often necessary to determine the value type that corresponds to a particular indirectly readable type. Accordingly, it is required that if R is the name of a type that models the `indirectly_readable` concept (25.3.4.2), the type

`iter_value_t<R>`

be defined as the indirectly readable type's value type.

```

template<class> struct cond-value-type { }; // exposition only
template<class T>
    requires is_object_v<T>
struct cond-value-type<T> {
    using value_type = remove_cv_t<T>;
};

template<class T>
    concept has-member-value-type = requires { typename T::value_type; }; // exposition only

template<class T>
    concept has-member-element-type = requires { typename T::element_type; }; // exposition only

template<class> struct indirectly_readable_traits { };

template<class T>
struct indirectly_readable_traits<T*>
    : cond-value-type<T> { };

template<class I>
    requires is_array_v<I>
struct indirectly_readable_traits<I> {
    using value_type = remove_cv_t<remove_extent_t<I>>;
};

template<class I>
struct indirectly_readable_traits<const I>
    : indirectly_readable_traits<I> { };

template<has-member-value-type T>
struct indirectly_readable_traits<T>
    : cond-value-type<typename T::value_type> { };

```

```

template<has-member-element-type T>
struct indirectly_readable_traits<T>
    : cond-value-type<typename T::element_type> { };

template<has-member-value-type T>
    requires has-member-element-type<T>
struct indirectly_readable_traits<T> { };

template<has-member-value-type T>
    requires has-member-element-type<T> &&
        same_as<remove_cv_t<typename T::element_type>, remove_cv_t<typename T::value_type>>
struct indirectly_readable_traits<T>
    : cond-value-type<typename T::value_type> { };

template<class T> using iter_value_t = see below;

```

Let R_I be `remove_cvref_t<I>`. The type `iter_value_t<I>` denotes

- `indirectly_readable_traits<R_I>::value_type` if `iterator_traits<R_I>` names a specialization generated from the primary template, and
- `iterator_traits<R_I>::value_type` otherwise.

Class template `indirectly_readable_traits` may be specialized on program-defined types.

NOTE 1 Some legacy output iterators define a nested type named `value_type` that is an alias for `void`. These types are not `indirectly_readable` and have no associated value types.

NOTE 2 Smart pointers like `shared_ptr<int>` are `indirectly_readable` and have an associated value type, but a smart pointer like `shared_ptr<void>` is not `indirectly_readable` and has no associated value type.

25.3.2.3 Iterator traits

[iterator.traits]

To implement algorithms only in terms of iterators, it is sometimes necessary to determine the iterator category that corresponds to a particular iterator type. Accordingly, it is required that if `I` is the type of an iterator, the type

```
iterator_traits<I>::iterator_category
```

be defined as the iterator's iterator category. In addition, the types

```

iterator_traits<I>::pointer
iterator_traits<I>::reference

```

shall be defined as the iterator's pointer and reference types; that is, for an iterator object `a` of class type, the same type as `decltype(a.operator->())` and `decltype(*a)`, respectively. The type `iterator_traits<I>::pointer` shall be `void` for an iterator of class type `I` that does not support `operator->`. Additionally, in the case of an output iterator, the types

```

iterator_traits<I>::value_type
iterator_traits<I>::difference_type
iterator_traits<I>::reference

```

may be defined as `void`.

The definitions in this subclause make use of the following exposition-only concepts:

```

template<class I>
concept cpp17-iterator =
    requires(I i) {
        { *i } -> can-reference;
        { ++i } -> same_as<I&>;
        { *i++ } -> can-reference;
    } && copyable<I>;

template<class I>
concept cpp17-input-iterator =
    cpp17-iterator<I> && equality_comparable<I> && requires(I i) {
        typename incrementable_traits<I>::difference_type;
        typename indirectly_readable_traits<I>::value_type;
        typename common_reference_t<iter_reference_t<I>&&,
            typename indirectly_readable_traits<I>::value_type&>;
    }

```

```

    typename common_reference_t<decltype(*i++)&&,
                                typename indirectly_readable_traits<I>::value_type&>;
    requires signed_integral<typename incrementable_traits<I>::difference_type>;
};

template<class I>
concept cpp17-forward-iterator =
    cpp17-input-iterator<I> && constructible_from<I> &&
    is_reference_v<iter_reference_t<I>> &&
    same_as<remove_cvref_t<iter_reference_t<I>>,
            typename indirectly_readable_traits<I>::value_type> &&
    requires(I i) {
        { i++ } -> convertible_to<const I&>;
        { *i++ } -> same_as<iter_reference_t<I>>;
    };

template<class I>
concept cpp17-bidirectional-iterator =
    cpp17-forward-iterator<I> && requires(I i) {
        { --i } -> same_as<I&>;
        { i-- } -> convertible_to<const I&>;
        { *i-- } -> same_as<iter_reference_t<I>>;
    };

template<class I>
concept cpp17-random-access-iterator =
    cpp17-bidirectional-iterator<I> && totally_ordered<I> &&
    requires(I i, typename incrementable_traits<I>::difference_type n) {
        { i += n } -> same_as<I&>;
        { i -= n } -> same_as<I&>;
        { i + n } -> same_as<I>;
        { n + i } -> same_as<I>;
        { i - n } -> same_as<I>;
        { i - i } -> same_as<decltype(n)>;
        { i[n] } -> convertible_to<iter_reference_t<I>>;
    };

```

The members of a specialization `iterator_traits<I>` generated from the `iterator_traits` primary template are computed as follows:

- If `I` has valid (13.10.3) member types `difference_type`, `value_type`, `reference`, and `iterator_category`, then `iterator_traits<I>` has the following publicly accessible members:

```

using iterator_category = typename I::iterator_category;
using value_type        = typename I::value_type;
using difference_type    = typename I::difference_type;
using pointer           = see below;
using reference          = typename I::reference;

```

If the *qualified-id* `I::pointer` is valid and denotes a type, then `iterator_traits<I>::pointer` names that type; otherwise, it names `void`.

- Otherwise, if `I` satisfies the exposition-only concept `cpp17-input-iterator`, `iterator_traits<I>` has the following publicly accessible members:

```

using iterator_category = see below;
using value_type        = typename indirectly_readable_traits<I>::value_type;
using difference_type    = typename incrementable_traits<I>::difference_type;
using pointer           = see below;
using reference          = see below;

```

- If the *qualified-id* `I::pointer` is valid and denotes a type, `pointer` names that type. Otherwise, if `decltype(declval<I&>().operator->())` is well-formed, then `pointer` names that type. Otherwise, `pointer` names `void`.
- If the *qualified-id* `I::reference` is valid and denotes a type, `reference` names that type. Otherwise, `reference` names `iter_reference_t<I>`.

- If the *qualified-id* `I::iterator_category` is valid and denotes a type, `iterator_category` names that type. Otherwise, `iterator_category` names:
 - `random_access_iterator_tag` if `I` satisfies *cpp17-random-access-iterator*, or otherwise
 - `bidirectional_iterator_tag` if `I` satisfies *cpp17-bidirectional-iterator*, or otherwise
 - `forward_iterator_tag` if `I` satisfies *cpp17-forward-iterator*, or otherwise
 - `input_iterator_tag`.
- Otherwise, if `I` satisfies the exposition-only concept *cpp17-iterator*, then `iterator_traits<I>` has the following publicly accessible members:

```
using iterator_category = output_iterator_tag;
using value_type        = void;
using difference_type    = see below;
using pointer           = void;
using reference          = void;
```

If the *qualified-id* `incrementable_traits<I>::difference_type` is valid and denotes a type, then `difference_type` names that type; otherwise, it names `void`.

- Otherwise, `iterator_traits<I>` has no members by any of the above names.

Explicit or partial specializations of `iterator_traits` may have a member type `iterator_concept` that is used to indicate conformance to the iterator concepts (25.3.4).

EXAMPLE 1 To indicate conformance to the `input_iterator` concept but a lack of conformance to the *Cpp17InputIterator* requirements (25.3.5.3), an `iterator_traits` specialization can have `iterator_concept` denote `input_iterator_tag` and not define `iterator_category`.

`iterator_traits` is specialized for pointers as

```
namespace std {
  template<class T>
    requires is_object_v<T>
    struct iterator_traits<T*> {
      using iterator_concept = contiguous_iterator_tag;
      using iterator_category = random_access_iterator_tag;
      using value_type       = remove_cv_t<T>;
      using difference_type   = ptrdiff_t;
      using pointer          = T*;
      using reference         = T&;
    };
}
```

EXAMPLE 2 To implement a generic `reverse` function, a C++ program can do the following:

```
template<class BI>
void reverse(BI first, BI last) {
  typename iterator_traits<BI>::difference_type n =
    distance(first, last);
  --n;
  while(n > 0) {
    typename iterator_traits<BI>::value_type
      tmp = *first;
    *first++ = *--last;
    *last = tmp;
    n -= 2;
  }
}
```

25.3.3 Customization point objects

[iterator.cust]

25.3.3.1 `ranges::iter_move`

[iterator.cust.move]

The name `ranges::iter_move` denotes a customization point object (16.3.3.3.5). The expression `ranges::iter_move(E)` for a subexpression `E` is expression-equivalent to:

- `iter_move(E)`, if `E` has class or enumeration type and `iter_move(E)` is a well-formed expression when treated as an unevaluated operand, where the meaning of `iter_move` is established as-if by performing argument-dependent lookup only (6.5.4).

- Otherwise, if the expression `*E` is well-formed:
 - if `*E` is an lvalue, `std::move(*E)`;
 - otherwise, `*E`.
- Otherwise, `ranges::iter_move(E)` is ill-formed.

NOTE This case can result in substitution failure when `ranges::iter_move(E)` appears in the immediate context of a template instantiation.

If `ranges::iter_move(E)` is not equal to `*E`, the program is ill-formed, no diagnostic required.

25.3.3.2 `ranges::iter_swap`

[iterator.cust.swap]

The name `ranges::iter_swap` denotes a customization point object (16.3.3.3.5) that exchanges the values (18.4.9) denoted by its arguments.

Let *iter-exchange-move* be the exposition-only function:

```
template<class X, class Y>
constexpr iter_value_t<X> iter-exchange-move(X&& x, Y&& y)
noexcept(noexcept(iter_value_t<X>(iter_move(x))) &&
noexcept(*x = iter_move(y)));
```

Effects: Equivalent to:

```
iter_value_t<X> old_value(iter_move(x));
*x = iter_move(y);
return old_value;
```

The expression `ranges::iter_swap(E1, E2)` for subexpressions `E1` and `E2` is expression-equivalent to:

- `(void)iter_swap(E1, E2)`, if either `E1` or `E2` has class or enumeration type and `iter_swap(E1, E2)` is a well-formed expression with overload resolution performed in a context that includes the declaration

```
template<class I1, class I2>
void iter_swap(I1, I2) = delete;
```

and does not include a declaration of `ranges::iter_swap`. If the function selected by overload resolution does not exchange the values denoted by `E1` and `E2`, the program is ill-formed, no diagnostic required.

NOTE 1 This precludes calling unconstrained `std::iter_swap`. When the deleted overload is viable, program-defined overloads are only selected if they are more specialized (13.7.7.3).

- Otherwise, if the types of `E1` and `E2` each model `indirectly_readable`, and if the reference types of `E1` and `E2` model `swappable_with` (18.4.9), then `ranges::swap(*E1, *E2)`.
- Otherwise, if the types `T1` and `T2` of `E1` and `E2` model `indirectly_movable_storable<T1, T2>` and `indirectly_movable_storable<T2, T1>`, then `(void)(*E1 = iter-exchange-move(E2, E1))`, except that `E1` is evaluated only once.
- Otherwise, `ranges::iter_swap(E1, E2)` is ill-formed.

NOTE 2 This case can result in substitution failure when `ranges::iter_swap(E1, E2)` appears in the immediate context of a template instantiation.

25.3.4 Iterator concepts

[iterator.concepts]

25.3.4.1 General

[iterator.concepts.general]

For a type `I`, let `ITER_TRAITS(I)` denote the type `I` if `iterator_traits<I>` names a specialization generated from the primary template. Otherwise, `ITER_TRAITS(I)` denotes `iterator_traits<I>`.

- If the *qualified-id* `ITER_TRAITS(I)::iterator_concept` is valid and names a type, then `ITER_CONCEPT(I)` denotes that type.
- Otherwise, if the *qualified-id* `ITER_TRAITS(I)::iterator_category` is valid and names a type, then `ITER_CONCEPT(I)` denotes that type.
- Otherwise, if `iterator_traits<I>` names a specialization generated from the primary template, then `ITER_CONCEPT(I)` denotes `random_access_iterator_tag`.
- Otherwise, `ITER_CONCEPT(I)` does not denote a type.

NOTE `ITER_TRAITS` enables independent syntactic determination of an iterator's category and concept.

EXAMPLE

```

struct I {
    using value_type = int;
    using difference_type = int;

    int operator*() const;
    I& operator++();
    I operator++(int);
    I& operator--();
    I operator--(int);

    bool operator==(I) const;
};

```

`iterator_traits<I>::iterator_category` denotes `input_iterator_tag`, and `ITER_CONCEPT(I)` denotes `random_access_iterator_tag`.

25.3.4.2 Concept `indirectly_readable`

[iterator.concept.readable]

Types that are indirectly readable by applying `operator*` model the `indirectly_readable` concept, including pointers, smart pointers, and iterators.

```

template<class In>
concept indirectly_readable_impl =
    requires(const In in) {
        typename iter_value_t<In>;
        typename iter_reference_t<In>;
        typename iter_rvalue_reference_t<In>;
        { *in } -> same_as<iter_reference_t<In>>;
        { ranges::iter_move(in) } -> same_as<iter_rvalue_reference_t<In>>;
    } &&
    common_reference_with<iter_reference_t<In>&&, iter_value_t<In>&& &&
    common_reference_with<iter_reference_t<In>&&, iter_rvalue_reference_t<In>&& &&
    common_reference_with<iter_rvalue_reference_t<In>&&, const iter_value_t<In>&& >;

template<class In>
concept indirectly_readable =
    indirectly_readable_impl<remove_cvref_t<In>>;

```

Given a value `i` of type `I`, `I` models `indirectly_readable` only if the expression `*i` is equality-preserving.

25.3.4.3 Concept `indirectly_writable`

[iterator.concept.writable]

The `indirectly_writable` concept specifies the requirements for writing a value into an iterator's referenced object.

```

template<class Out, class T>
concept indirectly_writable =
    requires(Out&& o, T&& t) {
        *o = std::forward<T>(t); // not required to be equality-preserving
        *std::forward<Out>(o) = std::forward<T>(t); // not required to be equality-preserving
        const_cast<const iter_reference_t<Out>&&(>(*o) =
            std::forward<T>(t); // not required to be equality-preserving
        const_cast<const iter_reference_t<Out>&&(>(*std::forward<Out>(o)) =
            std::forward<T>(t); // not required to be equality-preserving
    };

```

Let `E` be an expression such that `decltype(E)` is `T`, and let `o` be a dereferenceable object of type `Out`. `Out` and `T` model `indirectly_writable<Out, T>` only if:

- If `Out` and `T` model `indirectly_readable<Out> && same_as<iter_value_t<Out>, decay_t<T>>`, then `*o` after any above assignment is equal to the value of `E` before the assignment.

After evaluating any above assignment expression, `o` is not required to be dereferenceable.

If `E` is an xvalue (7.2.1), the resulting state of the object it denotes is valid but unspecified (16.4.6.15).

NOTE 1 The only valid use of an `operator*` is on the left side of the assignment statement. Assignment through the same value of the indirectly writable type happens only once.

NOTE 2 `indirectly_writable` has the awkward `const_cast` expressions to reject iterators with prvalue non-proxy reference types that permit rvalue assignment but do not also permit `const` rvalue assignment. Consequently, an iterator type `I` that returns `std::string` by value does not model `indirectly_writable<I, std::string>`.

25.3.4.4 Concept `weakly_incrementable`

[`iterator.concept.winc`]

The `weakly_incrementable` concept specifies the requirements on types that can be incremented with the pre- and post-increment operators. The increment operations are not required to be equality-preserving, nor is the type required to be `equality_comparable`.

```
template<class T>
    constexpr bool is-integer-like = see below;           // exposition only

template<class T>
    constexpr bool is-signed-integer-like = see below;     // exposition only

template<class I>
    concept weakly_incrementable =
        movable<I> &&
        requires(I i) {
            typename iter_difference_t<I>;
            requires is-signed-integer-like<iter_difference_t<I>>;
            { ++i } -> same_as<I&>;    // not required to be equality-preserving
            i++;                       // not required to be equality-preserving
        };
```

A type `I` is an *integer-class type* if it is in a set of implementation-defined types that behave as integer types do, as defined below.

NOTE 1 An integer-class type is not necessarily a class type.

The range of representable values of an integer-class type is the continuous set of values over which it is defined. For any integer-class type, its range of representable values is either -2^{N-1} to $2^{N-1} - 1$ (inclusive) for some integer N , in which case it is a *signed-integer-class type*, or 0 to $2^N - 1$ (inclusive) for some integer N , in which case it is an *unsigned-integer-class type*. In both cases, N is called the *width* of the integer-class type. The width of an integer-class type is greater than that of every integral type of the same signedness.

A type `I` other than `cv bool` is *integer-like* if it models `integral<I>` or if it is an integer-class type. An integer-like type `I` is *signed-integer-like* if it models `signed_integral<I>` or if it is a signed-integer-class type. An integer-like type `I` is *unsigned-integer-like* if it models `unsigned_integral<I>` or if it is an unsigned-integer-class type.

For every integer-class type `I`, let `B(I)` be a unique hypothetical extended integer type of the same signedness with the same width (6.8.2) as `I`.

NOTE 2 The corresponding hypothetical specialization `numeric_limits<B(I)>` meets the requirements on `numeric_limits` specializations for integral types (17.3.5).

For every integral type `J`, let `B(J)` be the same type as `J`.

Expressions of integer-class type are explicitly convertible to any integer-like type, and implicitly convertible to any integer-class type of equal or greater width and the same signedness. Expressions of integral type are both implicitly and explicitly convertible to any integer-class type. Conversions between integral and integer-class types and between two integer-class types do not exit via an exception. The result of such a conversion is the unique value of the destination type that is congruent to the source modulo 2^N , where N is the width of the destination type.

Let `a` be an object of integer-class type `I`, let `b` be an object of integer-like type `I2` such that the expression `b` is implicitly convertible to `I`, let `x` and `y` be, respectively, objects of type `B(I)` and `B(I2)` as described above that represent the same values as `a` and `b`, and let `c` be an lvalue of any integral type.

- The expressions `a++` and `a--` shall be prvalues of type `I` whose values are equal to that of `a` prior to the evaluation of the expressions. The expression `a++` shall modify the value of `a` by adding 1 to it. The expression `a--` shall modify the value of `a` by subtracting 1 from it.
- The expressions `++a`, `--a`, and `&a` shall be expression-equivalent to `a += 1`, `a -= 1`, and `addressof(a)`, respectively.

- For every *unary-operator* @ other than & for which the expression @x is well-formed, @a shall also be well-formed and have the same value, effects, and value category as @x. If @x has type bool, so too does @a; if @x has type B(I), then @a has type I.
- For every assignment operator @= for which c @= x is well-formed, c @= a shall also be well-formed and shall have the same value and effects as c @= x. The expression c @= a shall be an lvalue referring to c.
- For every assignment operator @= for which x @= y is well-formed, a @= b shall also be well-formed and shall have the same effects as x @= y, except that the value that would be stored into x is stored into a. The expression a @= b shall be an lvalue referring to a.
- For every non-assignment binary operator @ for which x @ y and y @ x are well-formed, a @ b and b @ a shall also be well-formed and shall have the same value, effects, and value category as x @ y and y @ x, respectively. If x @ y or y @ x has type B(I), then a @ b or b @ a, respectively, has type I; if x @ y or y @ x has type B(I2), then a @ b or b @ a, respectively, has type I2; if x @ y or y @ x has any other type, then a @ b or b @ a, respectively, has that type.

An expression E of integer-class type I is contextually convertible to bool as if by `bool(E != I(0))`.

All integer-class types model **regular** (18.6) and **three_way_comparable<strong_ordering>** (17.11.4).

A value-initialized object of integer-class type has value 0.

For every (possibly cv-qualified) integer-class type I, `numeric_limits<I>` is specialized such that each static data member m has the same value as `numeric_limits<B(I)>::m`, and each static member function f returns `I(numeric_limits<B(I)>::f())`.

For any two integer-like types I1 and I2, at least one of which is an integer-class type, `common_type_t<I1, I2>` denotes an integer-class type whose width is not less than that of I1 or I2. If both I1 and I2 are signed-integer-like types, then `common_type_t<I1, I2>` is also a signed-integer-like type.

is-integer-like<I> is true if and only if I is an integer-like type. *is-signed-integer-like*<I> is true if and only if I is a signed-integer-like type.

Let i be an object of type I. When i is in the domain of both pre- and post-increment, i is said to be *incrementable*. I models **weakly_incrementable**<I> only if:

- The expressions ++i and i++ have the same domain.
- If i is incrementable, then both ++i and i++ advance i to the next element.
- If i is incrementable, then `addressof(++i)` is equal to `addressof(i)`.

Recommended practice: The implementation of an algorithm on a weakly incrementable type should never attempt to pass through the same incrementable value twice; such an algorithm should be a single-pass algorithm.

NOTE 3 For **weakly_incrementable** types, a equals b does not imply that ++a equals ++b. (Equality does not guarantee the substitution property or referential transparency.) Such algorithms can be used with `istream` as the source of the input data through the `istream_iterator` class template.

25.3.4.5 Concept **incrementable**

[iterator.concept.inc]

The **incrementable** concept specifies requirements on types that can be incremented with the pre- and post-increment operators. The increment operations are required to be equality-preserving, and the type is required to be **equality_comparable**.

NOTE 1 This supersedes the annotations on the increment expressions in the definition of **weakly_incrementable**.

```
template<class I>
concept incrementable =
    regular<I> &&
    weakly_incrementable<I> &&
    requires(I i) {
        { i++ } -> same_as<I>;
    };

```

Let a and b be incrementable objects of type I. I models **incrementable** only if:

- If `bool(a == b)` then `bool(a++ == b)`.
- If `bool(a == b)` then `bool(((void)a++, a) == ++b)`.

NOTE 2 The requirement that **a** equals **b** implies **++a** equals **++b** (which is not true for weakly incrementable types) allows the use of multi-pass one-directional algorithms with types that model **incrementable**.

25.3.4.6 Concept `input_or_output_iterator`

[`iterator.concept.iterator`]

The `input_or_output_iterator` concept forms the basis of the iterator concept taxonomy; every iterator models `input_or_output_iterator`. This concept specifies operations for dereferencing and incrementing an iterator. Most algorithms will require additional operations to compare iterators with sentinels (25.3.4.7), to read (25.3.4.9) or write (25.3.4.10) values, or to provide a richer set of iterator movements (25.3.4.11, 25.3.4.12, 25.3.4.13).

```
template<class I>
concept input_or_output_iterator =
    requires(I i) {
        { *i } -> can-reference;
    } &&
    weakly_incrementable<I>;
```

NOTE Unlike the *Cpp17Iterator* requirements, the `input_or_output_iterator` concept does not require copyability.

25.3.4.7 Concept `sentinel_for`

[`iterator.concept.sentinel`]

The `sentinel_for` concept specifies the relationship between an `input_or_output_iterator` type and a semiregular type whose values denote a range.

```
template<class S, class I>
concept sentinel_for =
    semiregular<S> &&
    input_or_output_iterator<I> &&
    weakly_equality_comparable_with<S, I>; // see 18.5.4
```

Let **s** and **i** be values of type **S** and **I** such that **[i, s)** denotes a range. Types **S** and **I** model `sentinel_for<S, I>` only if:

- **i == s** is well-defined.
- If **bool(i != s)** then **i** is dereferenceable and **[++i, s)** denotes a range.
- `assignable_from<I&, S>` is either modeled or not satisfied.

The domain of **==** is not static. Given an iterator **i** and sentinel **s** such that **[i, s)** denotes a range and **i != s**, **i** and **s** are not required to continue to denote a range after incrementing any other iterator equal to **i**. Consequently, **i == s** is no longer required to be well-defined.

25.3.4.8 Concept `sized_sentinel_for`

[`iterator.concept.sizedsentinel`]

The `sized_sentinel_for` concept specifies requirements on an `input_or_output_iterator` type **I** and a corresponding `sentinel_for<I>` that allow the use of the **-** operator to compute the distance between them in constant time.

```
template<class S, class I>
concept sized_sentinel_for =
    sentinel_for<S, I> &&
    !disable_sized_sentinel_for<remove_cv_t<S>, remove_cv_t<I>> &&
    requires(const I& i, const S& s) {
        { s - i } -> same_as<iter_difference_t<I>>;
        { i - s } -> same_as<iter_difference_t<I>>;
    };
```

Let **i** be an iterator of type **I**, and **s** a sentinel of type **S** such that **[i, s)** denotes a range. Let **N** be the smallest number of applications of **++i** necessary to make **bool(i == s)** be true. **S** and **I** model `sized_sentinel_for<S, I>` only if:

- If **N** is representable by `iter_difference_t<I>`, then **s - i** is well-defined and equals **N**.
- If **-N** is representable by `iter_difference_t<I>`, then **i - s** is well-defined and equals **-N**.

```
template<class S, class I>
constexpr bool disable_sized_sentinel_for = false;
```

Remarks: Pursuant to 16.4.5.2.1, users may specialize `disable_sized_sentinel_for` for cv-unqualified non-array object types `S` and `I` if `S` and/or `I` is a program-defined type. Such specializations shall be usable in constant expressions (7.7) and have type `const bool`.

NOTE `disable_sized_sentinel_for` allows use of sentinels and iterators with the library that satisfy but do not in fact model `sized_sentinel_for`.

EXAMPLE The `sized_sentinel_for` concept is modeled by pairs of `random_access_iterators` (25.3.4.13) and by counted iterators and their sentinels (25.5.7.1).

25.3.4.9 Concept `input_iterator`

[iterator.concept.input]

The `input_iterator` concept defines requirements for a type whose referenced values can be read (from the requirement for `indirectly_readable` (25.3.4.2)) and which can be both pre- and post-incremented.

NOTE Unlike the *Cpp17InputIterator* requirements (25.3.5.3), the `input_iterator` concept does not need equality comparison since iterators are typically compared to sentinels.

```
template<class I>
concept input_iterator =
    input_or_output_iterator<I> &&
    indirectly_readable<I> &&
    requires { typename ITER_CONCEPT(I); } &&
    derived_from<ITER_CONCEPT(I), input_iterator_tag>;
```

25.3.4.10 Concept `output_iterator`

[iterator.concept.output]

The `output_iterator` concept defines requirements for a type that can be used to write values (from the requirement for `indirectly_writable` (25.3.4.3)) and which can be both pre- and post-incremented.

NOTE Output iterators are not required to model `equality_comparable`.

```
template<class I, class T>
concept output_iterator =
    input_or_output_iterator<I> &&
    indirectly_writable<I, T> &&
    requires(I i, T&& t) {
        *i++ = std::forward<T>(t); // not required to be equality-preserving
    };
```

Let `E` be an expression such that `decltype((E))` is `T`, and let `i` be a dereferenceable object of type `I`. `I` and `T` model `output_iterator<I, T>` only if `*i++ = E`; has effects equivalent to:

```
*i = E;
++i;
```

Recommended practice: The implementation of an algorithm on output iterators should never attempt to pass through the same iterator twice; such an algorithm should be a single-pass algorithm.

25.3.4.11 Concept `forward_iterator`

[iterator.concept.forward]

The `forward_iterator` concept adds copyability, equality comparison, and the multi-pass guarantee, specified below.

```
template<class I>
concept forward_iterator =
    input_iterator<I> &&
    derived_from<ITER_CONCEPT(I), forward_iterator_tag> &&
    incrementable<I> &&
    sentinel_for<I, I>;
```

The domain of `==` for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators of the same type may be compared and shall compare equal to other value-initialized iterators of the same type.

NOTE 1 Value-initialized iterators behave as if they refer past the end of the same empty sequence.

Pointers and references obtained from a forward iterator into a range `[i, s)` shall remain valid while `[i, s)` continues to denote a range.

Two dereferenceable iterators `a` and `b` of type `X` offer the *multi-pass guarantee* if

- `a == b` implies `++a == ++b` and
- the expression `((void)[] (X x){++x;}(a), *a)` is equivalent to the expression `*a`.

NOTE 2 The requirement that `a == b` implies `++a == ++b` and the removal of the restrictions on the number of assignments through a mutable iterator (which applies to output iterators) allow the use of multi-pass one-directional algorithms with forward iterators.

25.3.4.12 Concept `bidirectional_iterator`

[`iterator.concept.bidir`]

The `bidirectional_iterator` concept adds the ability to move an iterator backward as well as forward.

```
template<class I>
concept bidirectional_iterator =
    forward_iterator<I> &&
    derived_from<ITER_CONCEPT(I), bidirectional_iterator_tag> &&
    requires(I i) {
        { --i } -> same_as<I&&>;
        { i-- } -> same_as<I>;
    };

```

A bidirectional iterator `r` is decrementable if and only if there exists some `q` such that `++q == r`. Decrementable iterators `r` shall be in the domain of the expressions `--r` and `r--`.

Let `a` and `b` be equal objects of type `I`. `I` models `bidirectional_iterator` only if

- If `a` and `b` are decrementable, then all of the following are true:
 - `addressof(--a) == addressof(a)`
 - `bool(a-- == b)`
 - after evaluating both `a--` and `--b`, `bool(a == b)` is still true
 - `bool(++(--a) == b)`
- If `a` and `b` are incrementable, then `bool(--(++a) == b)`.

25.3.4.13 Concept `random_access_iterator`

[`iterator.concept.random.access`]

The `random_access_iterator` concept adds support for constant-time advancement with `+=`, `+`, `-=`, and `-`, as well as the computation of distance in constant time with `-`. Random access iterators also support array notation via subscripting.

```
template<class I>
concept random_access_iterator =
    bidirectional_iterator<I> &&
    derived_from<ITER_CONCEPT(I), random_access_iterator_tag> &&
    totally_ordered<I> &&
    sized_sentinel_for<I, I> &&
    requires(I i, const I j, const iter_difference_t<I> n) {
        { i += n } -> same_as<I&&>;
        { j + n } -> same_as<I>;
        { n + j } -> same_as<I>;
        { i -= n } -> same_as<I&&>;
        { j - n } -> same_as<I>;
        { j[n] } -> same_as<iter_reference_t<I>>;
    };

```

Let `a` and `b` be valid iterators of type `I` such that `b` is reachable from `a` after `n` applications of `++a`, let `D` be `iter_difference_t<I>`, and let `n` denote a value of type `D`. `I` models `random_access_iterator` only if:

- `(a += n)` is equal to `b`.
- `addressof(a += n)` is equal to `addressof(a)`.
- `(a + n)` is equal to `(a += n)`.
- For any two positive values `x` and `y` of type `D`, if `(a + D(x + y))` is valid, then `(a + D(x + y))` is equal to `((a + x) + y)`.
- `(a + D(0))` is equal to `a`.
- If `(a + D(n - 1))` is valid, then `(a + n)` is equal to `[] (I c){ return ++c; }(a + D(n - 1))`.

- $(b \neq D(-n))$ is equal to a .
- $(b \neq n)$ is equal to a .
- $\text{addressof}(b \neq n)$ is equal to $\text{addressof}(b)$.
- $(b - n)$ is equal to $(b \neq n)$.
- If b is dereferenceable, then $a[n]$ is valid and is equal to $*b$.
- $\text{bool}(a \leq b)$ is true.

25.3.4.14 Concept `contiguous_iterator`

[iterator.concept.contiguous]

The `contiguous_iterator` concept provides a guarantee that the denoted elements are stored contiguously in memory.

```
template<class I>
concept contiguous_iterator =
    random_access_iterator<I> &&
    derived_from<ITER_CONCEPT(I), contiguous_iterator_tag> &&
    is_lvalue_reference_v<iter_reference_t<I>> &&
    same_as<iter_value_t<I>, remove_cvref_t<iter_reference_t<I>>> &&
    requires(const I& i) {
        { to_address(i) } -> same_as<add_pointer_t<iter_reference_t<I>>>;
    };

```

Let a and b be dereferenceable iterators and c be a non-dereferenceable iterator of type I such that b is reachable from a and c is reachable from b , and let D be `iter_difference_t<I>`. The type I models `contiguous_iterator` only if

- $\text{to\_address}(a) == \text{addressof}(*a)$,
- $\text{to\_address}(b) == \text{to\_address}(a) + D(b - a)$,
- $\text{to\_address}(c) == \text{to\_address}(a) + D(c - a)$,
- $\text{ranges::iter\_move}(a)$ has the same type, value category, and effects as $\text{std::move}(*a)$, and
- if $\text{ranges::iter\_swap}(a, b)$ is well-formed, it has effects equivalent to $\text{ranges::swap}(*a, *b)$.

25.3.5 C++17 iterator requirements

[iterator.cpp17]

25.3.5.1 General

[iterator.cpp17.general]

In the following sections, a and b denote values of type X or `const X`, `difference_type` and `reference` refer to the types `iterator_traits<X>::difference_type` and `iterator_traits<X>::reference`, respectively, n denotes a value of `difference_type`, u , tmp , and m denote identifiers, r denotes a value of $X\&$, t denotes a value of value type T , o denotes a value of some type that is writable to the output iterator.

NOTE The program is ill-formed if, for an iterator type X , the specialization `iterator_traits<X>` (25.3.2.3) is ill-formed.

25.3.5.2 *Cpp17Iterator*

[iterator.iterators]

The *Cpp17Iterator* requirements form the basis of the iterator taxonomy; every iterator meets the *Cpp17Iterator* requirements. This set of requirements specifies operations for dereferencing and incrementing an iterator. Most algorithms will require additional operations to read (25.3.5.3) or write (25.3.5.4) values, or to provide a richer set of iterator movements (25.3.5.5, 25.3.5.6, 25.3.5.7).

A type X meets the *Cpp17Iterator* requirements if

- X meets the *Cpp17CopyConstructible*, *Cpp17CopyAssignable*, *Cpp17Swappable*, and *Cpp17Destructible* requirements (16.4.4.2, 16.4.4.3), and
- `iterator_traits<X>::difference_type` is a signed integer type or `void`, and
- the expressions in Table 86 are valid and have the indicated semantics.

25.3.5.3 Input iterators

[input.iterators]

A class or pointer type X meets the requirements of an input iterator for the value type T if X meets the *Cpp17Iterator* (25.3.5.2) and *Cpp17EqualityComparable* (Table 28) requirements and the expressions in Table 87 are valid and have the indicated semantics.

Table 86 — *Cpp17Iterator* requirements [tab:iterator]

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
<code>*r</code>	unspecified		<i>Preconditions:</i> <code>r</code> is dereferenceable.
<code>++r</code>	<code>X&</code>		

In Table 87, the term *the domain of ==* is used in the ordinary mathematical sense to denote the set of values over which `==` is (required to be) defined. This set can change over time. Each algorithm places additional requirements on the domain of `==` for the iterator values it uses. These requirements can be inferred from the uses that algorithm makes of `==` and `!=`.

EXAMPLE The call `find(a,b,x)` is defined only if the value of `a` has the property *p* defined as follows: `b` has property *p* and a value `i` has property *p* if `(*i==x)` or if `(*i!=x` and `++i` has property *p*).

Table 87 — *Cpp17InputIterator* requirements (in addition to *Cpp17Iterator*) [tab:inputiterator]

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
<code>a != b</code>	<code>decltype(a != b)</code> models <i>boolean-testable</i>	<code>!(a == b)</code>	<i>Preconditions:</i> <code>(a, b)</code> is in the domain of <code>==</code> .
<code>*a</code>	reference, convertible to <code>T</code>		<i>Preconditions:</i> <code>a</code> is dereferenceable. The expression <code>(void)*a</code> , <code>*a</code> is equivalent to <code>*a</code> . If <code>a == b</code> and <code>(a, b)</code> is in the domain of <code>==</code> then <code>*a</code> is equivalent to <code>*b</code> .
<code>a->m</code>		<code>(*a).m</code>	<i>Preconditions:</i> <code>a</code> is dereferenceable.
<code>++r</code>	<code>X&</code>		<i>Preconditions:</i> <code>r</code> is dereferenceable. <i>Postconditions:</i> <code>r</code> is dereferenceable or <code>r</code> is past-the-end; any copies of the previous value of <code>r</code> are no longer required to be dereferenceable nor to be in the domain of <code>==</code> .
<code>(void)r++</code>			equivalent to <code>(void)++r</code>
<code>*r++</code>	convertible to <code>T</code>	<pre>{ T tmp = *r; ++r; return tmp; }</pre>	

Recommended practice: The implementation of an algorithm on input iterators should never attempt to pass through the same iterator twice; such an algorithm should be a single pass algorithm.

NOTE For input iterators, $a == b$ does not imply $++a == ++b$. (Equality does not guarantee the substitution property or referential transparency.) Value type T is not required to be a *Cpp17CopyAssignable* type (Table 34). Such an algorithm can be used with istreams as the source of the input data through the *istream_iterator* class template.

25.3.5.4 Output iterators

[output.iterators]

A class or pointer type X meets the requirements of an output iterator if X meets the *Cpp17Iterator* requirements (25.3.5.2) and the expressions in Table 88 are valid and have the indicated semantics.

Table 88 — *Cpp17OutputIterator* requirements (in addition to *Cpp17Iterator*)
[tab:outputiterator]

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
$*r = o$	result is not used		<i>Remarks:</i> After this operation r is not required to be dereferenceable. <i>Postconditions:</i> r is incrementable.
$++r$	$X\&$		$\text{addressof}(r) == \text{addressof}(++r)$. <i>Remarks:</i> After this operation r is not required to be dereferenceable. <i>Postconditions:</i> r is incrementable.
$r++$	convertible to $\text{const } X\&$	$\{ X \text{ tmp} = r;$ $++r;$ $\text{return tmp}; \}$	<i>Remarks:</i> After this operation r is not required to be dereferenceable. <i>Postconditions:</i> r is incrementable.
$*r++ = o$	result is not used		<i>Remarks:</i> After this operation r is not required to be dereferenceable. <i>Postconditions:</i> r is incrementable.

Recommended practice: The implementation of an algorithm on output iterators should never attempt to pass through the same iterator twice; such an algorithm should be a single-pass algorithm.

NOTE The only valid use of an **operator*** is on the left side of the assignment statement. Assignment through the same value of the iterator happens only once. Equality and inequality are not necessarily defined.

25.3.5.5 Forward iterators

[forward.iterators]

A class or pointer type X meets the requirements of a forward iterator if

- X meets the *Cpp17InputIterator* requirements (25.3.5.3),
- X meets the *Cpp17DefaultConstructible* requirements (16.4.4.2),
- if X is a mutable iterator, **reference** is a reference to T ; if X is a constant iterator, **reference** is a reference to $\text{const } T$,
- the expressions in Table 89 are valid and have the indicated semantics, and
- objects of type X offer the multi-pass guarantee, described below.

The domain of $==$ for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators may be compared and shall compare equal to other value-initialized iterators of the same type.

NOTE 1 Value-initialized iterators behave as if they refer past the end of the same empty sequence.

Two dereferenceable iterators **a** and **b** of type **X** offer the *multi-pass guarantee* if

- **a** == **b** implies ++**a** == ++**b** and
- **X** is a pointer type or the expression (void)++**X**(**a**), ***a** is equivalent to the expression ***a**.

NOTE 2 The requirement that **a** == **b** implies ++**a** == ++**b** (which is not true for input and output iterators) and the removal of the restrictions on the number of the assignments through a mutable iterator (which applies to output iterators) allows the use of multi-pass one-directional algorithms with forward iterators.

Table 89 — Cpp17ForwardIterator requirements (in addition to Cpp17InputIterator)
[tab:forwarditerator]

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
r ++	convertible to const X &	{ X tmp = r ; ++ r ; return tmp; }	
* r ++	reference		

If **a** and **b** are equal, then either **a** and **b** are both dereferenceable or else neither is dereferenceable.

If **a** and **b** are both dereferenceable, then **a** == **b** if and only if ***a** and ***b** are bound to the same object.

25.3.5.6 Bidirectional iterators

[bidirectional.iterators]

A class or pointer type **X** meets the requirements of a bidirectional iterator if, in addition to meeting the Cpp17ForwardIterator requirements, the following expressions are valid as shown in Table 90.

Table 90 — Cpp17BidirectionalIterator requirements (in addition to Cpp17ForwardIterator)
[tab:bidirectionaliterator]

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
-- r	X &		<i>Preconditions:</i> there exists s such that r == ++ s . <i>Postconditions:</i> r is dereferenceable. --(++ r) == r . -- r == -- s implies r == s . addressof(r) == addressof(-- r).
r --	convertible to const X &	{ X tmp = r ; -- r ; return tmp; }	
* r --	reference		

NOTE Bidirectional iterators allow algorithms to move iterators backward as well as forward.

25.3.5.7 Random access iterators

[random.access.iterators]

A class or pointer type **X** meets the requirements of a random access iterator if, in addition to meeting the Cpp17BidirectionalIterator requirements, the following expressions are valid as shown in Table 91.

Table 91 — *Cpp17RandomAccessIterator* requirements (in addition to *Cpp17BidirectionalIterator*) [tab:randomaccessiterator]

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
<code>r += n</code>	<code>X&</code>	{ <code>difference_type m = n;</code> if (<code>m >= 0</code>) while (<code>m--</code>) ++ <code>r</code> ; else while (<code>m++</code>) -- <code>r</code> ; return <code>r</code> ; }	
<code>a + n</code> <code>n + a</code>	<code>X</code>	{ <code>X tmp = a;</code> return <code>tmp += n</code> ; }	<code>a + n == n + a</code> .
<code>r -= n</code>	<code>X&</code>	return <code>r += -n</code> ;	<i>Preconditions:</i> the absolute value of <code>n</code> is in the range of representable values of <code>difference_type</code> .
<code>a - n</code>	<code>X</code>	{ <code>X tmp = a;</code> return <code>tmp -= n</code> ; }	
<code>b - a</code>	<code>difference_type</code>	return <code>n</code> ;	<i>Preconditions:</i> there exists a value <code>n</code> of type <code>difference_type</code> such that <code>a + n == b</code> . <code>b == a + (b - a)</code> .
<code>a[n]</code>	convertible to reference	<code>*(a + n)</code>	
<code>a < b</code>	<code>decltype(a < b)</code> models <i>boolean-testable</i>	<i>Effects:</i> Equivalent to: return <code>b - a > 0</code> ;	<code><</code> is a total ordering relation
<code>a > b</code>	<code>decltype(a > b)</code> models <i>boolean-testable</i>	<code>b < a</code>	<code>></code> is a total ordering relation opposite to <code><</code> .
<code>a >= b</code>	<code>decltype(a >= b)</code> models <i>boolean-testable</i>	<code>!(a < b)</code>	
<code>a <= b</code>	<code>decltype(a <= b)</code> models <i>boolean-testable</i>	<code>!(a > b)</code>	

25.3.6 Indirect callable requirements

[indirectcallable]

25.3.6.1 General

[indirectcallable.general]

There are several concepts that group requirements of algorithms that take callable objects (22.10.3) as arguments.

25.3.6.2 Indirect callable traits

[indirectcallable.traits]

To implement algorithms taking projections, it is necessary to determine the projected type of an iterator's value type. For the exposition-only alias template *indirect-value-t*, *indirect-value-t*<*T*> denotes

- `invoke_result_t<Proj&, indirect-value-t<I>>` if *T* names `projected<I, Proj>`, and
- `iter_value_t<T>&` otherwise.

25.3.6.3 Indirect callables

[indirectcallable.indirectinvocable]

The indirect callable concepts are used to constrain those algorithms that accept callable objects (22.10.3) as arguments.

```

namespace std {
    template<class F, class I>
    concept indirectly_unary_invocable =
        indirectly_readable<I> &&
        copy_constructible<F> &&
        invocable<F&, indirect_value_t<I>> &&
        invocable<F&, iter_reference_t<I>> &&
        invocable<F&, iter_common_reference_t<I>> &&
        common_reference_with<
            invoke_result_t<F&, indirect_value_t<I>>,
            invoke_result_t<F&, iter_reference_t<I>>>;

    template<class F, class I>
    concept indirectly_regular_unary_invocable =
        indirectly_readable<I> &&
        copy_constructible<F> &&
        regular_invocable<F&, indirect_value_t<I>> &&
        regular_invocable<F&, iter_reference_t<I>> &&
        regular_invocable<F&, iter_common_reference_t<I>> &&
        common_reference_with<
            invoke_result_t<F&, indirect_value_t<I>>,
            invoke_result_t<F&, iter_reference_t<I>>>;

    template<class F, class I>
    concept indirect_unary_predicate =
        indirectly_readable<I> &&
        copy_constructible<F> &&
        predicate<F&, indirect_value_t<I>> &&
        predicate<F&, iter_reference_t<I>> &&
        predicate<F&, iter_common_reference_t<I>>;

    template<class F, class I1, class I2>
    concept indirect_binary_predicate =
        indirectly_readable<I1> && indirectly_readable<I2> &&
        copy_constructible<F> &&
        predicate<F&, indirect_value_t<I1>, indirect_value_t<I2>> &&
        predicate<F&, indirect_value_t<I1>, iter_reference_t<I2>> &&
        predicate<F&, iter_reference_t<I1>, indirect_value_t<I2>> &&
        predicate<F&, iter_reference_t<I1>, iter_reference_t<I2>> &&
        predicate<F&, iter_common_reference_t<I1>, iter_common_reference_t<I2>>;

    template<class F, class I1, class I2 = I1>
    concept indirect_equivalence_relation =
        indirectly_readable<I1> && indirectly_readable<I2> &&
        copy_constructible<F> &&
        equivalence_relation<F&, indirect_value_t<I1>, indirect_value_t<I2>> &&
        equivalence_relation<F&, indirect_value_t<I1>, iter_reference_t<I2>> &&
        equivalence_relation<F&, iter_reference_t<I1>, indirect_value_t<I2>> &&
        equivalence_relation<F&, iter_reference_t<I1>, iter_reference_t<I2>> &&
        equivalence_relation<F&, iter_common_reference_t<I1>, iter_common_reference_t<I2>>;

    template<class F, class I1, class I2 = I1>
    concept indirect_strict_weak_order =
        indirectly_readable<I1> && indirectly_readable<I2> &&
        copy_constructible<F> &&
        strict_weak_order<F&, indirect_value_t<I1>, indirect_value_t<I2>> &&
        strict_weak_order<F&, indirect_value_t<I1>, iter_reference_t<I2>> &&
        strict_weak_order<F&, iter_reference_t<I1>, indirect_value_t<I2>> &&
        strict_weak_order<F&, iter_reference_t<I1>, iter_reference_t<I2>> &&
        strict_weak_order<F&, iter_common_reference_t<I1>, iter_common_reference_t<I2>>;

```

}

25.3.6.4 Class template projected**[projected]**

Class template `projected` is used to constrain algorithms that accept callable objects and projections (3.42). It combines an `indirectly_readable` type `I` and a callable object type `Proj` into a new `indirectly_readable` type whose reference type is the result of applying `Proj` to the `iter_reference_t` of `I`.

```
namespace std {
    template<indirectly_readable I, indirectly_regular_unary_invocable<I> Proj>
    struct projected {
        using value_type = remove_cvref_t<indirect_result_t<Proj&, I>>;
        indirect_result_t<Proj&, I> operator*() const;           // not defined
    };

    template<weakly_incrementable I, class Proj>
    struct incrementable_traits<projected<I, Proj>> {
        using difference_type = iter_difference_t<I>;
    };
}
```

25.3.7 Common algorithm requirements**[alg.req]****25.3.7.1 General****[alg.req.general]**

There are several additional iterator concepts that are commonly applied to families of algorithms. These group together iterator requirements of algorithm families. There are three relational concepts that specify how element values are transferred between `indirectly_readable` and `indirectly_writable` types: `indirectly_movable`, `indirectly_copyable`, and `indirectly_swappable`. There are three relational concepts for rearrangements: `permutable`, `mergeable`, and `sortable`. There is one relational concept for comparing values from different sequences: `indirectly_comparable`.

NOTE The `ranges::less` function object type used in the concepts below imposes constraints on the concepts' arguments in addition to those that appear in the concepts' bodies (22.10.9).

25.3.7.2 Concept `indirectly_movable`**[alg.req.ind.move]**

The `indirectly_movable` concept specifies the relationship between an `indirectly_readable` type and an `indirectly_writable` type between which values may be moved.

```
template<class In, class Out>
concept indirectly_movable =
    indirectly_readable<In> &&
    indirectly_writable<Out, iter_rvalue_reference_t<In>>;
```

The `indirectly_movable_storable` concept augments `indirectly_movable` with additional requirements enabling the transfer to be performed through an intermediate object of the `indirectly_readable` type's value type.

```
template<class In, class Out>
concept indirectly_movable_storable =
    indirectly_movable<In, Out> &&
    indirectly_writable<Out, iter_value_t<In>> &&
    movable<iter_value_t<In>> &&
    constructible_from<iter_value_t<In>, iter_rvalue_reference_t<In>> &&
    assignable_from<iter_value_t<In>&, iter_rvalue_reference_t<In>>;
```

Let `i` be a dereferenceable value of type `In`. `In` and `Out` model `indirectly_movable_storable<In, Out>` only if after the initialization of the object `obj` in

```
iter_value_t<In> obj(ranges::iter_move(i));
```

`obj` is equal to the value previously denoted by `*i`. If `iter_rvalue_reference_t<In>` is an rvalue reference type, the resulting state of the value denoted by `*i` is valid but unspecified (16.4.6.15).

25.3.7.3 Concept `indirectly_copyable`**[alg.req.ind.copy]**

The `indirectly_copyable` concept specifies the relationship between an `indirectly_readable` type and an `indirectly_writable` type between which values may be copied.

```
template<class In, class Out>
concept indirectly_copyable =
    indirectly_readable<In> &&
    indirectly_writable<Out, iter_reference_t<In>>;
```

The `indirectly_copyable_storable` concept augments `indirectly_copyable` with additional requirements enabling the transfer to be performed through an intermediate object of the `indirectly_readable` type's value type. It also requires the capability to make copies of values.

```
template<class In, class Out>
concept indirectly_copyable_storable =
    indirectly_copyable<In, Out> &&
    indirectly_writable<Out, iter_value_t<In>&> &&
    indirectly_writable<Out, const iter_value_t<In>&> &&
    indirectly_writable<Out, iter_value_t<In>&&> &&
    indirectly_writable<Out, const iter_value_t<In>&&> &&
    copyable<iter_value_t<In>> &&
    constructible_from<iter_value_t<In>, iter_reference_t<In>> &&
    assignable_from<iter_value_t<In>&, iter_reference_t<In>>;
```

Let `i` be a dereferenceable value of type `In`. `In` and `Out` model `indirectly_copyable_storable<In, Out>` only if after the initialization of the object `obj` in

```
iter_value_t<In> obj(*i);
```

`obj` is equal to the value previously denoted by `*i`. If `iter_reference_t<In>` is an rvalue reference type, the resulting state of the value denoted by `*i` is valid but unspecified (16.4.6.15).

25.3.7.4 Concept `indirectly_swappable`

[alg.req.ind.swap]

The `indirectly_swappable` concept specifies a swappable relationship between the values referenced by two `indirectly_readable` types.

```
template<class I1, class I2 = I1>
concept indirectly_swappable =
    indirectly_readable<I1> && indirectly_readable<I2> &&
    requires(const I1 i1, const I2 i2) {
        ranges::iter_swap(i1, i1);
        ranges::iter_swap(i2, i2);
        ranges::iter_swap(i1, i2);
        ranges::iter_swap(i2, i1);
    };
};
```

25.3.7.5 Concept `indirectly_comparable`

[alg.req.ind.cmp]

The `indirectly_comparable` concept specifies the common requirements of algorithms that compare values from two different sequences.

```
template<class I1, class I2, class R, class P1 = identity,
         class P2 = identity>
concept indirectly_comparable =
    indirect_binary_predicate<R, projected<I1, P1>, projected<I2, P2>>;
```

25.3.7.6 Concept `permutable`

[alg.req.permutable]

The `permutable` concept specifies the common requirements of algorithms that reorder elements in place by moving or swapping them.

```
template<class I>
concept permutable =
    forward_iterator<I> &&
    indirectly_movable_storable<I, I> &&
    indirectly_swappable<I, I>;
```

25.3.7.7 Concept `mergeable`

[alg.req.mergeable]

The `mergeable` concept specifies the requirements of algorithms that merge sorted sequences into an output sequence by copying elements.

```
template<class I1, class I2, class Out, class R = ranges::less,
        class P1 = identity, class P2 = identity>
concept mergeable =
    input_iterator<I1> &&
    input_iterator<I2> &&
    weakly_incrementable<Out> &&
    indirectly_copyable<I1, Out> &&
    indirectly_copyable<I2, Out> &&
    indirect_strict_weak_order<R, projected<I1, P1>, projected<I2, P2>>;
```

25.3.7.8 Concept sortable

[alg.req.sortable]

The `sortable` concept specifies the common requirements of algorithms that permute sequences into ordered sequences (e.g., `sort`).

```
template<class I, class R = ranges::less, class P = identity>
concept sortable =
    permutable<I> &&
    indirect_strict_weak_order<R, projected<I, P>>;
```

25.4 Iterator primitives

[iterator.primitives]

25.4.1 General

[iterator.primitives.general]

To simplify the use of iterators, the library provides several classes and functions.

25.4.2 Standard iterator tags

[std.iterator.tags]

It is often desirable for a function template specialization to find out what is the most specific category of its iterator argument, so that the function can select the most efficient algorithm at compile time. To facilitate this, the library introduces *category tag* classes which are used as compile time tags for algorithm selection. They are: `output_iterator_tag`, `input_iterator_tag`, `forward_iterator_tag`, `bidirectional_iterator_tag`, `random_access_iterator_tag`, and `contiguous_iterator_tag`. For every iterator of type `I`, `iterator_traits<I>::iterator_category` shall be defined to be a category tag that describes the iterator's behavior. Additionally, `iterator_traits<I>::iterator_concept` may be used to indicate conformance to the iterator concepts (25.3.4).

```
namespace std {
    struct output_iterator_tag { };
    struct input_iterator_tag { };
    struct forward_iterator_tag: public input_iterator_tag { };
    struct bidirectional_iterator_tag: public forward_iterator_tag { };
    struct random_access_iterator_tag: public bidirectional_iterator_tag { };
    struct contiguous_iterator_tag: public random_access_iterator_tag { };
}
```

EXAMPLE 1 A program-defined iterator `BinaryTreeIterator` can be included into the bidirectional iterator category by specializing the `iterator_traits` template:

```
template<class T> struct iterator_traits<BinaryTreeIterator<T>> {
    using iterator_category = bidirectional_iterator_tag;
    using difference_type   = ptrdiff_t;
    using value_type        = T;
    using pointer           = T*;
    using reference         = T&;
};
```

EXAMPLE 2 If `evolve()` is well-defined for bidirectional iterators, but can be implemented more efficiently for random access iterators, then the implementation is as follows:

```
template<class BidirectionalIterator>
inline void
evolve(BidirectionalIterator first, BidirectionalIterator last) {
    evolve(first, last,
        typename iterator_traits<BidirectionalIterator>::iterator_category());
}
```

```

template<class BidirectionalIterator>
void evolve(BidirectionalIterator first, BidirectionalIterator last,
    bidirectional_iterator_tag) {
    // more generic, but less efficient algorithm
}

template<class RandomAccessIterator>
void evolve(RandomAccessIterator first, RandomAccessIterator last,
    random_access_iterator_tag) {
    // more efficient, but less generic algorithm
}

```

25.4.3 Iterator operations

[iterator.operations]

Since only random access iterators provide + and - operators, the library provides two function templates `advance` and `distance`. These function templates use + and - for random access iterators (and are, therefore, constant time for them); for input, forward and bidirectional iterators they use ++ to provide linear time implementations.

```

template<class InputIterator, class Distance>
constexpr void advance(InputIterator& i, Distance n);

```

Preconditions: `n` is negative only for bidirectional iterators.

Effects: Increments `i` by `n` if `n` is non-negative, and decrements `i` by `-n` otherwise.

```

template<class InputIterator>
constexpr typename iterator_traits<InputIterator>::difference_type
distance(InputIterator first, InputIterator last);

```

Preconditions: `last` is reachable from `first`, or `InputIterator` meets the *Cpp17RandomAccessIterator* requirements and `first` is reachable from `last`.

Effects: If `InputIterator` meets the *Cpp17RandomAccessIterator* requirements, returns `(last - first)`; otherwise, increments `first` until `last` is reached and returns the number of increments.

```

template<class InputIterator>
constexpr InputIterator next(InputIterator x,
    typename iterator_traits<InputIterator>::difference_type n = 1);

```

Effects: Equivalent to: `advance(x, n); return x;`

```

template<class BidirectionalIterator>
constexpr BidirectionalIterator prev(BidirectionalIterator x,
    typename iterator_traits<BidirectionalIterator>::difference_type n = 1);

```

Effects: Equivalent to: `advance(x, -n); return x;`

25.4.4 Range iterator operations

[range.iter.ops]

25.4.4.1 General

[range.iter.ops.general]

The library includes the function templates `ranges::advance`, `ranges::distance`, `ranges::next`, and `ranges::prev` to manipulate iterators. These operations adapt to the set of operators provided by each iterator category to provide the most efficient implementation possible for a concrete iterator type.

EXAMPLE 1 `ranges::advance` uses the + operator to move a `random_access_iterator` forward `n` steps in constant time. For an iterator type that does not model `random_access_iterator`, `ranges::advance` instead performs `n` individual increments with the ++ operator.

The function templates defined in 25.4.4 are not found by argument-dependent name lookup (6.5.4). When found by unqualified (6.5.3) name lookup for the *postfix-expression* in a function call (7.6.1.3), they inhibit argument-dependent name lookup.

EXAMPLE 2

```

void foo() {
    using namespace std::ranges;
    std::vector<int> vec{1,2,3};
    distance(begin(vec), end(vec));    // #1
}

```

The function call expression at #1 invokes `std::ranges::distance`, not `std::distance`, despite that (a) the iterator type returned from `begin(vec)` and `end(vec)` may be associated with namespace `std` and (b) `std::distance` is more specialized (13.7.7.3) than `std::ranges::distance` since the former requires its first two parameters to have the same type.

The number and order of deducible template parameters for the function templates defined in 25.4.4 is unspecified, except where explicitly stated otherwise.

25.4.4.2 `ranges::advance`

[range.iter.op.advance]

```
template<input_or_output_iterator I>
constexpr void ranges::advance(I& i, iter_difference_t<I> n);
```

Preconditions: If `I` does not model `bidirectional_iterator`, `n` is not negative.

Effects:

- If `I` models `random_access_iterator`, equivalent to `i += n`.
- Otherwise, if `n` is non-negative, increments `i` by `n`.
- Otherwise, decrements `i` by `-n`.

```
template<input_or_output_iterator I, sentinel_for<I> S>
constexpr void ranges::advance(I& i, S bound);
```

Preconditions: Either `assignable_from<I&, S> || sized_sentinel_for<S, I>` is modeled, or `[i, bound)` denotes a range.

Effects:

- If `I` and `S` model `assignable_from<I&, S>`, equivalent to `i = std::move(bound)`.
- Otherwise, if `S` and `I` model `sized_sentinel_for<S, I>`, equivalent to `ranges::advance(i, bound - i)`.
- Otherwise, while `bool(i != bound)` is true, increments `i`.

```
template<input_or_output_iterator I, sentinel_for<I> S>
constexpr iter_difference_t<I> ranges::advance(I& i, iter_difference_t<I> n, S bound);
```

Preconditions: If `n > 0`, `[i, bound)` denotes a range. If `n == 0`, `[i, bound)` or `[bound, i)` denotes a range. If `n < 0`, `[bound, i)` denotes a range, `I` models `bidirectional_iterator`, and `I` and `S` model `same_as<I, S>`.

Effects:

- If `S` and `I` model `sized_sentinel_for<S, I>`:
 - If $|n| \geq |bound - i|$, equivalent to `ranges::advance(i, bound)`.
 - Otherwise, equivalent to `ranges::advance(i, n)`.
- Otherwise,
 - if `n` is non-negative, while `bool(i != bound)` is true, increments `i` but at most `n` times.
 - Otherwise, while `bool(i != bound)` is true, decrements `i` but at most `-n` times.

Returns: `n - M`, where `M` is the difference between the ending and starting positions of `i`.

25.4.4.3 `ranges::distance`

[range.iter.op.distance]

```
template<class I, sentinel_for<I> S>
requires (!sized_sentinel_for<S, I>)
constexpr iter_difference_t<I> ranges::distance(I first, S last);
```

Preconditions: `[first, last)` denotes a range.

Effects: Increments `first` until `last` is reached and returns the number of increments.

```
template<class I, sized_sentinel_for<decay_t<I>> S>
constexpr iter_difference_t<decay_t<I>> ranges::distance(I&& first, S last);

Effects: Equivalent to: return last - static_cast<const decay_t<I>&>(first);
```

```
template<range R>
constexpr range_difference_t<R> ranges::distance(R&& r);
    Effects: If R models sized_range, equivalent to:
        return static_cast<range_difference_t<R>>(ranges::size(r));    // 26.3.10
    Otherwise, equivalent to:
        return ranges::distance(ranges::begin(r), ranges::end(r));    // 26.3
```

25.4.4.4 ranges::next [range.iter.op.next]

```
template<input_or_output_iterator I>
constexpr I ranges::next(I x);
    Effects: Equivalent to: ++x; return x;

template<input_or_output_iterator I>
constexpr I ranges::next(I x, iter_difference_t<I> n);
    Effects: Equivalent to: ranges::advance(x, n); return x;

template<input_or_output_iterator I, sentinel_for<I> S>
constexpr I ranges::next(I x, S bound);
    Effects: Equivalent to: ranges::advance(x, bound); return x;

template<input_or_output_iterator I, sentinel_for<I> S>
constexpr I ranges::next(I x, iter_difference_t<I> n, S bound);
    Effects: Equivalent to: ranges::advance(x, n, bound); return x;
```

25.4.4.5 ranges::prev [range.iter.op.prev]

```
template<bidirectional_iterator I>
constexpr I ranges::prev(I x);
    Effects: Equivalent to: --x; return x;

template<bidirectional_iterator I>
constexpr I ranges::prev(I x, iter_difference_t<I> n);
    Effects: Equivalent to: ranges::advance(x, -n); return x;

template<bidirectional_iterator I>
constexpr I ranges::prev(I x, iter_difference_t<I> n, I bound);
    Effects: Equivalent to: ranges::advance(x, -n, bound); return x;
```

25.5 Iterator adaptors [predef.iterators]

25.5.1 Reverse iterators [reverse.iterators]

25.5.1.1 General [reverse.iterators.general]

Class template `reverse_iterator` is an iterator adaptor that iterates from the end of the sequence defined by its underlying iterator to the beginning of that sequence.

25.5.1.2 Class template `reverse_iterator` [reverse.iterator]

```
namespace std {
    template<class Iterator>
    class reverse_iterator {
    public:
        using iterator_type      = Iterator;
        using iterator_concept   = see below;
        using iterator_category   = see below;
        using value_type         = iter_value_t<Iterator>;
        using difference_type     = iter_difference_t<Iterator>;
        using pointer             = typename iterator_traits<Iterator>::pointer;
        using reference           = iter_reference_t<Iterator>;
```

```

constexpr reverse_iterator();
constexpr explicit reverse_iterator(Iterator x);
template<class U> constexpr reverse_iterator(const reverse_iterator<U>& u);
template<class U> constexpr reverse_iterator& operator=(const reverse_iterator<U>& u);

constexpr Iterator base() const;
constexpr reference operator*() const;
constexpr pointer operator->() const requires see below;

constexpr reverse_iterator& operator++();
constexpr reverse_iterator operator++(int);
constexpr reverse_iterator& operator--();
constexpr reverse_iterator operator--(int);

constexpr reverse_iterator operator+ (difference_type n) const;
constexpr reverse_iterator& operator+=(difference_type n);
constexpr reverse_iterator operator- (difference_type n) const;
constexpr reverse_iterator& operator-=(difference_type n);
constexpr unspecified operator[] (difference_type n) const;

friend constexpr iter_rvalue_reference_t<Iterator>
    iter_move(const reverse_iterator& i) noexcept(see below);
template<indirectly_swappable<Iterator> Iterator2>
    friend constexpr void
        iter_swap(const reverse_iterator& x,
            const reverse_iterator<Iterator2>& y) noexcept(see below);

protected:
    Iterator current;
};
}

```

The member *typedef-name* `iterator_concept` denotes

- `random_access_iterator_tag` if `Iterator` models `random_access_iterator`, and
- `bidirectional_iterator_tag` otherwise.

The member *typedef-name* `iterator_category` denotes

- `random_access_iterator_tag` if the type `iterator_traits<Iterator>::iterator_category` models `derived_from<random_access_iterator_tag>`, and
- `iterator_traits<Iterator>::iterator_category` otherwise.

25.5.1.3 Requirements [reverse.iter.requirements]

The template parameter `Iterator` shall either meet the requirements of a *Cpp17BidirectionalIterator* (25.3.5.6) or model `bidirectional_iterator` (25.3.4.12).

Additionally, `Iterator` shall either meet the requirements of a *Cpp17RandomAccessIterator* (25.3.5.7) or model `random_access_iterator` (25.3.4.13) if the definitions of any of the members

- `operator+`, `operator-`, `operator+=`, `operator-=` (25.5.1.7), or
- `operator[]` (25.5.1.6),

or the non-member operators (25.5.1.8)

- `operator<`, `operator>`, `operator<=`, `operator>=`, `operator-`, or `operator+` (25.5.1.9)

are instantiated (13.9.2).

25.5.1.4 Construction and assignment [reverse.iter.cons]

```
constexpr reverse_iterator();
```

Effects: Value-initializes `current`. Iterator operations applied to the resulting iterator have defined behavior if and only if the corresponding operations are defined on a value-initialized iterator of type `Iterator`.

```
constexpr explicit reverse_iterator(Iterator x);
```

Effects: Initializes current with x.

```
template<class U> constexpr reverse_iterator(const reverse_iterator<U>& u);
```

Constraints: `is_same_v<U, Iterator>` is false and `const U&` models `convertible_to<Iterator>`.

Effects: Initializes current with `u.current`.

```
template<class U>
```

```
constexpr reverse_iterator&
```

```
operator=(const reverse_iterator<U>& u);
```

Constraints: `is_same_v<U, Iterator>` is false, `const U&` models `convertible_to<Iterator>`, and `assignable_from<Iterator&, const U&>` is modeled.

Effects: Assigns `u.current` to current.

Returns: `*this`.

25.5.1.5 Conversion

[reverse.iter.conv]

```
constexpr Iterator base() const;
```

Returns: current.

25.5.1.6 Element access

[reverse.iter.elem]

```
constexpr reference operator*() const;
```

Effects: As if by:

```
Iterator tmp = current;
return *--tmp;
```

```
constexpr pointer operator->() const
```

```
requires (is_pointer_v<Iterator> ||
requires(const Iterator i) { i.operator->(); });
```

Effects:

- If `Iterator` is a pointer type, equivalent to: `return prev(current);`
- Otherwise, equivalent to: `return prev(current).operator->();`

```
constexpr unspecified operator[](difference_type n) const;
```

Returns: `current[-n-1]`.

25.5.1.7 Navigation

[reverse.iter.nav]

```
constexpr reverse_iterator operator+(difference_type n) const;
```

Returns: `reverse_iterator(current-n)`.

```
constexpr reverse_iterator operator-(difference_type n) const;
```

Returns: `reverse_iterator(current+n)`.

```
constexpr reverse_iterator& operator++();
```

Effects: As if by: `--current;`

Returns: `*this`.

```
constexpr reverse_iterator operator++(int);
```

Effects: As if by:

```
reverse_iterator tmp = *this;
--current;
return tmp;
```

```
constexpr reverse_iterator& operator--();
```

Effects: As if by ++current.

Returns: *this.

```
constexpr reverse_iterator operator--(int);
```

Effects: As if by:

```
reverse_iterator tmp = *this;
++current;
return tmp;
```

```
constexpr reverse_iterator& operator+=(difference_type n);
```

Effects: As if by: current -= n;

Returns: *this.

```
constexpr reverse_iterator& operator-=(difference_type n);
```

Effects: As if by: current += n;

Returns: *this.

25.5.1.8 Comparisons

[reverse.iter.cmp]

```
template<class Iterator1, class Iterator2>
```

```
constexpr bool operator==(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

Constraints: x.base() == y.base() is well-formed and convertible to bool.

Returns: x.base() == y.base().

```
template<class Iterator1, class Iterator2>
```

```
constexpr bool operator!=(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

Constraints: x.base() != y.base() is well-formed and convertible to bool.

Returns: x.base() != y.base().

```
template<class Iterator1, class Iterator2>
```

```
constexpr bool operator<(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

Constraints: x.base() > y.base() is well-formed and convertible to bool.

Returns: x.base() > y.base().

```
template<class Iterator1, class Iterator2>
```

```
constexpr bool operator>(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

Constraints: x.base() < y.base() is well-formed and convertible to bool.

Returns: x.base() < y.base().

```
template<class Iterator1, class Iterator2>
```

```
constexpr bool operator<=(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

Constraints: x.base() >= y.base() is well-formed and convertible to bool.

Returns: x.base() >= y.base().

```
template<class Iterator1, class Iterator2>
constexpr bool operator==(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

Constraints: $x.base() \leq y.base()$ is well-formed and convertible to bool.

Returns: $x.base() \leq y.base()$.

```
template<class Iterator1, three_way_comparable_with<Iterator1> Iterator2>
constexpr compare_three_way_result_t<Iterator1, Iterator2>
operator<=>(const reverse_iterator<Iterator1>& x,
           const reverse_iterator<Iterator2>& y);
```

Returns: $y.base() \leq x.base()$.

NOTE The argument order in the *Returns:* element is reversed because this is a reverse iterator.

25.5.1.9 Non-member functions

[reverse.iter.nonmember]

```
template<class Iterator1, class Iterator2>
constexpr auto operator-(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y) -> decltype(y.base() - x.base());
```

Returns: $y.base() - x.base()$.

```
template<class Iterator>
constexpr reverse_iterator<Iterator> operator+(
    iter_difference_t<Iterator> n,
    const reverse_iterator<Iterator>& x);
```

Returns: $reverse\_iterator<Iterator>(x.base() - n)$.

```
friend constexpr iter_rvalue_reference_t<Iterator>
iter_move(const reverse_iterator& i) noexcept(see below);
```

Effects: Equivalent to:

```
auto tmp = i.base();
return ranges::iter_move(--tmp);
```

Remarks: The exception specification is equivalent to:

```
is_nothrow_copy_constructible_v<Iterator> &&
noexcept(ranges::iter_move(--declval<Iterator&>()))
```

```
template<indirectly_swappable<Iterator> Iterator2>
friend constexpr void
iter_swap(const reverse_iterator& x,
           const reverse_iterator<Iterator2>& y) noexcept(see below);
```

Effects: Equivalent to:

```
auto xtmp = x.base();
auto ytmp = y.base();
ranges::iter_swap(--xtmp, --ytmp);
```

Remarks: The exception specification is equivalent to:

```
is_nothrow_copy_constructible_v<Iterator> &&
is_nothrow_copy_constructible_v<Iterator2> &&
noexcept(ranges::iter_swap(--declval<Iterator&>(), --declval<Iterator2&>()))
```

```
template<class Iterator>
constexpr reverse_iterator<Iterator> make_reverse_iterator(Iterator i);
```

Returns: $reverse\_iterator<Iterator>(i)$.

25.5.2 Insert iterators

[insert.iterators]

25.5.2.1 General

[insert.iterators.general]

To make it possible to deal with insertion in the same way as writing into an array, a special kind of iterator adaptors, called *insert iterators*, are provided in the library. With regular iterator classes,

```
while (first != last) *result++ = *first++;
```

causes a range `[first,last)` to be copied into a range starting with `result`. The same code with `result` being an insert iterator will insert corresponding elements into the container. This device allows all of the copying algorithms in the library to work in the *insert mode* instead of the *regular overwrite mode*.

An insert iterator is constructed from a container and possibly one of its iterators pointing to where insertion takes place if it is neither at the beginning nor at the end of the container. Insert iterators meet the requirements of output iterators. `operator*` returns the insert iterator itself. The assignment `operator=(const T& x)` is defined on insert iterators to allow writing into them, it inserts `x` right before where the insert iterator is pointing. In other words, an insert iterator is like a cursor pointing into the container where the insertion takes place. `back_insert_iterator` inserts elements at the end of a container, `front_insert_iterator` inserts elements at the beginning of a container, and `insert_iterator` inserts elements where the iterator points to in a container. `back_inserter`, `front_inserter`, and `inserter` are three functions making the insert iterators out of a container.

25.5.2.2 Class template `back_insert_iterator`

[back.insert.iterator]

25.5.2.2.1 General

[back.insert.iter.general]

```
namespace std {
    template<class Container>
    class back_insert_iterator {
    protected:
        Container* container;

    public:
        using iterator_category = output_iterator_tag;
        using value_type        = void;
        using difference_type    = ptrdiff_t;
        using pointer            = void;
        using reference          = void;
        using container_type     = Container;

        constexpr explicit back_insert_iterator(Container& x);
        constexpr back_insert_iterator& operator=(const typename Container::value_type& value);
        constexpr back_insert_iterator& operator=(typename Container::value_type&& value);

        constexpr back_insert_iterator& operator*();
        constexpr back_insert_iterator& operator++();
        constexpr back_insert_iterator operator++(int);
    };
}
```

25.5.2.2.2 Operations

[back.insert.iter.ops]

```
constexpr explicit back_insert_iterator(Container& x);
```

Effects: Initializes container with `addressof(x)`.

```
constexpr back_insert_iterator& operator=(const typename Container::value_type& value);
```

Effects: As if by: `container->push_back(value)`;

Returns: `*this`.

```
constexpr back_insert_iterator& operator=(typename Container::value_type&& value);
```

Effects: As if by: `container->push_back(std::move(value))`;

Returns: `*this`.

```
constexpr back_insert_iterator& operator*();
```

Returns: `*this`.

```
constexpr back_insert_iterator& operator++();
```

```
constexpr back_insert_iterator operator++(int);
```

Returns: `*this`.

25.5.2.2.3 back_inserter**[back.inserter]**

```
template<class Container>
constexpr back_insert_iterator<Container> back_inserter(Container& x);
```

Returns: back_insert_iterator<Container>(x).

25.5.2.3 Class template front_insert_iterator**[front.insert.iterator]****25.5.2.3.1 General****[front.insert.iter.general]**

```
namespace std {
    template<class Container>
    class front_insert_iterator {
    protected:
        Container* container;

    public:
        using iterator_category = output_iterator_tag;
        using value_type        = void;
        using difference_type    = ptrdiff_t;
        using pointer            = void;
        using reference          = void;
        using container_type     = Container;

        constexpr explicit front_insert_iterator(Container& x);
        constexpr front_insert_iterator& operator=(const typename Container::value_type& value);
        constexpr front_insert_iterator& operator=(typename Container::value_type&& value);

        constexpr front_insert_iterator& operator*();
        constexpr front_insert_iterator& operator++();
        constexpr front_insert_iterator operator++(int);
    };
}
```

25.5.2.3.2 Operations**[front.insert.iter.ops]**

```
constexpr explicit front_insert_iterator(Container& x);
```

Effects: Initializes container with addressof(x).

```
constexpr front_insert_iterator& operator=(const typename Container::value_type& value);
```

Effects: As if by: container->push_front(value);

Returns: *this.

```
constexpr front_insert_iterator& operator=(typename Container::value_type&& value);
```

Effects: As if by: container->push_front(std::move(value));

Returns: *this.

```
constexpr front_insert_iterator& operator*();
```

Returns: *this.

```
constexpr front_insert_iterator& operator++();
constexpr front_insert_iterator operator++(int);
```

Returns: *this.

25.5.2.3.3 front_inserter**[front.inserter]**

```
template<class Container>
constexpr front_insert_iterator<Container> front_inserter(Container& x);
```

Returns: front_insert_iterator<Container>(x).

25.5.2.4 Class template insert_iterator

[insert.iterator]

25.5.2.4.1 General

[insert.iter.general]

```

namespace std {
    template<class Container>
    class insert_iterator {
    protected:
        Container* container;
        ranges::iterator_t<Container> iter;

    public:
        using iterator_category = output_iterator_tag;
        using value_type        = void;
        using difference_type    = ptrdiff_t;
        using pointer            = void;
        using reference          = void;
        using container_type     = Container;

        constexpr insert_iterator(Container& x, ranges::iterator_t<Container> i);
        constexpr insert_iterator& operator=(const typename Container::value_type& value);
        constexpr insert_iterator& operator=(typename Container::value_type&& value);

        constexpr insert_iterator& operator*();
        constexpr insert_iterator& operator++();
        constexpr insert_iterator& operator++(int);
    };
}

```

25.5.2.4.2 Operations

[insert.iter.ops]

```
constexpr insert_iterator(Container& x, ranges::iterator_t<Container> i);
```

Effects: Initializes container with `addressof(x)` and iter with `i`.

```
constexpr insert_iterator& operator=(const typename Container::value_type& value);
```

Effects: As if by:

```

    iter = container->insert(iter, value);
    ++iter;

```

Returns: `*this`.

```
constexpr insert_iterator& operator=(typename Container::value_type&& value);
```

Effects: As if by:

```

    iter = container->insert(iter, std::move(value));
    ++iter;

```

Returns: `*this`.

```
constexpr insert_iterator& operator*();
```

Returns: `*this`.

```
constexpr insert_iterator& operator++();
```

```
constexpr insert_iterator& operator++(int);
```

Returns: `*this`.

25.5.2.4.3 inserter

[inserter]

```

template<class Container>
constexpr insert_iterator<Container>
    inserter(Container& x, ranges::iterator_t<Container> i);

    Returns: insert_iterator<Container>(x, i).

```

25.5.3 Constant iterators and sentinels**[const.iterators]****25.5.3.1 General****[const.iterators.general]**

Class template `basic_const_iterator` is an iterator adaptor with the same behavior as the underlying iterator except that its indirection operator implicitly converts the value returned by the underlying iterator's indirection operator to a type such that the adapted iterator is a constant iterator (25.3). Some generic algorithms can be called with constant iterators to avoid mutation.

Specializations of `basic_const_iterator` are constant iterators.

25.5.3.2 Alias templates**[const.iterators.alias]**

```
template<indirectly_readable It>
    using iter_const_reference_t =
        common_reference_t<const iter_value_t<It>&&, iter_reference_t<It>>;

template<class It>
    concept constant_iterator = // exposition only
        input_iterator<It> && same_as<iter_const_reference_t<It>, iter_reference_t<It>>;

template<input_iterator I>
    using const_iterator = see below;

    Result: If I models constant_iterator, I. Otherwise, basic_const_iterator<I>.

template<semiregular S>
    using const_sentinel = see below;

    Result: If S models input_iterator, const_iterator<S>. Otherwise, S.
```

25.5.3.3 Class template basic_const_iterator**[const.iterators.iterator]**

```
namespace std {
    template<class I>
        concept not_a_const_iterator = see below; // exposition only

    template<indirectly_readable I>
        using iter_const_rvalue_reference_t = // exposition only
            common_reference_t<const iter_value_t<I>&&, iter_rvalue_reference_t<I>>;

    template<input_iterator Iterator>
    class basic_const_iterator {
        Iterator current_ = Iterator(); // exposition only
        using reference = iter_const_reference_t<Iterator>; // exposition only
        using rvalue_reference = // exposition only
            iter_const_rvalue_reference_t<Iterator>;

    public:
        using iterator_concept = see below;
        using iterator_category = see below; // not always present
        using value_type = iter_value_t<Iterator>;
        using difference_type = iter_difference_t<Iterator>;

        basic_const_iterator() requires default_initializable<Iterator> = default;
        constexpr basic_const_iterator(Iterator current);

}
};
}

```

Given some type *I*, the concept *not-a-const-iterator* is defined as *false* if *I* is a specialization of *basic_const_iterator* and *true* otherwise.

25.5.3.4 Member types

[const.iterators.types]

basic_const_iterator<*Iterator*>::*iterator_concept* is defined as follows:

- If *Iterator* models *contiguous_iterator*, then *iterator_concept* denotes *contiguous_iterator_tag*.
- Otherwise, if *Iterator* models *random_access_iterator*, then *iterator_concept* denotes *random_access_iterator_tag*.
- Otherwise, if *Iterator* models *bidirectional_iterator*, then *iterator_concept* denotes *bidirectional_iterator_tag*.
- Otherwise, if *Iterator* models *forward_iterator*, then *iterator_concept* denotes *forward_iterator_tag*.
- Otherwise, *iterator_concept* denotes *input_iterator_tag*.

The member *typedef-name* *iterator_category* is defined if and only if *Iterator* models *forward_iterator*. In that case, *basic_const_iterator*<*Iterator*>::*iterator_category* denotes the type *iterator_traits*<*Iterator*>::*iterator_category*.

25.5.3.5 Operations

[const.iterators.ops]

```

constexpr basic_const_iterator(Iterator current);
    Effects: Initializes current_ with std::move(current).

template< convertible_to<Iterator> U>
    constexpr basic_const_iterator(basic_const_iterator<U> current);
    Effects: Initializes current_ with std::move(current.current_).

template< different-from<basic_const_iterator> T>
    requires convertible_to<T, Iterator>
    constexpr basic_const_iterator(T&& current);
    Effects: Initializes current_ with std::forward<T>(current).

constexpr const Iterator& base() const & noexcept;
    Effects: Equivalent to: return current_;

constexpr Iterator base() &&;
    Effects: Equivalent to: return std::move(current_);

```

```
constexpr reference operator*() const;
```

Effects: Equivalent to: `return static_cast<reference>(*current_);`

```
constexpr const auto* operator->() const
```

```
requires is_lvalue_reference_v<iter_reference_t<Iterator>> &&  
       same_as<remove_cvref_t<iter_reference_t<Iterator>>, value_type>;
```

Returns: If `Iterator` models `contiguous_iterator`, `to_address(current_)`; otherwise, `address-of(*current_)`.

```
constexpr basic_const_iterator& operator++();
```

Effects: Equivalent to:

```
++current_  
return *this;
```

```
constexpr void operator++(int);
```

Effects: Equivalent to: `++current_;`

```
constexpr basic_const_iterator operator++(int) requires forward_iterator<Iterator>;
```

Effects: Equivalent to:

```
auto tmp = *this;  
++*this;  
return tmp;
```

```
constexpr basic_const_iterator& operator--() requires bidirectional_iterator<Iterator>;
```

Effects: Equivalent to:

```
--current_  
return *this;
```

```
constexpr basic_const_iterator operator--(int) requires bidirectional_iterator<Iterator>;
```

Effects: Equivalent to:

```
auto tmp = *this;  
--*this;  
return tmp;
```

```
constexpr basic_const_iterator& operator+=(difference_type n)
```

```
requires random_access_iterator<Iterator>;
```

```
constexpr basic_const_iterator& operator-=(difference_type n)
```

```
requires random_access_iterator<Iterator>;
```

Let *op* be the operator.

Effects: Equivalent to:

```
current_ op n;  
return *this;
```

```
constexpr reference operator[](difference_type n) const requires random_access_iterator<Iterator>
```

Effects: Equivalent to: `return static_cast<reference>(current_[n]);`

```
template<sentinel_for<Iterator> S>
```

```
constexpr bool operator==(const S& s) const;
```

Effects: Equivalent to: `return current_ == s;`

```
constexpr bool operator<(const basic_const_iterator& y) const
```

```
requires random_access_iterator<Iterator>;
```

```
constexpr bool operator>(const basic_const_iterator& y) const
```

```
requires random_access_iterator<Iterator>;
```

```
constexpr bool operator<=(const basic_const_iterator& y) const
```

```
requires random_access_iterator<Iterator>;
```

```
constexpr bool operator>=(const basic_const_iterator& y) const
```

```
requires random_access_iterator<Iterator>;
```

```
constexpr auto operator<=>(const basic_const_iterator& y) const
    requires random_access_iterator<Iterator> && three_way_comparable<Iterator>;
```

Let *op* be the operator.

Effects: Equivalent to: return *current_ op y.current_*;

```
template<different-from<basic_const_iterator> I>
    constexpr bool operator<(const I& y) const
        requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
template<different-from<basic_const_iterator> I>
    constexpr bool operator>(const I& y) const
        requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
template<different-from<basic_const_iterator> I>
    constexpr bool operator<=(const I& y) const
        requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
template<different-from<basic_const_iterator> I>
    constexpr bool operator>=(const I& y) const
        requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
template<different-from<basic_const_iterator> I>
    constexpr auto operator<=>(const I& y) const
        requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I> &&
            three_way_comparable_with<Iterator, I>;
```

Let *op* be the operator.

Effects: Equivalent to: return *current_ op y*;

```
template<not-a-const-iterator I>
    friend constexpr bool operator<(const I& x, const basic_const_iterator& y)
        requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
template<not-a-const-iterator I>
    friend constexpr bool operator>(const I& x, const basic_const_iterator& y)
        requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
template<not-a-const-iterator I>
    friend constexpr bool operator<=(const I& x, const basic_const_iterator& y)
        requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
template<not-a-const-iterator I>
    friend constexpr bool operator>=(const I& x, const basic_const_iterator& y)
        requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
```

Let *op* be the operator.

Returns: Equivalent to: return *x op y.current_*;

```
friend constexpr basic_const_iterator operator+(const basic_const_iterator& i, difference_type n)
    requires random_access_iterator<Iterator>;
friend constexpr basic_const_iterator operator+(difference_type n, const basic_const_iterator& i)
    requires random_access_iterator<Iterator>;
```

Effects: Equivalent to: return *basic_const_iterator(i.current_ + n)*;

```
friend constexpr basic_const_iterator operator-(const basic_const_iterator& i, difference_type n)
    requires random_access_iterator<Iterator>;
```

Effects: Equivalent to: return *basic_const_iterator(i.current_ - n)*;

```
template<sized_sentinel_for<Iterator> S>
    constexpr difference_type operator-(const S& y) const;
```

Effects: Equivalent to: return *current_ - y*;

```
template<not-a-const-iterator S>
    requires sized_sentinel_for<S, Iterator>
    friend constexpr difference_type operator-(const S& x, const basic_const_iterator& y);
```

Effects: Equivalent to: return *x - y.current_*;

25.5.4 Move iterators and sentinels

[move.iterators]

25.5.4.1 General

[move.iterators.general]

Class template `move_iterator` is an iterator adaptor with the same behavior as the underlying iterator except that its indirection operator implicitly converts the value returned by the underlying iterator's indirection operator to an rvalue. Some generic algorithms can be called with move iterators to replace copying with moving.

EXAMPLE

```
list<string> s;
// populate the list s
vector<string> v1(s.begin(), s.end()); // copies strings into v1
vector<string> v2(make_move_iterator(s.begin()),
                 make_move_iterator(s.end())); // moves strings into v2
```

25.5.4.2 Class template `move_iterator`

[move.iterator]

```
namespace std {
    template<class Iterator>
    class move_iterator {
    public:
        using iterator_type      = Iterator;
        using iterator_concept   = see below;
        using iterator_category   = see below; // not always present
        using value_type         = iter_value_t<Iterator>;
        using difference_type     = iter_difference_t<Iterator>;
        using pointer             = Iterator;
        using reference           = iter_rvalue_reference_t<Iterator>;

        constexpr move_iterator();
        constexpr explicit move_iterator(Iterator i);
        template<class U> constexpr move_iterator(const move_iterator<U>& u);
        template<class U> constexpr move_iterator& operator=(const move_iterator<U>& u);

        constexpr const Iterator& base() const & noexcept;
        constexpr Iterator base() &&;
        constexpr reference operator*() const;

        constexpr move_iterator& operator++();
        constexpr auto operator++(int);
        constexpr move_iterator& operator--();
        constexpr move_iterator& operator--(int);

        constexpr move_iterator& operator+(difference_type n) const;
        constexpr move_iterator& operator+=(difference_type n);
        constexpr move_iterator& operator-(difference_type n) const;
        constexpr move_iterator& operator-=(difference_type n);
        constexpr reference operator[](difference_type n) const;

        template<sentinel_for<Iterator> S>
        friend constexpr bool
            operator==(const move_iterator& x, const move_sentinel<S>& y);
        template<sized_sentinel_for<Iterator> S>
        friend constexpr iter_difference_t<Iterator>
            operator-(const move_sentinel<S>& x, const move_iterator& y);
        template<sized_sentinel_for<Iterator> S>
        friend constexpr iter_difference_t<Iterator>
            operator-(const move_iterator& x, const move_sentinel<S>& y);
        friend constexpr iter_rvalue_reference_t<Iterator>
            iter_move(const move_iterator& i)
            noexcept(noexcept(ranges::iter_move(i.current)));
        template<indirectly_swappable<Iterator> Iterator2>
        friend constexpr void
            iter_swap(const move_iterator& x, const move_iterator<Iterator2>& y)
            noexcept(noexcept(ranges::iter_swap(x.current, y.current)));
    };
}
```

```
private:
    Iterator current;    // exposition only
};
}
```

The member *typedef-name* `iterator_concept` is defined as follows:

- If `Iterator` models `random_access_iterator`, then `iterator_concept` denotes `random_access_iterator_tag`.
- Otherwise, if `Iterator` models `bidirectional_iterator`, then `iterator_concept` denotes `bidirectional_iterator_tag`.
- Otherwise, if `Iterator` models `forward_iterator`, then `iterator_concept` denotes `forward_iterator_tag`.
- Otherwise, `iterator_concept` denotes `input_iterator_tag`.

The member *typedef-name* `iterator_category` is defined if and only if the *qualified-id* `iterator_traits<Iterator>::iterator_category` is valid and denotes a type. In that case, `iterator_category` denotes

- `random_access_iterator_tag` if the type `iterator_traits<Iterator>::iterator_category` models `derived_from<random_access_iterator_tag>`, and
- `iterator_traits<Iterator>::iterator_category` otherwise.

25.5.4.3 Requirements [move.iter.requirements]

The template parameter `Iterator` shall either meet the *Cpp17InputIterator* requirements (25.3.5.3) or model `input_iterator` (25.3.4.9). Additionally, if any of the bidirectional traversal functions are instantiated, the template parameter shall either meet the *Cpp17BidirectionalIterator* requirements (25.3.5.6) or model `bidirectional_iterator` (25.3.4.12). If any of the random access traversal functions are instantiated, the template parameter shall either meet the *Cpp17RandomAccessIterator* requirements (25.3.5.7) or model `random_access_iterator` (25.3.4.13).

25.5.4.4 Construction and assignment [move.iter.cons]

```
constexpr move_iterator();
```

Effects: Value-initializes `current`.

```
constexpr explicit move_iterator(Iterator i);
```

Effects: Initializes `current` with `std::move(i)`.

```
template<class U> constexpr move_iterator(const move_iterator<U>& u);
```

Constraints: `is_same_v<U, Iterator>` is false and `const U&` models `convertible_to<Iterator>`.

Effects: Initializes `current` with `u.current`.

```
template<class U> constexpr move_iterator& operator=(const move_iterator<U>& u);
```

Constraints: `is_same_v<U, Iterator>` is false, `const U&` models `convertible_to<Iterator>`, and `assignable_from<Iterator&, const U&>` is modeled.

Effects: Assigns `u.current` to `current`.

Returns: `*this`.

25.5.4.5 Conversion [move.iter.op.conv]

```
constexpr const Iterator& base() const & noexcept;
```

Returns: `current`.

```
constexpr Iterator base() &&;
```

Returns: `std::move(current)`.

25.5.4.6 Element access [move.iter.elem]

```
constexpr reference operator*() const;
```

Effects: Equivalent to: `return ranges::iter_move(current);`

```
constexpr reference operator[](difference_type n) const;
```

Effects: Equivalent to: `return ranges::iter_move(current + n);`

25.5.4.7 Navigation

[move.iter.nav]

```
constexpr move_iterator& operator++();
```

Effects: As if by `++current`.

Returns: `*this`.

```
constexpr auto operator++(int);
```

Effects: If `Iterator` models `forward_iterator`, equivalent to:

```
move_iterator tmp = *this;
++current;
return tmp;
```

Otherwise, equivalent to `++current`.

```
constexpr move_iterator& operator--();
```

Effects: As if by `--current`.

Returns: `*this`.

```
constexpr move_iterator operator--(int);
```

Effects: As if by:

```
move_iterator tmp = *this;
--current;
return tmp;
```

```
constexpr move_iterator operator+(difference_type n) const;
```

Returns: `move_iterator(current + n)`.

```
constexpr move_iterator& operator+=(difference_type n);
```

Effects: As if by: `current += n;`

Returns: `*this`.

```
constexpr move_iterator operator-(difference_type n) const;
```

Returns: `move_iterator(current - n)`.

```
constexpr move_iterator& operator-=(difference_type n);
```

Effects: As if by: `current -= n;`

Returns: `*this`.

25.5.4.8 Comparisons

[move.iter.op.comp]

```
template<class Iterator1, class Iterator2>
```

```
constexpr bool operator==(const move_iterator<Iterator1>& x,
                          const move_iterator<Iterator2>& y);
```

```
template<sentinel_for<Iterator> S>
```

```
friend constexpr bool operator==(const move_iterator& x,
                                const move_sentinel<S>& y);
```

Constraints: `x.base() == y.base()` is well-formed and convertible to `bool`.

Returns: `x.base() == y.base()`.

```
template<class Iterator1, class Iterator2>
```

```
constexpr bool operator<(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
```

Constraints: `x.base() < y.base()` is well-formed and convertible to `bool`.

Returns: `x.base() < y.base()`.

```
template<class Iterator1, class Iterator2>
constexpr bool operator>(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
```

Constraints: $y.\text{base}() < x.\text{base}()$ is well-formed and convertible to bool.

Returns: $y < x$.

```
template<class Iterator1, class Iterator2>
constexpr bool operator<=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
```

Constraints: $y.\text{base}() < x.\text{base}()$ is well-formed and convertible to bool.

Returns: $!(y < x)$.

```
template<class Iterator1, class Iterator2>
constexpr bool operator>=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
```

Constraints: $x.\text{base}() < y.\text{base}()$ is well-formed and convertible to bool.

Returns: $!(x < y)$.

```
template<class Iterator1, three_way_comparable_with<Iterator1> Iterator2>
constexpr compare_three_way_result_t<Iterator1, Iterator2>
operator<=>(const move_iterator<Iterator1>& x,
           const move_iterator<Iterator2>& y);
```

Returns: $x.\text{base}() <=> y.\text{base}()$.

25.5.4.9 Non-member functions

[move.iter.nonmember]

```
template<class Iterator1, class Iterator2>
constexpr auto operator-(
    const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y)
    -> decltype(x.base() - y.base());
```

```
template< sized_sentinel_for<Iterator> S>
friend constexpr iter_difference_t<Iterator>
operator-(const move_sentinel<S>& x, const move_iterator& y);
template< sized_sentinel_for<Iterator> S>
friend constexpr iter_difference_t<Iterator>
operator-(const move_iterator& x, const move_sentinel<S>& y);
```

Returns: $x.\text{base}() - y.\text{base}()$.

```
template<class Iterator>
constexpr move_iterator<Iterator>
operator+(iter_difference_t<Iterator> n, const move_iterator<Iterator>& x);
```

Constraints: $x.\text{base}() + n$ is well-formed and has type Iterator.

Returns: $x + n$.

```
friend constexpr iter_rvalue_reference_t<Iterator>
iter_move(const move_iterator& i)
    noexcept(noexcept(ranges::iter_move(i.current)));
Effects: Equivalent to: return ranges::iter_move(i.current);
```

```
template<indirectly_swappable<Iterator> Iterator2>
friend constexpr void
iter_swap(const move_iterator& x, const move_iterator<Iterator2>& y)
    noexcept(noexcept(ranges::iter_swap(x.current, y.current)));
Effects: Equivalent to: ranges::iter_swap(x.current, y.current).
```

```
template<class Iterator>
constexpr move_iterator<Iterator> make_move_iterator(Iterator i);
Returns: move_iterator<Iterator>(std::move(i)).
```

25.5.4.10 Class template `move_sentinel`**[move.sentinel]**

Class template `move_sentinel` is a sentinel adaptor useful for denoting ranges together with `move_iterator`. When an input iterator type `I` and sentinel type `S` model `sentinel_for<S, I>`, `move_sentinel<S>` and `move_iterator<I>` model `sentinel_for<move_sentinel<S>, move_iterator<I>>` as well.

EXAMPLE A `move_if` algorithm is easily implemented with `copy_if` using `move_iterator` and `move_sentinel`:

```
template<input_iterator I, sentinel_for<I> S, weakly_incrementable O,
        indirect_unary_predicate<I> Pred>
    requires indirectly_movable<I, O>
void move_if(I first, S last, O out, Pred pred) {
    ranges::copy_if(move_iterator<I>{std::move(first)}, move_sentinel<S>{last},
                   std::move(out), pred);
}

namespace std {
    template<semiregular S>
    class move_sentinel {
    public:
        constexpr move_sentinel();
        constexpr explicit move_sentinel(S s);
        template<class S2>
            requires convertible_to<const S2&, S>
            constexpr move_sentinel(const move_sentinel<S2>& s);
        template<class S2>
            requires assignable_from<S&, const S2&>
            constexpr move_sentinel& operator=(const move_sentinel<S2>& s);

        constexpr S base() const;

    private:
        S last;    // exposition only
    };
}
```

25.5.4.11 Operations**[move.sent.ops]**

```
constexpr move_sentinel();
```

Effects: Value-initializes `last`. If `is_trivially_default_constructible_v<S>` is true, then this constructor is a `constexpr` constructor.

```
constexpr explicit move_sentinel(S s);
```

Effects: Initializes `last` with `std::move(s)`.

```
template<class S2>
    requires convertible_to<const S2&, S>
    constexpr move_sentinel(const move_sentinel<S2>& s);
```

Effects: Initializes `last` with `s.last`.

```
template<class S2>
    requires assignable_from<S&, const S2&>
    constexpr move_sentinel& operator=(const move_sentinel<S2>& s);
```

Effects: Equivalent to: `last = s.last; return *this;`

```
constexpr S base() const;
```

Returns: `last`.

25.5.5 Common iterators**[iterators.common]****25.5.5.1 Class template `common_iterator`****[common.iterator]**

Class template `common_iterator` is an iterator/sentinel adaptor that is capable of representing a non-common range of elements (where the types of the iterator and sentinel differ) as a common range (where they are the same). It does this by holding either an iterator or a sentinel, and implementing the equality comparison operators appropriately.

NOTE The `common_iterator` type is useful for interfacing with legacy code that expects the begin and end of a range to have the same type.

EXAMPLE

```
template<class ForwardIterator>
void fun(ForwardIterator begin, ForwardIterator end);

list<int> s;
// populate the list s
using CI = common_iterator<counted_iterator<list<int>::iterator>, default_sentinel_t>;
// call fun on a range of 10 ints
fun(CI(counted_iterator(s.begin(), 10)), CI(default_sentinel));

namespace std {
    template<input_or_output_iterator I, sentinel_for<I> S>
        requires (!same_as<I, S> && copyable<I>)
        class common_iterator {
        public:
            constexpr common_iterator() requires default_initializable<I> = default;
            constexpr common_iterator(I i);
            constexpr common_iterator(S s);
            template<class I2, class S2>
                requires convertible_to<const I2&, I> && convertible_to<const S2&, S>
                constexpr common_iterator(const common_iterator<I2, S2>& x);

            template<class I2, class S2>
                requires convertible_to<const I2&, I> && convertible_to<const S2&, S> &&
                    assignable_from<I&, const I2&> && assignable_from<S&, const S2&>
                constexpr common_iterator& operator=(const common_iterator<I2, S2>& x);

            constexpr decltype(auto) operator*();
            constexpr decltype(auto) operator*() const
                requires dereferenceable<const I>;
            constexpr auto operator->() const
                requires see below;

            constexpr common_iterator& operator++();
            constexpr decltype(auto) operator++(int);

            template<class I2, sentinel_for<I> S2>
                requires sentinel_for<S, I2>
            friend constexpr bool operator==(
                const common_iterator& x, const common_iterator<I2, S2>& y);
            template<class I2, sentinel_for<I> S2>
                requires sentinel_for<S, I2> && equality_comparable_with<I, I2>
            friend constexpr bool operator==(
                const common_iterator& x, const common_iterator<I2, S2>& y);

            template<sized_sentinel_for<I> I2, sized_sentinel_for<I> S2>
                requires sized_sentinel_for<S, I2>
            friend constexpr iter_difference_t<I2> operator-(
                const common_iterator& x, const common_iterator<I2, S2>& y);

            friend constexpr iter_rvalue_reference_t<I> iter_move(const common_iterator& i)
                noexcept(noexcept(ranges::iter_move(declval<const I&>()))
                requires input_iterator<I>;
            template<indirectly_swappable<I> I2, class S2>
                friend constexpr void iter_swap(const common_iterator& x, const common_iterator<I2, S2>& y)
                noexcept(noexcept(ranges::iter_swap(declval<const I&>(), declval<const I2&>())));

        private:
            variant<I, S> v_; // exposition only
    };
```

```

template<class I, class S>
struct incrementable_traits<common_iterator<I, S>> {
    using difference_type = iter_difference_t<I>;
};

template<input_iterator I, class S>
struct iterator_traits<common_iterator<I, S>> {
    using iterator_concept = see below;
    using iterator_category = see below;
    using value_type = iter_value_t<I>;
    using difference_type = iter_difference_t<I>;
    using pointer = see below;
    using reference = iter_reference_t<I>;
};
}

```

25.5.5.2 Associated types

[common.iter.types]

The nested *typedef-names* of the specialization of `iterator_traits` for `common_iterator<I, S>` are defined as follows.

- `iterator_concept` denotes `forward_iterator_tag` if `I` models `forward_iterator`; otherwise it denotes `input_iterator_tag`.
- `iterator_category` denotes `forward_iterator_tag` if the *qualified-id* `iterator_traits<I>::iterator_category` is valid and denotes a type that models `derived_from<forward_iterator_tag>`; otherwise it denotes `input_iterator_tag`.
- Let `a` denote an lvalue of type `const common_iterator<I, S>`. If the expression `a.operator->()` is well-formed, then `pointer` denotes `decltype(a.operator->())`. Otherwise, `pointer` denotes `void`.

25.5.5.3 Constructors and conversions

[common.iter.const]

```
constexpr common_iterator(I i);
```

Effects: Initializes `v_` as if by `v_{in_place_type<I>, std::move(i)}`.

```
constexpr common_iterator(S s);
```

Effects: Initializes `v_` as if by `v_{in_place_type<S>, std::move(s)}`.

```
template<class I2, class S2>
```

```
requires convertible_to<const I2&, I> && convertible_to<const S2&, S>
constexpr common_iterator(const common_iterator<I2, S2>& x);
```

Preconditions: `x.v_.valueless_by_exception()` is false.

Effects: Initializes `v_` as if by `v_{in_place_index<i>, get<i>(x.v_)}`, where `i` is `x.v_.index()`.

```
template<class I2, class S2>
```

```
requires convertible_to<const I2&, I> && convertible_to<const S2&, S> &&
    assignable_from<I&, const I2&> && assignable_from<S&, const S2&>
constexpr common_iterator& operator=(const common_iterator<I2, S2>& x);
```

Preconditions: `x.v_.valueless_by_exception()` is false.

Effects: Equivalent to:

- If `v_.index() == x.v_.index()`, then `get<i>(v_) = get<i>(x.v_)`.
- Otherwise, `v_.emplace<i>(get<i>(x.v_))`.

where `i` is `x.v_.index()`.

Returns: `*this`

25.5.5.4 Accessors

[common.iter.access]

```
constexpr decltype(auto) operator*();
constexpr decltype(auto) operator*() const
requires dereferenceable<const I>;
```

Preconditions: `holds_alternative<I>(v_)` is true.

Effects: Equivalent to: `return *get<I>(v_);`

`constexpr auto operator->() const`
requires *see below*;

The expression in the *requires-clause* is equivalent to:

```
indirectly_readable<const I> &&
(requires(const I& i) { i.operator->(); } ||
 is_reference_v<iter_reference_t<I>> ||
 constructible_from<iter_value_t<I>, iter_reference_t<I>>)
```

Preconditions: `holds_alternative<I>(v_)` is true.

Effects:

- If `I` is a pointer type or if the expression `get<I>(v_).operator->()` is well-formed, equivalent to: `return get<I>(v_);`
- Otherwise, if `iter_reference_t<I>` is a reference type, equivalent to:

```
auto&& tmp = *get<I>(v_);
return addressof(tmp);
```
- Otherwise, equivalent to: `return proxy(*get<I>(v_));` where *proxy* is the exposition-only class:

```
class proxy {
    iter_value_t<I> keep_;
    constexpr proxy(iter_reference_t<I>&& x)
        : keep_(std::move(x)) {}
public:
    constexpr const iter_value_t<I>* operator->() const noexcept {
        return addressof(keep_);
    }
};
```

25.5.5.5 Navigation

[common.iter.nav]

`constexpr common_iterator& operator++();`

Preconditions: `holds_alternative<I>(v_)` is true.

Effects: Equivalent to `++get<I>(v_)`.

Returns: `*this`.

`constexpr decltype(auto) operator++(int);`

Preconditions: `holds_alternative<I>(v_)` is true.

Effects: If `I` models `forward_iterator`, equivalent to:

```
common_iterator tmp = *this;
++*this;
return tmp;
```

Otherwise, if `requires(I& i) { { *i++ } -> can-reference; }` is true or

```
indirectly_readable<I> && constructible_from<iter_value_t<I>, iter_reference_t<I>> &&
move_constructible<iter_value_t<I>>
```

is false, equivalent to:

```
return get<I>(v_++);
```

Otherwise, equivalent to:

```
postfix-proxy p(**this);
++*this;
return p;
```

where *postfix-proxy* is the exposition-only class:

```
class postfix-proxy {
    iter_value_t<I> keep_;
```

```
constexpr postfix-proxy(iter_reference_t<I>&& x)
: keep_(std::forward<iter_reference_t<I>>(x)) {}
public:
constexpr const iter_value_t<I>& operator*() const noexcept {
return keep_;
}
};
```

25.5.5.6 Comparisons

[common.iter.cmp]

```
template<class I2, sentinel_for<I> S2>
requires sentinel_for<S, I2>
friend constexpr bool operator==(
const common_iterator& x, const common_iterator<I2, S2>& y);
```

Preconditions: `x.v_.valueless_by_exception()` and `y.v_.valueless_by_exception()` are each false.

Returns: true if $i == j$, and otherwise `get<i>(x.v_) == get<j>(y.v_)`, where i is `x.v_.index()` and j is `y.v_.index()`.

```
template<class I2, sentinel_for<I> S2>
requires sentinel_for<S, I2> && equality_comparable_with<I, I2>
friend constexpr bool operator==(
const common_iterator& x, const common_iterator<I2, S2>& y);
```

Preconditions: `x.v_.valueless_by_exception()` and `y.v_.valueless_by_exception()` are each false.

Returns: true if i and j are each 1, and otherwise `get<i>(x.v_) == get<j>(y.v_)`, where i is `x.v_.index()` and j is `y.v_.index()`.

```
template<sized_sentinel_for<I> I2, sized_sentinel_for<I> S2>
requires sized_sentinel_for<S, I2>
friend constexpr iter_difference_t<I2> operator-(
const common_iterator& x, const common_iterator<I2, S2>& y);
```

Preconditions: `x.v_.valueless_by_exception()` and `y.v_.valueless_by_exception()` are each false.

Returns: 0 if i and j are each 1, and otherwise `get<i>(x.v_) - get<j>(y.v_)`, where i is `x.v_.index()` and j is `y.v_.index()`.

25.5.5.7 Customizations

[common.iter.cust]

```
friend constexpr iter_rvalue_reference_t<I> iter_move(const common_iterator& i)
noexcept(noexcept(ranges::iter_move(declval<const I>&())))
requires input_iterator<I>;
```

Preconditions: `holds_alternative<I>(i.v_)` is true.

Effects: Equivalent to: `return ranges::iter_move(get<I>(i.v_));`

```
template<indirectly_swappable<I> I2, class S2>
friend constexpr void iter_swap(const common_iterator& x, const common_iterator<I2, S2>& y)
noexcept(noexcept(ranges::iter_swap(declval<const I>&(), declval<const I2>&())));
```

Preconditions: `holds_alternative<I>(x.v_)` and `holds_alternative<I2>(y.v_)` are each true.

Effects: Equivalent to `ranges::iter_swap(get<I>(x.v_), get<I2>(y.v_))`.

25.5.6 Default sentinel

[default.sentinel]

```
namespace std {
struct default_sentinel_t { };
}
```

Class `default_sentinel_t` is an empty type used to denote the end of a range. It can be used together with iterator types that know the bound of their range (e.g., `counted_iterator` (25.5.7.1)).

25.5.7 Counted iterators

[iterators.counted]

25.5.7.1 Class template counted_iterator

[counted.iterator]

Class template `counted_iterator` is an iterator adaptor with the same behavior as the underlying iterator except that it keeps track of the distance to the end of its range. It can be used together with `default_sentinel` in calls to generic algorithms to operate on a range of N elements starting at a given position without needing to know the end position a priori.

EXAMPLE

```
list<string> s;
// populate the list s with at least 10 strings
vector<string> v;
// copies 10 strings into v:
ranges::copy(counted_iterator(s.begin(), 10), default_sentinel, back_inserter(v));
```

Two values `i1` and `i2` of types `counted_iterator<I1>` and `counted_iterator<I2>` refer to elements of the same sequence if and only if there exists some integer n such that `next(i1.base(), i1.count() + n)` and `next(i2.base(), i2.count() + n)` refer to the same (possibly past-the-end) element.

```
namespace std {
    template<input_or_output_iterator I>
    class counted_iterator {
    public:
        using iterator_type = I;
        using value_type = iter_value_t<I>; // present only
        // if I models indirectly_readable
        using difference_type = iter_difference_t<I>;
        using iterator_concept = typename I::iterator_concept; // present only
        // if the qualified-id I::iterator_concept is valid and denotes a type
        using iterator_category = typename I::iterator_category; // present only
        // if the qualified-id I::iterator_category is valid and denotes a type
        constexpr counted_iterator() requires default_initializable<I> = default;
        constexpr counted_iterator(I x, iter_difference_t<I> n);
        template<class I2>
            requires convertible_to<const I2&, I>
            constexpr counted_iterator(const counted_iterator<I2>& x);

        template<class I2>
            requires assignable_from<I&, const I2&>
            constexpr counted_iterator& operator=(const counted_iterator<I2>& x);

        constexpr const I& base() const & noexcept;
        constexpr I base() &&;
        constexpr iter_difference_t<I> count() const noexcept;
        constexpr decltype(auto) operator*();
        constexpr decltype(auto) operator*() const
            requires dereferenceable<const I>;

        constexpr auto operator->() const noexcept
            requires contiguous_iterator<I>;

        constexpr counted_iterator& operator++();
        constexpr decltype(auto) operator++(int);
        constexpr counted_iterator operator++(int)
            requires forward_iterator<I>;
        constexpr counted_iterator& operator--();
        constexpr decltype(auto) operator--(int)
            requires bidirectional_iterator<I>;
        constexpr counted_iterator operator--(int)
            requires bidirectional_iterator<I>;

        constexpr counted_iterator operator+(iter_difference_t<I> n) const
            requires random_access_iterator<I>;
        friend constexpr counted_iterator operator+(
            iter_difference_t<I> n, const counted_iterator& x)
            requires random_access_iterator<I>;
```

```

constexpr counted_iterator& operator+=(iter_difference_t<I> n)
    requires random_access_iterator<I>;

constexpr counted_iterator operator-(iter_difference_t<I> n) const
    requires random_access_iterator<I>;
template<common_with<I> I2>
    friend constexpr iter_difference_t<I2> operator-(
        const counted_iterator& x, const counted_iterator<I2>& y);
friend constexpr iter_difference_t<I> operator-(
    const counted_iterator& x, default_sentinel_t);
friend constexpr iter_difference_t<I> operator-(
    default_sentinel_t, const counted_iterator& y);
constexpr counted_iterator& operator-=(iter_difference_t<I> n)
    requires random_access_iterator<I>;

constexpr decltype(auto) operator[](iter_difference_t<I> n) const
    requires random_access_iterator<I>;

template<common_with<I> I2>
    friend constexpr bool operator==(
        const counted_iterator& x, const counted_iterator<I2>& y);
friend constexpr bool operator==(
    const counted_iterator& x, default_sentinel_t);

template<common_with<I> I2>
    friend constexpr strong_ordering operator<=(
        const counted_iterator& x, const counted_iterator<I2>& y);

friend constexpr iter_rvalue_reference_t<I> iter_move(const counted_iterator& i)
    noexcept(noexcept(ranges::iter_move(i.current)))
    requires input_iterator<I>;
template<indirectly_swappable<I> I2>
    friend constexpr void iter_swap(const counted_iterator& x, const counted_iterator<I2>& y)
        noexcept(noexcept(ranges::iter_swap(x.current, y.current)));

private:
    I current = I(); // exposition only
    iter_difference_t<I> length = 0; // exposition only
};

template<input_iterator I>
    requires same_as<ITER_TRAITS(I), iterator_traits<I>> // see 25.3.4.1
struct iterator_traits<counted_iterator<I>> : iterator_traits<I> {
    using pointer = conditional_t<contiguous_iterator<I>,
        add_pointer_t<iter_reference_t<I>>, void>;
};
}

```

25.5.7.2 Constructors and conversions

[counted.iter.const]

```
constexpr counted_iterator(I i, iter_difference_t<I> n);
```

Preconditions: $n \geq 0$.

Effects: Initializes current with `std::move(i)` and length with `n`.

```
template<class I2>
    requires convertible_to<const I2&, I>
constexpr counted_iterator(const counted_iterator<I2>& x);
```

Effects: Initializes current with `x.current` and length with `x.length`.

```
template<class I2>
    requires assignable_from<I&, const I2&>
constexpr counted_iterator& operator=(const counted_iterator<I2>& x);
```

Effects: Assigns `x.current` to current and `x.length` to length.

Returns: `*this`.

25.5.7.3 Accessors

[counted.iter.access]

```
constexpr const I& base() const & noexcept;
```

Effects: Equivalent to: `return current`;

```
constexpr I base() &&;
```

Returns: `std::move(current)`.

```
constexpr iter_difference_t<I> count() const noexcept;
```

Effects: Equivalent to: `return length`;

25.5.7.4 Element access

[counted.iter.elem]

```
constexpr decltype(auto) operator*();
```

```
constexpr decltype(auto) operator*() const
```

```
requires dereferenceable<const I>;
```

Preconditions: `length > 0` is true.

Effects: Equivalent to: `return *current`;

```
constexpr auto operator->() const noexcept
```

```
requires contiguous_iterator<I>;
```

Effects: Equivalent to: `return to_address(current)`;

```
constexpr decltype(auto) operator[](iter_difference_t<I> n) const
```

```
requires random_access_iterator<I>;
```

Preconditions: `n < length`.

Effects: Equivalent to: `return current[n]`;

25.5.7.5 Navigation

[counted.iter.nav]

```
constexpr counted_iterator& operator++();
```

Preconditions: `length > 0`.

Effects: Equivalent to:

```
++current;
--length;
return *this;
```

```
constexpr decltype(auto) operator++(int);
```

Preconditions: `length > 0`.

Effects: Equivalent to:

```
--length;
try { return current++; }
catch(...) { ++length; throw; }
```

```
constexpr counted_iterator operator++(int)
```

```
requires forward_iterator<I>;
```

Effects: Equivalent to:

```
counted_iterator tmp = *this;
+++this;
return tmp;
```

```
constexpr counted_iterator& operator--()
```

```
requires bidirectional_iterator<I>;
```

Effects: Equivalent to:

```
--current;
++length;
```

```

    return *this;

constexpr counted_iterator operator--(int)
    requires bidirectional_iterator<I>;

    Effects: Equivalent to:

        counted_iterator tmp = *this;
        --*this;
        return tmp;

constexpr counted_iterator operator+(iter_difference_t<I> n) const
    requires random_access_iterator<I>;

    Effects: Equivalent to: return counted_iterator(current + n, length - n);

friend constexpr counted_iterator operator+(
    iter_difference_t<I> n, const counted_iterator& x)
    requires random_access_iterator<I>;

    Effects: Equivalent to: return x + n;

constexpr counted_iterator& operator+=(iter_difference_t<I> n)
    requires random_access_iterator<I>;

    Preconditions: n <= length.
    Effects: Equivalent to:

        current += n;
        length -= n;
        return *this;

constexpr counted_iterator operator-(iter_difference_t<I> n) const
    requires random_access_iterator<I>;

    Effects: Equivalent to: return counted_iterator(current - n, length + n);

template<common_with<I> I2>
    friend constexpr iter_difference_t<I2> operator-(
        const counted_iterator& x, const counted_iterator<I2>& y);

    Preconditions: x and y refer to elements of the same sequence (25.5.7.1).
    Effects: Equivalent to: return y.length - x.length;

friend constexpr iter_difference_t<I> operator-(
    const counted_iterator& x, default_sentinel_t);

    Effects: Equivalent to: return -x.length;

friend constexpr iter_difference_t<I> operator-(
    default_sentinel_t, const counted_iterator& y);

    Effects: Equivalent to: return y.length;

constexpr counted_iterator& operator-=(iter_difference_t<I> n)
    requires random_access_iterator<I>;

    Preconditions: -n <= length.
    Effects: Equivalent to:

        current -= n;
        length += n;
        return *this;

```

25.5.7.6 Comparisons

[counted.iter.cmp]

```

template<common_with<I> I2>
    friend constexpr bool operator==(
        const counted_iterator& x, const counted_iterator<I2>& y);

    Preconditions: x and y refer to elements of the same sequence (25.5.7.1).

```

Effects: Equivalent to: `return x.length == y.length;`

```
friend constexpr bool operator==(
    const counted_iterator& x, default_sentinel_t);
```

Effects: Equivalent to: `return x.length == 0;`

```
template<common_with<I> I2>
    friend constexpr strong_ordering operator<=(
        const counted_iterator& x, const counted_iterator<I2>& y);
```

Preconditions: `x` and `y` refer to elements of the same sequence (25.5.7.1).

Effects: Equivalent to: `return y.length <= x.length;`

NOTE The argument order in the *Effects:* element is reversed because `length` counts down, not up.

25.5.7.7 Customizations

[counted.iter.cust]

```
friend constexpr iter_rvalue_reference_t<I>
    iter_move(const counted_iterator& i)
    noexcept(noexcept(ranges::iter_move(i.current)))
    requires input_iterator<I>;
```

Preconditions: `i.length > 0` is true.

Effects: Equivalent to: `return ranges::iter_move(i.current);`

```
template<indirectly_swappable<I> I2>
    friend constexpr void
        iter_swap(const counted_iterator& x, const counted_iterator<I2>& y)
        noexcept(noexcept(ranges::iter_swap(x.current, y.current)));
```

Preconditions: Both `x.length > 0` and `y.length > 0` are true.

Effects: Equivalent to `ranges::iter_swap(x.current, y.current)`.

25.5.8 Unreachable sentinel

[unreachable.sentinel]

Class `unreachable_sentinel_t` can be used with any `weakly_incrementable` type to denote the “upper bound” of an unbounded interval.

EXAMPLE

```
char* p;
// set p to point to a character buffer containing newlines
char* nl = find(p, unreachable_sentinel, '\n');
```

Provided a newline character really exists in the buffer, the use of `unreachable_sentinel` above potentially makes the call to `find` more efficient since the loop test against the sentinel does not require a conditional branch.

```
namespace std {
    struct unreachable_sentinel_t {
        template<weakly_incrementable I>
            friend constexpr bool operator==(unreachable_sentinel_t, const I&) noexcept
            { return false; }
    };
}
```

25.6 Stream iterators

[stream.iterators]

25.6.1 General

[stream.iterators.general]

To make it possible for algorithmic templates to work directly with input/output streams, appropriate iterator-like class templates are provided.

EXAMPLE

```
partial_sum(istream_iterator<double, char>(cin),
    istream_iterator<double, char>(),
    ostream_iterator<double, char>(cout, "\n"));
```

reads a file containing floating-point numbers from `cin`, and prints the partial sums onto `cout`.

25.6.2 Class template `istream_iterator`**[istream.iterator]****25.6.2.1 General****[istream.iterator.general]**

The class template `istream_iterator` is an input iterator (25.3.5.3) that reads successive elements from the input stream for which it was constructed.

```
namespace std {
    template<class T, class charT = char, class traits = char_traits<charT>,
            class Distance = ptrdiff_t>
    class istream_iterator {
    public:
        using iterator_category = input_iterator_tag;
        using value_type        = T;
        using difference_type    = Distance;
        using pointer            = const T*;
        using reference          = const T&;
        using char_type          = charT;
        using traits_type        = traits;
        using istream_type       = basic_istream<charT, traits>;

        constexpr istream_iterator();
        constexpr istream_iterator(default_sentinel_t);
        istream_iterator(istream_type& s);
        constexpr istream_iterator(const istream_iterator& x) noexcept(see below);
        ~istream_iterator() = default;
        istream_iterator& operator=(const istream_iterator&) = default;

        const T& operator*() const;
        const T* operator->() const;
        istream_iterator& operator++();
        istream_iterator operator++(int);

        friend bool operator==(const istream_iterator& i, default_sentinel_t);

    private:
        basic_istream<charT, traits>* in_stream; // exposition only
        T value;                                // exposition only
    };
}
```

The type `T` shall meet the *Cpp17DefaultConstructible*, *Cpp17CopyConstructible*, and *Cpp17CopyAssignable* requirements.

25.6.2.2 Constructors and destructor**[istream.iterator.cons]**

```
constexpr istream_iterator();
constexpr istream_iterator(default_sentinel_t);
```

Effects: Constructs the end-of-stream iterator, value-initializing `value`.

Postconditions: `in_stream == nullptr` is true.

Remarks: If the initializer `T()` in the declaration `auto x = T();` is a constant initializer (7.7), then these constructors are `constexpr` constructors.

```
istream_iterator(istream_type& s);
```

Effects: Initializes `in_stream` with `addressof(s)`, value-initializes `value`, and then calls `operator++()`.

```
constexpr istream_iterator(const istream_iterator& x) noexcept(see below);
```

Effects: Initializes `in_stream` with `x.in_stream` and initializes `value` with `x.value`.

Remarks: An invocation of this constructor may be used in a core constant expression if and only if the initialization of `value` from `x.value` is a constant subexpression (3.14). The exception specification is equivalent to `is_nothrow_copy_constructible_v<T>`.

```
~istream_iterator() = default;
```

Remarks: If `is_trivially_destructible_v<T>` is true, then this destructor is trivial.

25.6.2.3 Operations

[istream.iterator.ops]

```
const T& operator*() const;
```

Preconditions: in_stream != nullptr is true.

Returns: value.

```
const T* operator->() const;
```

Preconditions: in_stream != nullptr is true.

Returns: addressof(value).

```
istream_iterator& operator++();
```

Preconditions: in_stream != nullptr is true.

Effects: Equivalent to:

```
if (!(*in_stream >> value))
    in_stream = nullptr;
```

Returns: *this.

```
istream_iterator operator++(int);
```

Preconditions: in_stream != nullptr is true.

Effects: Equivalent to:

```
istream_iterator tmp = *this;
++*this;
return tmp;
```

```
template<class T, class charT, class traits, class Distance>
```

```
bool operator==(const istream_iterator<T,charT,traits,Distance>& x,
                const istream_iterator<T,charT,traits,Distance>& y);
```

Returns: x.in_stream == y.in_stream.

```
friend bool operator==(const istream_iterator& i, default_sentinel_t);
```

Returns: !i.in_stream.

25.6.3 Class template ostream_iterator

[ostream.iterator]

25.6.3.1 General

[ostream.iterator.general]

ostream_iterator writes (using operator<<) successive elements onto the output stream from which it was constructed. If it was constructed with charT* as a constructor argument, this string, called a *delimiter string*, is written to the stream after every T is written.

```
namespace std {
    template<class T, class charT = char, class traits = char_traits<charT>>
    class ostream_iterator {
    public:
        using iterator_category = output_iterator_tag;
        using value_type = void;
        using difference_type = ptrdiff_t;
        using pointer = void;
        using reference = void;
        using char_type = charT;
        using traits_type = traits;
        using ostream_type = basic_ostream<charT,traits>;

        ostream_iterator(ostream_type& s);
        ostream_iterator(ostream_type& s, const charT* delimiter);
        ostream_iterator(const ostream_iterator& x);
        ~ostream_iterator();
        ostream_iterator& operator=(const ostream_iterator&) = default;
        ostream_iterator& operator=(const T& value);
    };
}
```

```

ostream_iterator& operator*();
ostream_iterator& operator++();
ostream_iterator& operator++(int);

private:
    basic_ostream<charT,traits>* out_stream;           // exposition only
    const charT* delim;                               // exposition only
};
}

```

25.6.3.2 Constructors and destructor

[ostream.iterator.cons.des]

```
ostream_iterator(ostream_type& s);
```

Effects: Initializes `out_stream` with `addressof(s)` and `delim` with `nullptr`.

```
ostream_iterator(ostream_type& s, const charT* delimiter);
```

Effects: Initializes `out_stream` with `addressof(s)` and `delim` with `delimiter`.

25.6.3.3 Operations

[ostream.iterator.ops]

```
ostream_iterator& operator=(const T& value);
```

Effects: As if by:

```

*out_stream << value;
if (delim)
    *out_stream << delim;
return *this;

```

```
ostream_iterator& operator*();
```

Returns: `*this`.

```
ostream_iterator& operator++();
```

```
ostream_iterator& operator++(int);
```

Returns: `*this`.

25.6.4 Class template `istreambuf_iterator`

[istreambuf.iterator]

25.6.4.1 General

[istreambuf.iterator.general]

The class template `istreambuf_iterator` defines an input iterator (25.3.5.3) that reads successive *characters* from the streambuf for which it was constructed. `operator*` provides access to the current input character, if any. Each time `operator++` is evaluated, the iterator advances to the next input character. If the end of stream is reached (`streambuf_type::sgetc()` returns `traits::eof()`), the iterator becomes equal to the *end-of-stream* iterator value. The default constructor `istreambuf_iterator()` and the constructor `istreambuf_iterator(nullptr)` both construct an end-of-stream iterator object suitable for use as an end-of-range. All specializations of `istreambuf_iterator` shall have a trivial copy constructor, a `constexpr` default constructor, and a trivial destructor.

The result of `operator*()` on an end-of-stream iterator is undefined. For any other iterator value a `char_type` value is returned. It is impossible to assign a character via an input iterator.

```

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class istreambuf_iterator {
    public:
        using iterator_category = input_iterator_tag;
        using value_type        = charT;
        using difference_type    = typename traits::off_type;
        using pointer            = unspecified;
        using reference          = charT;
        using char_type          = charT;
        using traits_type        = traits;
        using int_type           = typename traits::int_type;
        using streambuf_type     = basic_streambuf<charT,traits>;
        using istream_type       = basic_istream<charT,traits>;

```

```

// 25.6.4.2, class istreambuf_iterator::proxy
class proxy; // exposition only

constexpr istreambuf_iterator() noexcept;
constexpr istreambuf_iterator(default_sentinel_t) noexcept;
istreambuf_iterator(const istreambuf_iterator&) noexcept = default;
~istreambuf_iterator() = default;
istreambuf_iterator(istream_type& s) noexcept;
istreambuf_iterator(streambuf_type* s) noexcept;
istreambuf_iterator(const proxy& p) noexcept;
istreambuf_iterator& operator=(const istreambuf_iterator&) noexcept = default;
charT operator*() const;
istreambuf_iterator& operator++();
proxy operator++(int);
bool equal(const istreambuf_iterator& b) const;

friend bool operator==(const istreambuf_iterator& i, default_sentinel_t s);

private:
    streambuf_type* sbuf_; // exposition only
};

```

25.6.4.2 Class `istreambuf_iterator::proxy`

[istreambuf.iterator.proxy]

Class `istreambuf_iterator<charT, traits>::proxy` is for exposition only. An implementation is permitted to provide equivalent functionality without providing a class with this name. Class `istreambuf_iterator<charT, traits>::proxy` provides a temporary placeholder as the return value of the post-increment operator (`operator++`). It keeps the character pointed to by the previous value of the iterator for some possible future access to get the character.

```

namespace std {
    template<class charT, class traits>
    class istreambuf_iterator<charT, traits>::proxy { // exposition only
        charT keep_;
        basic_streambuf<charT, traits>* sbuf_;
        proxy(charT c, basic_streambuf<charT, traits>* sbuf)
            : keep_(c), sbuf_(sbuf) { }
    public:
        charT operator*() { return keep_; }
    };
}

```

25.6.4.3 Constructors

[istreambuf.iterator.cons]

For each `istreambuf_iterator` constructor in this subclause, an end-of-stream iterator is constructed if and only if the exposition-only member `sbuf_` is initialized with a null pointer value.

```

constexpr istreambuf_iterator() noexcept;
constexpr istreambuf_iterator(default_sentinel_t) noexcept;

```

Effects: Initializes `sbuf_` with `nullptr`.

```
istreambuf_iterator(istream_type& s) noexcept;
```

Effects: Initializes `sbuf_` with `s.rdbuf()`.

```
istreambuf_iterator(streambuf_type* s) noexcept;
```

Effects: Initializes `sbuf_` with `s`.

```
istreambuf_iterator(const proxy& p) noexcept;
```

Effects: Initializes `sbuf_` with `p.sbuf_`.

25.6.4.4 Operations

[istreambuf.iterator.ops]

```
charT operator*() const;
```

Returns: The character obtained via the `streambuf` member `sbuf_>sgetc()`.

```
istreambuf_iterator& operator++();
```

Effects: As if by `sbuf_->sbumpc()`.

Returns: `*this`.

```
proxy operator++(int);
```

Returns: `proxy(sbuf_->sbumpc(), sbuf_)`.

```
bool equal(const istreambuf_iterator& b) const;
```

Returns: `true` if and only if both iterators are at end-of-stream, or neither is at end-of-stream, regardless of what `streambuf` object they use.

```
template<class charT, class traits>
```

```
bool operator==(const istreambuf_iterator<charT,traits>& a,  
                const istreambuf_iterator<charT,traits>& b);
```

Returns: `a.equal(b)`.

```
friend bool operator==(const istreambuf_iterator& i, default_sentinel_t s);
```

Returns: `i.equal(s)`.

25.6.5 Class template `ostreambuf_iterator`

[`ostreambuf.iterator`]

25.6.5.1 General

[`ostreambuf.iterator.general`]

The class template `ostreambuf_iterator` writes successive *characters* onto the output stream from which it was constructed.

```
namespace std {  
    template<class charT, class traits = char_traits<charT>>  
    class ostreambuf_iterator {  
    public:  
        using iterator_category = output_iterator_tag;  
        using value_type        = void;  
        using difference_type    = ptrdiff_t;  
        using pointer            = void;  
        using reference          = void;  
        using char_type          = charT;  
        using traits_type        = traits;  
        using streambuf_type     = basic_streambuf<charT,traits>;  
        using ostream_type      = basic_ostream<charT,traits>;  
  
        ostreambuf_iterator(ostream_type& s) noexcept;  
        ostreambuf_iterator(streambuf_type* s) noexcept;  
        ostreambuf_iterator& operator=(charT c);  
  
        ostreambuf_iterator& operator*();  
        ostreambuf_iterator& operator++();  
        ostreambuf_iterator& operator++(int);  
        bool failed() const noexcept;  
  
    private:  
        streambuf_type* sbuf_;           // exposition only  
    };  
}
```

25.6.5.2 Constructors

[`ostreambuf.iter.cons`]

```
ostreambuf_iterator(ostream_type& s) noexcept;
```

Preconditions: `s.rdbuf()` is not a null pointer.

Effects: Initializes `sbuf_` with `s.rdbuf()`.

```
ostreambuf_iterator(streambuf_type* s) noexcept;
```

Preconditions: `s` is not a null pointer.

Effects: Initializes `sbuf_` with `s`.

25.6.5.3 Operations

[ostreambuf.iter.ops]

```
ostreambuf_iterator& operator=(charT c);
```

Effects: If `failed()` yields `false`, calls `sbuf_>sputc(c)`; otherwise has no effect.

Returns: `*this`.

```
ostreambuf_iterator& operator*();
```

Returns: `*this`.

```
ostreambuf_iterator& operator++();
```

```
ostreambuf_iterator& operator++(int);
```

Returns: `*this`.

```
bool failed() const noexcept;
```

Returns: `true` if in any prior use of member `operator=`, the call to `sbuf_>sputc()` returned `traits::eof()`; or `false` otherwise.

25.7 Range access

[iterator.range]

In addition to being available via inclusion of the `<iterator>` header, the function templates in 25.7 are available when any of the following headers are included: `<array>` (24.3.2), `<deque>` (24.3.3), `<forward_list>` (24.3.4), `<list>` (24.3.5), `<map>` (24.4.2), `<regex>` (32.3), `<set>` (24.4.3), `<span>` (24.7.2.1), `<string>` (23.4.2), `<string_view>` (23.3.2), `<unordered_map>` (24.5.2), `<unordered_set>` (24.5.3), and `<vector>` (24.3.6).

```
template<class C> constexpr auto begin(C& c) -> decltype(c.begin());
```

```
template<class C> constexpr auto begin(const C& c) -> decltype(c.begin());
```

Returns: `c.begin()`.

```
template<class C> constexpr auto end(C& c) -> decltype(c.end());
```

```
template<class C> constexpr auto end(const C& c) -> decltype(c.end());
```

Returns: `c.end()`.

```
template<class T, size_t N> constexpr T* begin(T (&array)[N]) noexcept;
```

Returns: `array`.

```
template<class T, size_t N> constexpr T* end(T (&array)[N]) noexcept;
```

Returns: `array + N`.

```
template<class C> constexpr auto cbegin(const C& c) noexcept(noexcept(std::begin(c)))
```

```
-> decltype(std::begin(c));
```

Returns: `std::begin(c)`.

```
template<class C> constexpr auto cend(const C& c) noexcept(noexcept(std::end(c)))
```

```
-> decltype(std::end(c));
```

Returns: `std::end(c)`.

```
template<class C> constexpr auto rbegin(C& c) -> decltype(c.rbegin());
```

```
template<class C> constexpr auto rbegin(const C& c) -> decltype(c.rbegin());
```

Returns: `c.rbegin()`.

```
template<class C> constexpr auto rend(C& c) -> decltype(c.rend());
```

```
template<class C> constexpr auto rend(const C& c) -> decltype(c.rend());
```

Returns: `c.rend()`.

```
template<class T, size_t N> constexpr reverse_iterator<T*> rbegin(T (&array)[N]);
```

Returns: `reverse_iterator<T*>(array + N)`.

template<class T, size_t N> constexpr reverse_iterator<T*> rend(T (&array)[N]);
Returns: reverse_iterator<T*>(array).

template<class E> constexpr reverse_iterator<const E*> rbegin(initializer_list<E> il);
Returns: reverse_iterator<const E*>(il.end()).

template<class E> constexpr reverse_iterator<const E*> rend(initializer_list<E> il);
Returns: reverse_iterator<const E*>(il.begin()).

template<class C> constexpr auto crbegin(const C& c) -> decltype(std::rbegin(c));
Returns: std::rbegin(c).

template<class C> constexpr auto crend(const C& c) -> decltype(std::rend(c));
Returns: std::rend(c).

template<class C> constexpr auto size(const C& c) -> decltype(c.size());
Returns: c.size().

template<class T, size_t N> constexpr size_t size(const T (&array)[N]) noexcept;
Returns: N.

template<class C> constexpr auto ssize(const C& c)
-> common_type_t<ptrdiff_t, make_signed_t<decltype(c.size())>>;
Effects: Equivalent to:
return static_cast<common_type_t<ptrdiff_t, make_signed_t<decltype(c.size())>>>(c.size());

template<class T, ptrdiff_t N> constexpr ptrdiff_t ssize(const T (&array)[N]) noexcept;
Returns: N.

template<class C> [[nodiscard]] constexpr auto empty(const C& c) -> decltype(c.empty());
Returns: c.empty().

template<class T, size_t N> [[nodiscard]] constexpr bool empty(const T (&array)[N]) noexcept;
Returns: false.

template<class E> [[nodiscard]] constexpr bool empty(initializer_list<E> il) noexcept;
Returns: il.size() == 0.

template<class C> constexpr auto data(C& c) -> decltype(c.data());
template<class C> constexpr auto data(const C& c) -> decltype(c.data());
Returns: c.data().

template<class T, size_t N> constexpr T* data(T (&array)[N]) noexcept;
Returns: array.

template<class E> constexpr const E* data(initializer_list<E> il) noexcept;
Returns: il.begin().

26 Ranges library

[ranges]

26.1 General

[ranges.general]

This Clause describes components for dealing with ranges of elements.

The following subclauses describe range and view requirements, and components for range primitives and range generators as summarized in Table 92.

Table 92 — Ranges library summary [tab:range.summary]

	Subclause	Header
26.3	Range access	<ranges>
26.4	Requirements	
26.5	Range utilities	
26.6	Range factories	
26.7	Range adaptors	
26.8	Range generators	<generator>

26.2 Header <ranges> synopsis

[ranges.syn]

```

#include <compare>           // see 17.11.1
#include <initializer_list>   // see 17.10.2
#include <iterator>           // see 25.2

namespace std::ranges {

    inline constexpr from_range_t from_range{}; // freestanding
}

```

Within this Clause, for an integer-like type *X* (25.3.4.4), *make-unsigned-like-t<X>* denotes *make_unsigned_t<X>* if *X* is an integer type; otherwise, it denotes a corresponding unspecified unsigned-integer-like type of the same width as *X*. For an expression *x* of type *X*, *to-unsigned-like(x)* is *x* explicitly converted to *make-unsigned-like-t<X>*.

Also within this Clause, *make-signed-like-t*<X> for an integer-like type X denotes `make_signed_t<X>` if X is an integer type; otherwise, it denotes a corresponding unspecified signed-integer-like type of the same width as X.

26.3 Range access

[range.access]

26.3.1 General

[range.access.general]

In addition to being available via inclusion of the `<ranges>` header, the customization point objects in 26.3 are available when `<iterator>` (25.2) is included.

Within 26.3, the *reified object* of a subexpression E denotes

- the same object as E if E is a glvalue, or
- the result of applying the temporary materialization conversion (7.3.5) to E otherwise.

26.3.2 `ranges::begin`

[range.access.begin]

The name `ranges::begin` denotes a customization point object (16.3.3.3.5).

Given a subexpression E with type T, let `t` be an lvalue that denotes the reified object for E. Then:

- If E is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::begin(E)` is ill-formed.
- Otherwise, if T is an array type (9.3.4.5) and `remove_all_extents_t<T>` is an incomplete type, `ranges::begin(E)` is ill-formed with no diagnostic required.
- Otherwise, if T is an array type, `ranges::begin(E)` is expression-equivalent to `t + 0`.
- Otherwise, if `auto(t.begin())` is a valid expression whose type models `input_or_output_iterator`, `ranges::begin(E)` is expression-equivalent to `auto(t.begin())`.
- Otherwise, if T is a class or enumeration type and `auto(begin(t))` is a valid expression whose type models `input_or_output_iterator` where the meaning of `begin` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::begin(E)` is expression-equivalent to that expression.
- Otherwise, `ranges::begin(E)` is ill-formed.

NOTE 1 Diagnosable ill-formed cases above result in substitution failure when `ranges::begin(E)` appears in the immediate context of a template instantiation.

NOTE 2 Whenever `ranges::begin(E)` is a valid expression, its type models `input_or_output_iterator`.

26.3.3 `ranges::end`

[range.access.end]

The name `ranges::end` denotes a customization point object (16.3.3.3.5).

Given a subexpression E with type T, let `t` be an lvalue that denotes the reified object for E. Then:

- If E is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::end(E)` is ill-formed.
- Otherwise, if T is an array type (9.3.4.5) and `remove_all_extents_t<T>` is an incomplete type, `ranges::end(E)` is ill-formed with no diagnostic required.
- Otherwise, if T is an array of unknown bound, `ranges::end(E)` is ill-formed.
- Otherwise, if T is an array, `ranges::end(E)` is expression-equivalent to `t + extent_v<T>`.
- Otherwise, if `auto(t.end())` is a valid expression whose type models `sentinel_for<iterator_t<T>>` then `ranges::end(E)` is expression-equivalent to `auto(t.end())`.
- Otherwise, if T is a class or enumeration type and `auto(end(t))` is a valid expression whose type models `sentinel_for<iterator_t<T>>` where the meaning of `end` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::end(E)` is expression-equivalent to that expression.
- Otherwise, `ranges::end(E)` is ill-formed.

NOTE 1 Diagnosable ill-formed cases above result in substitution failure when `ranges::end(E)` appears in the immediate context of a template instantiation.

NOTE 2 Whenever `ranges::end(E)` is a valid expression, the types S and I of `ranges::end(E)` and `ranges::begin(E)` model `sentinel_for<S, I>`.

26.3.4 ranges::cbegin**[range.access.cbegin]**

The name `ranges::cbegin` denotes a customization point object (16.3.3.3.5). Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

- If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::cbegin(E)` is ill-formed.
- Otherwise, let `U` be `ranges::begin(possibly-const-range(t))`. `ranges::cbegin(E)` is expression-equivalent to `const_iterator<decltype(U)>(U)`.

NOTE Whenever `ranges::cbegin(E)` is a valid expression, its type models `input_or_output_iterator` and `constant_iterator`.

26.3.5 ranges::cend**[range.access.cend]**

The name `ranges::cend` denotes a customization point object (16.3.3.3.5). Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

- If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::cend(E)` is ill-formed.
- Otherwise, let `U` be `ranges::end(possibly-const-range(t))`. `ranges::cend(E)` is expression-equivalent to `const_sentinel<decltype(U)>(U)`.

NOTE Whenever `ranges::cend(E)` is a valid expression, the types `S` and `I` of the expressions `ranges::cend(E)` and `ranges::cbegin(E)` model `sentinel_for<S, I>`. If `S` models `input_iterator`, then `S` also models `constant_iterator`.

26.3.6 ranges::rbegin**[range.access.rbegin]**

The name `ranges::rbegin` denotes a customization point object (16.3.3.3.5).

Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

- If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::rbegin(E)` is ill-formed.
- Otherwise, if `T` is an array type (9.3.4.5) and `remove_all_extents_t<T>` is an incomplete type, `ranges::rbegin(E)` is ill-formed with no diagnostic required.
- Otherwise, if `auto(t.rbegin())` is a valid expression whose type models `input_or_output_iterator`, `ranges::rbegin(E)` is expression-equivalent to `auto(t.rbegin())`.
- Otherwise, if `T` is a class or enumeration type and `auto(rbegin(t))` is a valid expression whose type models `input_or_output_iterator` where the meaning of `rbegin` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::rbegin(E)` is expression-equivalent to that expression.
- Otherwise, if both `ranges::begin(t)` and `ranges::end(t)` are valid expressions of the same type which models `bidirectional_iterator` (25.3.4.12), `ranges::rbegin(E)` is expression-equivalent to `make_reverse_iterator(ranges::end(t))`.
- Otherwise, `ranges::rbegin(E)` is ill-formed.

NOTE 1 Diagnosable ill-formed cases above result in substitution failure when `ranges::rbegin(E)` appears in the immediate context of a template instantiation.

NOTE 2 Whenever `ranges::rbegin(E)` is a valid expression, its type models `input_or_output_iterator`.

26.3.7 ranges::rend**[range.access.rend]**

The name `ranges::rend` denotes a customization point object (16.3.3.3.5).

Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

- If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::rend(E)` is ill-formed.
- Otherwise, if `T` is an array type (9.3.4.5) and `remove_all_extents_t<T>` is an incomplete type, `ranges::rend(E)` is ill-formed with no diagnostic required.
- Otherwise, if `auto(t.rend())` is a valid expression whose type models `sentinel_for<decltype(ranges::rbegin(E))>` then `ranges::rend(E)` is expression-equivalent to `auto(t.rend())`.

- Otherwise, if *T* is a class or enumeration type and `auto(rend(t))` is a valid expression whose type models `sentinel_for<decltype(ranges::rbegin(E))>` where the meaning of `rend` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::rend(E)` is expression-equivalent to that expression.
- Otherwise, if both `ranges::begin(t)` and `ranges::end(t)` are valid expressions of the same type which models `bidirectional_iterator` (25.3.4.12), then `ranges::rend(E)` is expression-equivalent to `make_reverse_iterator(ranges::begin(t))`.
- Otherwise, `ranges::rend(E)` is ill-formed.

NOTE 1 Diagnosable ill-formed cases above result in substitution failure when `ranges::rend(E)` appears in the immediate context of a template instantiation.

NOTE 2 Whenever `ranges::rend(E)` is a valid expression, the types *S* and *I* of the expressions `ranges::rend(E)` and `ranges::rbegin(E)` model `sentinel_for<S, I>`.

26.3.8 `ranges::crbegin`

[range.access.crbegin]

The name `ranges::crbegin` denotes a customization point object (16.3.3.3.5). Given a subexpression *E* with type *T*, let *t* be an lvalue that denotes the reified object for *E*. Then:

- If *E* is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::crbegin(E)` is ill-formed.
- Otherwise, let *U* be `ranges::rbegin(possibly-const-range(t))`. `ranges::crbegin(E)` is expression-equivalent to `const_iterator<decltype(U)>(U)`.

NOTE Whenever `ranges::crbegin(E)` is a valid expression, its type models `input_or_output_iterator` and `constant_iterator`.

26.3.9 `ranges::crend`

[range.access.crend]

The name `ranges::crend` denotes a customization point object (16.3.3.3.5). Given a subexpression *E* with type *T*, let *t* be an lvalue that denotes the reified object for *E*. Then:

- If *E* is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::crend(E)` is ill-formed.
- Otherwise, let *U* be `ranges::rend(possibly-const-range(t))`. `ranges::crend(E)` is expression-equivalent to `const_sentinel<decltype(U)>(U)`.

NOTE Whenever `ranges::crend(E)` is a valid expression, the types *S* and *I* of the expressions `ranges::crend(E)` and `ranges::crbegin(E)` model `sentinel_for<S, I>`. If *S* models `input_iterator`, then *S* also models `constant_iterator`.

26.3.10 `ranges::size`

[range.prim.size]

The name `ranges::size` denotes a customization point object (16.3.3.3.5).

Given a subexpression *E* with type *T*, let *t* be an lvalue that denotes the reified object for *E*. Then:

- If *T* is an array of unknown bound (9.3.4.5), `ranges::size(E)` is ill-formed.
- Otherwise, if *T* is an array type, `ranges::size(E)` is expression-equivalent to `auto(extent_v<T>)`.
- Otherwise, if `disable_sized_range<remove_cv_t<T>>` (26.4.3) is false and `auto(t.size())` is a valid expression of integer-like type (25.3.4.4), `ranges::size(E)` is expression-equivalent to `auto(t.size())`.
- Otherwise, if *T* is a class or enumeration type, `disable_sized_range<remove_cv_t<T>>` is false and `auto(size(t))` is a valid expression of integer-like type where the meaning of `size` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::size(E)` is expression-equivalent to that expression.
- Otherwise, if `to-unsigned-like(ranges::end(t) - ranges::begin(t))` (26.2) is a valid expression and the types *I* and *S* of `ranges::begin(t)` and `ranges::end(t)` (respectively) model both `sized_sentinel_for<S, I>` (25.3.4.8) and `forward_iterator<I>`, then `ranges::size(E)` is expression-equivalent to `to-unsigned-like(ranges::end(t) - ranges::begin(t))`.
- Otherwise, `ranges::size(E)` is ill-formed.

NOTE 1 Diagnosable ill-formed cases above result in substitution failure when `ranges::size(E)` appears in the immediate context of a template instantiation.

NOTE 2 Whenever `ranges::size(E)` is a valid expression, its type is integer-like.

26.3.11 `ranges::ssize`

[range.prim.ssize]

The name `ranges::ssize` denotes a customization point object (16.3.3.3.5).

Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. If `ranges::size(t)` is ill-formed, `ranges::ssize(E)` is ill-formed. Otherwise let `D` be *make-signed-like-t* <decltype(`ranges::size(t)`)>, or `ptrdiff_t` if it is wider than that type; `ranges::ssize(E)` is expression-equivalent to `static_cast<D>(ranges::size(t))`.

26.3.12 `ranges::empty`

[range.prim.empty]

The name `ranges::empty` denotes a customization point object (16.3.3.3.5).

Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

- If `T` is an array of unknown bound (9.3.4.5), `ranges::empty(E)` is ill-formed.
- Otherwise, if `bool(t.empty())` is a valid expression, `ranges::empty(E)` is expression-equivalent to `bool(t.empty())`.
- Otherwise, if `(ranges::size(t) == 0)` is a valid expression, `ranges::empty(E)` is expression-equivalent to `(ranges::size(t) == 0)`.
- Otherwise, if `bool(ranges::begin(t) == ranges::end(t))` is a valid expression and the type of `ranges::begin(t)` models `forward_iterator`, `ranges::empty(E)` is expression-equivalent to `bool(ranges::begin(t) == ranges::end(t))`.
- Otherwise, `ranges::empty(E)` is ill-formed.

NOTE 1 Diagnosable ill-formed cases above result in substitution failure when `ranges::empty(E)` appears in the immediate context of a template instantiation.

NOTE 2 Whenever `ranges::empty(E)` is a valid expression, it has type `bool`.

26.3.13 `ranges::data`

[range.prim.data]

The name `ranges::data` denotes a customization point object (16.3.3.3.5).

Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

- If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::data(E)` is ill-formed.
- Otherwise, if `T` is an array type (9.3.4.5) and `remove_all_extents_t<T>` is an incomplete type, `ranges::data(E)` is ill-formed with no diagnostic required.
- Otherwise, if `auto(t.data())` is a valid expression of pointer to object type, `ranges::data(E)` is expression-equivalent to `auto(t.data())`.
- Otherwise, if `ranges::begin(t)` is a valid expression whose type models `contiguous_iterator`, `ranges::data(E)` is expression-equivalent to `to_address(ranges::begin(t))`.
- Otherwise, `ranges::data(E)` is ill-formed.

NOTE 1 Diagnosable ill-formed cases above result in substitution failure when `ranges::data(E)` appears in the immediate context of a template instantiation.

NOTE 2 Whenever `ranges::data(E)` is a valid expression, it has pointer to object type.

26.3.14 `ranges::cdata`

[range.prim.cdata]

```
template<class T>
constexpr auto as-const-pointer(const T* p) { return p; } // exposition only
```

The name `ranges::cdata` denotes a customization point object (16.3.3.3.5). Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

- If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::cdata(E)` is ill-formed.
- Otherwise, `ranges::cdata(E)` is expression-equivalent to `as-const-pointer(ranges::data(possibly-const-range(t)))`.

NOTE Whenever `ranges::cdata(E)` is a valid expression, it has pointer to constant object type.

26.4 Range requirements

[range.req]

26.4.1 General

[range.req.general]

Ranges are an abstraction that allows a C++ program to operate on elements of data structures uniformly. Calling `ranges::begin` on a range returns an object whose type models `input_or_output_iterator` (25.3.4.6). Calling `ranges::end` on a range returns an object whose type `S`, together with the type `I` of the object returned by `ranges::begin`, models `sentinel_for<S, I>`. The library formalizes the interfaces, semantics, and complexity of ranges to enable algorithms and range adaptors that work efficiently on different types of sequences.

The `range` concept requires that `ranges::begin` and `ranges::end` return an iterator and a sentinel, respectively. The `sized_range` concept refines `range` with the requirement that `ranges::size` be amortized $\mathcal{O}(1)$. The `view` concept specifies requirements on a `range` type to provide operations with predictable complexity.

Several refinements of `range` group requirements that arise frequently in concepts and algorithms. Common ranges are ranges for which `ranges::begin` and `ranges::end` return objects of the same type. Random access ranges are ranges for which `ranges::begin` returns a type that models `random_access_iterator` (25.3.4.13). (Contiguous, bidirectional, forward, input, and output ranges are defined similarly.) Viewable ranges can be converted to views.

26.4.2 Ranges

[range.range]

The `range` concept defines the requirements of a type that allows iteration over its elements by providing an iterator and sentinel that denote the elements of the range.

```
template<class T>
concept range =
    requires(T& t) {
        ranges::begin(t);           // sometimes equality-preserving (see below)
        ranges::end(t);
    };

```

The required expressions `ranges::begin(t)` and `ranges::end(t)` of the `range` concept do not require implicit expression variations (18.2).

Given an expression `t` such that `decltype(t)` is `T&`, `T` models `range` only if

- `[ranges::begin(t), ranges::end(t))` denotes a range (25.3.1),
- both `ranges::begin(t)` and `ranges::end(t)` are amortized constant time and non-modifying, and
- if the type of `ranges::begin(t)` models `forward_iterator`, `ranges::begin(t)` is equality-preserving.

NOTE 1 Equality preservation of both `ranges::begin` and `ranges::end` enables passing a range whose iterator type models `forward_iterator` to multiple algorithms and making multiple passes over the range by repeated calls to `ranges::begin` and `ranges::end`. Since `ranges::begin` is not required to be equality-preserving when the return type does not model `forward_iterator`, it is possible for repeated calls to not return equal values or to not be well-defined.

```
template<class T>
concept borrowed_range =
    range<T> && (is_lvalue_reference_v<T> || enable_borrowed_range<remove_cvref_t<T>>);

```

Let `U` be `remove_reference_t<T>` if `T` is an rvalue reference type, and `T` otherwise. Given a variable `u` of type `U`, `T` models `borrowed_range` only if the validity of iterators obtained from `u` is not tied to the lifetime of that variable.

NOTE 2 Since the validity of iterators is not tied to the lifetime of a variable whose type models `borrowed_range`, a function with a parameter of such a type can return iterators obtained from it without danger of dangling.

```
template<class>
constexpr bool enable_borrowed_range = false;

```

Remarks: Pursuant to 16.4.5.2.1, users may specialize `enable_borrowed_range` for cv-unqualified program-defined types. Such specializations shall be usable in constant expressions (7.7) and have type `const bool`.

EXAMPLE Each specialization **S** of class template **subrange** (26.5.4) models **borrowed_range** because

- **enable_borrowed_range<S>** is specialized to have the value **true**, and
- **S**'s iterators do not have validity tied to the lifetime of an **S** object because they are “borrowed” from some other range.

26.4.3 Sized ranges

[range.sized]

The **sized_range** concept refines **range** with the requirement that the number of elements in the range can be determined in amortized constant time using **ranges::size**.

```
template<class T>
concept sized_range =
    range<T> && requires(T& t) { ranges::size(t); };
```

Given an lvalue **t** of type **remove_reference_t<T>**, **T** models **sized_range** only if

- **ranges::size(t)** is amortized $\mathcal{O}(1)$, does not modify **t**, and is equal to **ranges::distance(ranges::begin(t), ranges::end(t))**, and
- if **iterator_t<T>** models **forward_iterator**, **ranges::size(t)** is well-defined regardless of the evaluation of **ranges::begin(t)**.

NOTE 1 **ranges::size(t)** is otherwise not required to be well-defined after evaluating **ranges::begin(t)**. For example, it is possible for **ranges::size(t)** to be well-defined for a **sized_range** whose iterator type does not model **forward_iterator** only if evaluated before the first call to **ranges::begin(t)**.

```
template<class>
constexpr bool disable_sized_range = false;
```

Remarks: Pursuant to 16.4.5.2.1, users may specialize **disable_sized_range** for cv-unqualified program-defined types. Such specializations shall be usable in constant expressions (7.7) and have type **const bool**.

NOTE 2 **disable_sized_range** allows use of range types with the library that satisfy but do not in fact model **sized_range**.

26.4.4 Views

[range.view]

The **view** concept specifies the requirements of a **range** type that has the semantic properties below, which make it suitable for use in constructing range adaptor pipelines (26.7).

```
template<class T>
concept view =
    range<T> && movable<T> && enable_view<T>;
```

T models **view** only if

- **T** has $\mathcal{O}(1)$ move construction; and
- move assignment of an object of type **T** is no more complex than destruction followed by move construction; and
- if **N** copies and/or moves are made from an object of type **T** that contained **M** elements, then those **N** objects have $\mathcal{O}(N + M)$ destruction; and
- **copy_constructible<T>** is **false**, or **T** has $\mathcal{O}(1)$ copy construction; and
- **copyable<T>** is **false**, or copy assignment of an object of type **T** is no more complex than destruction followed by copy construction.

NOTE The constraints on copying and moving imply that a moved-from object of type **T** has $\mathcal{O}(1)$ destruction.

EXAMPLE Examples of views are:

- A **range** type that wraps a pair of iterators.
- A **range** type that holds its elements by **shared_ptr** and shares ownership with all its copies.
- A **range** type that generates its elements on demand.

A container such as **vector<string>** does not meet the semantic requirements of **view** since copying the container copies all of the elements, which cannot be done in constant time.

Since the difference between **range** and **view** is largely semantic, the two are differentiated with the help of **enable_view**.

```
template<class T>
constexpr bool is-derived-from-view-interface = see below;           // exposition only
template<class T>
constexpr bool enable_view =
    derived_from<T, view_base> || is-derived-from-view-interface<T>;
```

For a type T, *is-derived-from-view-interface*<T> is true if and only if T has exactly one public base class **view_interface**<U> for some type U and T has no base classes of type **view_interface**<V> for any other type V.

Remarks: Pursuant to 16.4.5.2.1, users may specialize **enable_view** to **true** for cv-unqualified program-defined types which model **view**, and **false** for types which do not. Such specializations shall be usable in constant expressions (7.7) and have type **const bool**.

26.4.5 Other range refinements

[range.refinements]

The **output_range** concept specifies requirements of a **range** type for which **ranges::begin** returns a model of **output_iterator** (25.3.4.10). **input_range**, **forward_range**, **bidirectional_range**, and **random_access_range** are defined similarly.

```
template<class R, class T>
concept output_range =
    range<R> && output_iterator<iterator_t<R>, T>;

template<class T>
concept input_range =
    range<T> && input_iterator<iterator_t<T>>;

template<class T>
concept forward_range =
    input_range<T> && forward_iterator<iterator_t<T>>;

template<class T>
concept bidirectional_range =
    forward_range<T> && bidirectional_iterator<iterator_t<T>>;

template<class T>
concept random_access_range =
    bidirectional_range<T> && random_access_iterator<iterator_t<T>>;
```

contiguous_range additionally requires that the **ranges::data** customization point object (26.3.13) is usable with the range.

```
template<class T>
concept contiguous_range =
    random_access_range<T> && contiguous_iterator<iterator_t<T>> &&
    requires (T& t) {
        { ranges::data(t) } -> same_as<add_pointer_t<range_reference_t<T>>>;
    };
};
```

Given an expression t such that **decltype(t)** is T&, T models **contiguous_range** only if **to_address(ranges::begin(t)) == ranges::data(t)** is true.

The **common_range** concept specifies requirements of a **range** type for which **ranges::begin** and **ranges::end** return objects of the same type.

EXAMPLE The standard containers (Clause 24) model **common_range**.

```
template<class T>
concept common_range =
    range<T> && same_as<iterator_t<T>, sentinel_t<T>>;
```

```
template<class R>
constexpr bool is-initializer-list = see below;           // exposition only
```

For a type *R*, *is-initializer-list*<*R*> is true if and only if *remove_cvref_t*<*R*> is a specialization of *initializer_list*.

The *viewable_range* concept specifies the requirements of a *range* type that can be converted to a view safely.

```
template<class T>
concept viewable_range =
    range<T> &&
    ((view<remove_cvref_t<T>> && constructible_from<remove_cvref_t<T>, T>) ||
     (!view<remove_cvref_t<T>> &&
      (is_lvalue_reference_v<T> || (movable<remove_reference_t<T>> && !is-initializer-list<T>))));
```

The *constant_range* concept specifies the requirements of a *range* type whose elements are not modifiable.

```
template<class T>
concept constant_range =
    input_range<T> && constant_iterator<iterator_t<T>>;
```

26.5 Range utilities [range.utility]

26.5.1 General [range.utility.general]

The components in 26.5 are general utilities for representing and manipulating ranges.

26.5.2 Helper concepts [range.utility.helpers]

Many of the types in 26.5 are specified in terms of the following exposition-only concepts:

```
template<class R>
concept simple-view =                                     // exposition only
    view<R> && range<const R> &&
    same_as<iterator_t<R>, iterator_t<const R>> &&
    same_as<sentinel_t<R>, sentinel_t<const R>>;

template<class I>
concept has-arrow =                                     // exposition only
    input_iterator<I> && (is_pointer_v<I> || requires(I i) { i.operator->(); });

template<class T, class U>
concept different-from =                                 // exposition only
    !same_as<remove_cvref_t<T>, remove_cvref_t<U>>;

template<class R>
concept range-with-movable-references =                 // exposition only
    input_range<R> && move_constructible<range_reference_t<R>> &&
    move_constructible<range_rvalue_reference_t<R>>;
```

26.5.3 View interface [view.interface]

26.5.3.1 General [view.interface.general]

The class template *view_interface* is a helper for defining view-like types that offer a container-like interface. It is parameterized with the type that is derived from it.

```
namespace std::ranges {
    template<class D>
        requires is_class_v<D> && same_as<D, remove_cv_t<D>>
        class view_interface {
        private:
            constexpr D& derived() noexcept {             // exposition only
                return static_cast<D&>(*this);
            }
            constexpr const D& derived() const noexcept {  // exposition only
                return static_cast<const D&>(*this);
            }
        };
}
```

```

public:
constexpr bool empty() requires sized_range<D> || forward_range<D> {
    if constexpr (sized_range<D>)
        return ranges::size(derived()) == 0;
    else
        return ranges::begin(derived()) == ranges::end(derived());
}
constexpr bool empty() const requires sized_range<const D> || forward_range<const D> {
    if constexpr (sized_range<const D>)
        return ranges::size(derived()) == 0;
    else
        return ranges::begin(derived()) == ranges::end(derived());
}

constexpr auto cbegin() requires input_range<D> {
    return ranges::cbegin(derived());
}
constexpr auto cbegin() const requires input_range<const D> {
    return ranges::cbegin(derived());
}
constexpr auto cend() requires input_range<D> {
    return ranges::cend(derived());
}
constexpr auto cend() const requires input_range<const D> {
    return ranges::cend(derived());
}

constexpr explicit operator bool()
    requires requires { ranges::empty(derived()); } {
    return !ranges::empty(derived());
}
constexpr explicit operator bool() const
    requires requires { ranges::empty(derived()); } {
    return !ranges::empty(derived());
}

constexpr auto data() requires contiguous_iterator<iterator_t<D>> {
    return to_address(ranges::begin(derived()));
}
constexpr auto data() const
    requires range<const D> && contiguous_iterator<iterator_t<const D>> {
    return to_address(ranges::begin(derived()));
}

constexpr auto size() requires forward_range<D> &&
    sized_sentinel_for<sentinel_t<D>, iterator_t<D>> {
    return to-unsigned-like(ranges::end(derived()) - ranges::begin(derived()));
}
constexpr auto size() const requires forward_range<const D> &&
    sized_sentinel_for<sentinel_t<const D>, iterator_t<const D>> {
    return to-unsigned-like(ranges::end(derived()) - ranges::begin(derived()));
}

constexpr decltype(auto) front() requires forward_range<D>;
constexpr decltype(auto) front() const requires forward_range<const D>;

constexpr decltype(auto) back() requires bidirectional_range<D> && common_range<D>;
constexpr decltype(auto) back() const
    requires bidirectional_range<const D> && common_range<const D>;

template<random_access_range R = D>
constexpr decltype(auto) operator[] (range_difference_t<R> n) {
    return ranges::begin(derived())[n];
}

```

```

template<random_access_range R = const D>
constexpr decltype(auto) operator[](range_difference_t<R> n) const {
    return ranges::begin(derived())[n];
}
};
}

```

The template parameter `D` for `view_interface` may be an incomplete type. Before any member of the resulting specialization of `view_interface` other than special member functions is referenced, `D` shall be complete, and model both `derived_from<view_interface<D>>` and `view`.

26.5.3.2 Members

[view.interface.members]

```

constexpr decltype(auto) front() requires forward_range<D>;
constexpr decltype(auto) front() const requires forward_range<const D>;

```

Preconditions: `!empty()` is true.

Effects: Equivalent to: `return *ranges::begin(derived());`

```

constexpr decltype(auto) back() requires bidirectional_range<D> && common_range<D>;
constexpr decltype(auto) back() const
requires bidirectional_range<const D> && common_range<const D>;

```

Preconditions: `!empty()` is true.

Effects: Equivalent to: `return *ranges::prev(ranges::end(derived()));`

26.5.4 Sub-ranges

[range.subrange]

26.5.4.1 General

[range.subrange.general]

The `subrange` class template combines together an iterator and a sentinel into a single object that models the `view` concept. Additionally, it models the `sized_range` concept when the final template parameter is `subrange_kind::sized`.

```

namespace std::ranges {
    template<class From, class To>
        concept uses_nonqualification_pointer_conversion = // exposition only
            is_pointer_v<From> && is_pointer_v<To> &&
            !convertible_to<remove_pointer_t<From>(*), remove_pointer_t<To>(*)[]>;

    template<class From, class To>
        concept convertible_to_non_slicing = // exposition only
            convertible_to<From, To> &&
            !uses_nonqualification_pointer_conversion<decay_t<From>, decay_t<To>>;

    template<class T, class U, class V>
        concept pair_like_convertible_from = // exposition only
            !range<T> && !is_reference_v<T> && pair_like<T> &&
            constructible_from<T, U, V> &&
            convertible_to_non_slicing<U, tuple_element_t<0, T>> &&
            convertible_to<V, tuple_element_t<1, T>>;

    template<input_or_output_iterator I, sentinel_for<I> S = I, subrange_kind K =
        sized_sentinel_for<S, I> ? subrange_kind::sized : subrange_kind::unsized>
        requires (K == subrange_kind::sized || !sized_sentinel_for<S, I>)
        class subrange : public view_interface<subrange<I, S, K>> {
        private:
            static constexpr bool StoreSize = // exposition only
                K == subrange_kind::sized && !sized_sentinel_for<S, I>;
            I begin_ = I(); // exposition only
            S end_ = S(); // exposition only
            make_unsigned_like_t<iter_difference_t<I>> size_ = 0; // exposition only; present only
                                                                    // if StoreSize is true
        public:
            subrange() requires default_initializable<I> = default;

            constexpr subrange(convertible_to_non_slicing<I> auto i, S s) requires (!StoreSize);

```

```

constexpr subrange(convertible-to-non-slicing<I> auto i, S s,
    make-unsigned-like-t<iter_difference_t<I>> n)
    requires (K == subrange_kind::sized);

template<different-from<subrange> R>
    requires borrowed_range<R> &&
        convertible-to-non-slicing<iterator_t<R>, I> &&
        convertible_to<sentinel_t<R>, S>
constexpr subrange(R&& r) requires (!StoreSize || sized_range<R>);

template<borrowed_range R>
    requires convertible-to-non-slicing<iterator_t<R>, I> &&
        convertible_to<sentinel_t<R>, S>
constexpr subrange(R&& r, make-unsigned-like-t<iter_difference_t<I>> n)
    requires (K == subrange_kind::sized)
    : subrange{ranges::begin(r), ranges::end(r), n} {}

template<different-from<subrange> PairLike>
    requires pair-like-convertible-from<PairLike, const I&, const S&>
constexpr operator PairLike() const;

constexpr I begin() const requires copyable<I>;
[[nodiscard]] constexpr I begin() requires (!copyable<I>);
constexpr S end() const;

constexpr bool empty() const;
constexpr make-unsigned-like-t<iter_difference_t<I>> size() const
    requires (K == subrange_kind::sized);

[[nodiscard]] constexpr subrange next(iter_difference_t<I> n = 1) const &
    requires forward_iterator<I>;
[[nodiscard]] constexpr subrange next(iter_difference_t<I> n = 1) &&;
[[nodiscard]] constexpr subrange prev(iter_difference_t<I> n = 1) const
    requires bidirectional_iterator<I>;
constexpr subrange& advance(iter_difference_t<I> n);
};

template<input_or_output_iterator I, sentinel_for<I> S>
    subrange(I, S) -> subrange<I, S>;

template<input_or_output_iterator I, sentinel_for<I> S>
    subrange(I, S, make-unsigned-like-t<iter_difference_t<I>>) ->
        subrange<I, S, subrange_kind::sized>;

template<borrowed_range R>
    subrange(R&&) ->
        subrange<iterator_t<R>, sentinel_t<R>,
            (sized_range<R> || sized_sentinel_for<sentinel_t<R>, iterator_t<R>>)
                ? subrange_kind::sized : subrange_kind::unsized>;

template<borrowed_range R>
    subrange(R&&, make-unsigned-like-t<range_difference_t<R>>) ->
        subrange<iterator_t<R>, sentinel_t<R>, subrange_kind::sized>;
}

```

26.5.4.2 Constructors and conversions

[range.subrange.ctor]

constexpr subrange(convertible-to-non-slicing<I> auto i, S s) requires (!StoreSize);

Preconditions: [i,s) is a valid range.

Effects: Initializes *begin_* with std::move(i) and *end_* with s.

```
constexpr subrange(convertible-to-non-slicing<I> auto i, S s,
                  make-unsigned-like-t<iter_difference_t<I>> n)
requires (K == subrange_kind::sized);
```

Preconditions: $[i, s)$ is a valid range, and $n == \text{to-unsigned-like}(\text{ranges::distance}(i, s))$ is true.

Effects: Initializes *begin_* with $\text{std::move}(i)$ and *end_* with *s*. If *StoreSize* is true, initializes *size_* with *n*.

NOTE Accepting the length of the range and storing it to later return from *size()* enables *subrange* to model *sized_range* even when it stores an iterator and sentinel that do not model *sized_sentinel_for*.

```
template<different-from<subrange> R>
requires borrowed_range<R> &&
         convertible-to-non-slicing<iterator_t<R>, I> &&
         convertible_to<sentinel_t<R>, S>
constexpr subrange(R&& r) requires (!StoreSize || sized_range<R>);
```

Effects: Equivalent to:

- If *StoreSize* is true, $\text{subrange}(r, \text{static\_cast}<\text{decltype}(\text{size\_})>(\text{ranges::size}(r)))$.
- Otherwise, $\text{subrange}(\text{ranges::begin}(r), \text{ranges::end}(r))$.

```
template<different-from<subrange> PairLike>
requires pair-like-convertible-from<PairLike, const I&, const S&>
constexpr operator PairLike() const;
```

Effects: Equivalent to: $\text{return PairLike}(\text{begin\_}, \text{end\_})$;

26.5.4.3 Accessors

[range.subrange.access]

```
constexpr I begin() const requires copyable<I>;
```

Effects: Equivalent to: return begin_ ;

```
[[nodiscard]] constexpr I begin() requires (!copyable<I>);
```

Effects: Equivalent to: $\text{return std::move}(\text{begin\_})$;

```
constexpr S end() const;
```

Effects: Equivalent to: return end_ ;

```
constexpr bool empty() const;
```

Effects: Equivalent to: $\text{return begin\_} == \text{end\_}$;

```
constexpr make-unsigned-like-t<iter_difference_t<I>> size() const
requires (K == subrange_kind::sized);
```

Effects:

- If *StoreSize* is true, equivalent to: return size_ ;
- Otherwise, equivalent to: $\text{return to-unsigned-like}(\text{end\_} - \text{begin\_})$;

```
[[nodiscard]] constexpr subrange next(iter_difference_t<I> n = 1) const &
requires forward_iterator<I>;
```

Effects: Equivalent to:

```
auto tmp = *this;
tmp.advance(n);
return tmp;
```

```
[[nodiscard]] constexpr subrange next(iter_difference_t<I> n = 1) &&;
```

Effects: Equivalent to:

```
advance(n);
return std::move(*this);
```

```
[[nodiscard]] constexpr subrange prev(iter_difference_t<I> n = 1) const
requires bidirectional_iterator<I>;
```

Effects: Equivalent to:

```
auto tmp = *this;
tmp.advance(-n);
return tmp;
```

```
constexpr subrange& advance(iter_difference_t<I> n);
```

Effects: Equivalent to:

```
if constexpr (bidirectional_iterator<I>) {
    if (n < 0) {
        ranges::advance(begin_, n);
        if constexpr (StoreSize)
            size_ += to-unsigned-like(-n);
        return *this;
    }

    auto d = n - ranges::advance(begin_, n, end_);
    if constexpr (StoreSize)
        size_ -= to-unsigned-like(d);
    return *this;
}
```

```
template<size_t N, class I, class S, subrange_kind K>
requires ((N == 0 && copyable<I>) || N == 1)
constexpr auto get(const subrange<I, S, K>& r);
template<size_t N, class I, class S, subrange_kind K>
requires (N < 2)
constexpr auto get(subrange<I, S, K>&& r);
```

Effects: Equivalent to:

```
if constexpr (N == 0)
    return r.begin();
else
    return r.end();
```

26.5.5 Dangling iterator handling

[range.dangling]

The type `dangling` is used together with the template aliases `borrowed_iterator_t` and `borrowed_subrange_t`. When an algorithm that typically returns an iterator into, or a subrange of, a range argument is called with an rvalue range argument that does not model `borrowed_range` (26.4.2), the return value possibly refers to a range whose lifetime has ended. In such cases, the type `dangling` is returned instead of an iterator or subrange.

```
namespace std::ranges {
    struct dangling {
        constexpr dangling() noexcept = default;
        constexpr dangling(auto&&...) noexcept {}
    };
}
```

EXAMPLE

```
vector<int> f();
auto result1 = ranges::find(f(), 42); // #1
static_assert(same_as<decltype(result1), ranges::dangling>);
auto vec = f();
auto result2 = ranges::find(vec, 42); // #2
static_assert(same_as<decltype(result2), vector<int>::iterator>);
auto result3 = ranges::find(ranges::subrange{vec}, 42); // #3
static_assert(same_as<decltype(result3), vector<int>::iterator>);
```

The call to `ranges::find` at #1 returns `ranges::dangling` since `f()` is an rvalue `vector`; it is possible for the `vector` to be destroyed before a returned iterator is dereferenced. However, the calls at #2 and #3 both return iterators since the lvalue `vec` and specializations of `subrange` model `borrowed_range`.

For a type `R` that models `range`:

- if `R` models `borrowed_range`, then `borrowed_iterator_t<R>` denotes `iterator_t<R>`, and `borrowed_subrange_t<R>` denotes `subrange<iterator_t<R>>`;
- otherwise, both `borrowed_iterator_t<R>` and `borrowed_subrange_t<R>` denote dangling.

26.5.6 Class template `elements_of`

[range.elementsof]

Specializations of `elements_of` encapsulate a range and act as a tag in overload sets to disambiguate when a range should be treated as a sequence rather than a single value.

EXAMPLE

```
template<bool YieldElements>
generator<any> f(ranges::input_range auto&& r) {
    if constexpr (YieldElements)
        co_yield ranges::elements_of(r);           // yield each element of r
    else
        co_yield r;                               // yield r as a single value
}

namespace std::ranges {
    template<range R, class Allocator = allocator<byte>>
    struct elements_of {
        [[no_unique_address]] R range;
        [[no_unique_address]] Allocator allocator = Allocator();
    };

    template<class R, class Allocator = allocator<byte>>
    elements_of(R&&, Allocator = Allocator()) -> elements_of<R&&, Allocator>;
}
```

26.5.7 Range conversions

[range.utility.conv]

26.5.7.1 General

[range.utility.conv.general]

The range conversion functions construct an object (usually a container) from a range, by using a constructor taking a range, a `from_range_t` tagged constructor, or a constructor taking a pair of iterators, or by inserting each element of the range into the default-constructed object.

`ranges::to` is applied recursively, allowing the conversion of a range of ranges.

EXAMPLE

```
string_view str = "the quick brown fox";
auto words = views::split(str, ' ') | to<vector<string>>();
// words is vector<string>{"the", "quick", "brown", "fox"}
```

Let `reservable-container` be defined as follows:

```
template<class Container>
constexpr bool reservable-container =           // exposition only
    sized_range<Container> &&
    requires (Container& c, range_size_t<Container> n) {
        c.reserve(n);
        { c.capacity() } -> same_as<decltype(n)>;
        { c.max_size() } -> same_as<decltype(n)>;
    };
};
```

Let `container-insertable` be defined as follows:

```
template<class Container, class Ref>
constexpr bool container-insertable =           // exposition only
    requires (Container& c, Ref&& ref) {
        requires (requires { c.push_back(std::forward<Ref>(ref)); } ||
            requires { c.insert(c.end(), std::forward<Ref>(ref)); });
    };
};
```

Let `container-inserter` be defined as follows:

```

template<class Ref, class Container>
constexpr auto container_inserter(Container& c) { // exposition only
    if constexpr (requires { c.push_back(declval<Ref>()); })
        return back_inserter(c);
    else
        return inserter(c, c.end());
}

```

26.5.7.2 ranges::to

[range.utility.conv.to]

```

template<class C, input_range R, class... Args> requires (!view<C>)
constexpr C to(R&& r, Args&&... args);

```

Mandates: C is a cv-unqualified class type.

Returns: An object of type C constructed from the elements of r in the following manner:

- If C does not satisfy input_range or convertible_to<range_reference_t<R>, range_value_t<C>> is true:
 - If constructible_from<C, R, Args...> is true:

```
C(std::forward<R>(r), std::forward<Args>(args)...)

```
 - Otherwise, if constructible_from<C, from_range_t, R, Args...> is true:

```
C(from_range, std::forward<R>(r), std::forward<Args>(args)...)

```
 - Otherwise, if
 - common_range<R> is true,
 - the *qualified-id* iterator_traits<iterator_t<R>>::iterator_category is valid and denotes a type that models derived_from<input_iterator_tag>, and
 - constructible_from<C, iterator_t<R>, sentinel_t<R>, Args...> is true:

```
C(ranges::begin(r), ranges::end(r), std::forward<Args>(args)...)

```
 - Otherwise, if
 - constructible_from<C, Args...> is true, and
 - container_insettable<C, range_reference_t<R>> is true:

```
C c(std::forward<Args>(args)...)
if constexpr (sized_range<R> && reservable_container<C>)
    c.reserve(static_cast<range_size_t<C>>(ranges::size(r)));
ranges::copy(r, container_inserter<range_reference_t<R>>(c));

```
- Otherwise, if input_range<range_reference_t<R>> is true:

```

to<C>(r | views::transform([](auto&& elem) {
    return to<range_value_t<C>>(std::forward<decltype(elem)>(elem));
}), std::forward<Args>(args)...)

```
- Otherwise, the program is ill-formed.

```

template<template<class...> class C, input_range R, class... Args>
constexpr auto to(R&& r, Args&&... args);

```

Let *input-iterator* be an exposition-only type:

```

struct input_iterator { // exposition only
    using iterator_category = input_iterator_tag;
    using value_type = range_value_t<R>;
    using difference_type = ptrdiff_t;
    using pointer = add_pointer_t<range_reference_t<R>>;
    using reference = range_reference_t<R>;
    reference operator*() const;
    pointer operator->() const;
    input_iterator& operator++();
    input_iterator operator++(int);
    bool operator==(const input_iterator&) const;
};

```

NOTE *input-iterator* meets the syntactic requirements of *Cpp17InputIterator*.

Let *DEDUCE_EXPR* be defined as follows:

- `C(declval<R>(), declval<Args>()...)` if that is a valid expression,
- otherwise, `C(from_range, declval<R>(), declval<Args>()...)` if that is a valid expression,
- otherwise,
 - `C(declval<input-iterator>(), declval<input-iterator>(), declval<Args>()...)`
 - if that is a valid expression,
- otherwise, the program is ill-formed.

Returns: `to<decltype(DEDUCE_EXPR)>(std::forward<R>(r), std::forward<Args>(args)...).`

26.5.7.3 `ranges::to` adaptors

[range.utility.conv.adaptors]

```
template<class C, class... Args> requires (!view<C>)
constexpr auto to(Args&&... args);
template<template<class...> class C, class... Args>
constexpr auto to(Args&&... args);
```

Mandates: For the first overload, *C* is a cv-unqualified class type.

Returns: A range adaptor closure object (26.7.2) *f* that is a perfect forwarding call wrapper (22.10.4) with the following properties:

- It has no target object.
- Its bound argument entities `bound_args` consist of objects of types `decay_t<Args>...` direct-non-list-initialized with `std::forward<Args>(args)...`, respectively.
- Its call pattern is `to<C>(r, bound_args...)`, where *r* is the argument used in a function call expression of *f*.

26.6 Range factories

[range.factories]

26.6.1 General

[range.factories.general]

Subclause 26.6 defines *range factories*, which are utilities to create a view.

Range factories are declared in namespace `std::ranges::views`.

26.6.2 Empty view

[range.empty]

26.6.2.1 Overview

[range.empty.overview]

`empty_view` produces a view of no elements of a particular type.

EXAMPLE

```
auto e = views::empty<int>;
static_assert(ranges::empty(e));
static_assert(0 == e.size());
```

26.6.2.2 Class template `empty_view`

[range.empty.view]

```
namespace std::ranges {
  template<class T>
    requires is_object_v<T>
    class empty_view : public view_interface<empty_view<T>> {
    public:
      static constexpr T* begin() noexcept { return nullptr; }
      static constexpr T* end() noexcept { return nullptr; }
      static constexpr T* data() noexcept { return nullptr; }
      static constexpr size_t size() noexcept { return 0; }
      static constexpr bool empty() noexcept { return true; }
    };
}
```

26.6.3 Single view

[range.single]

26.6.3.1 Overview

[range.single.overview]

`single_view` produces a view that contains exactly one element of a specified value.

The name `views::single` denotes a customization point object (16.3.3.3.5). Given a subexpression `E`, the expression `views::single(E)` is expression-equivalent to `single_view<decay_t<decltype((E))>>(E)`.

EXAMPLE

```
for (int i : views::single(4))
    cout << i;           // prints 4
```

26.6.3.2 Class template `single_view`

[range.single.view]

```
namespace std::ranges {
    template<move_constructible T>
        requires is_object_v<T>
        class single_view : public view_interface<single_view<T>> {
        private:
            movable_box<T> value_;           // exposition only (see 26.7.3)

        public:
            single_view() requires default_initializable<T> = default;
            constexpr explicit single_view(const T& t) requires copy_constructible<T>;
            constexpr explicit single_view(T&& t);
            template<class... Args>
                requires constructible_from<T, Args...>
                constexpr explicit single_view(in_place_t, Args&&... args);

            constexpr T* begin() noexcept;
            constexpr const T* begin() const noexcept;
            constexpr T* end() noexcept;
            constexpr const T* end() const noexcept;
            static constexpr size_t size() noexcept;
            constexpr T* data() noexcept;
            constexpr const T* data() const noexcept;
        };

        template<class T>
            single_view(T) -> single_view<T>;
    }

    constexpr explicit single_view(const T& t) requires copy_constructible<T>;
        Effects: Initializes value_ with t.

    constexpr explicit single_view(T&& t);
        Effects: Initializes value_ with std::move(t).

    template<class... Args>
        requires constructible_from<T, Args...>
        constexpr explicit single_view(in_place_t, Args&&... args);
        Effects: Initializes value_ as if by value_{in_place, std::forward<Args>(args)...}.

    constexpr T* begin() noexcept;
    constexpr const T* begin() const noexcept;
        Effects: Equivalent to: return data();

    constexpr T* end() noexcept;
    constexpr const T* end() const noexcept;
        Effects: Equivalent to: return data() + 1;

    static constexpr size_t size() noexcept;
        Effects: Equivalent to: return 1;
```

```
constexpr T* data() noexcept;
constexpr const T* data() const noexcept;
```

Effects: Equivalent to: `return value_.operator->();`

26.6.4 Iota view

[range.iota]

26.6.4.1 Overview

[range.iota.overview]

`iota_view` generates a sequence of elements by repeatedly incrementing an initial value.

The name `views::iota` denotes a customization point object (16.3.3.3.5). Given subexpressions `E` and `F`, the expressions `views::iota(E)` and `views::iota(E, F)` are expression-equivalent to `iota_view(E)` and `iota_view(E, F)`, respectively.

EXAMPLE

```
for (int i : views::iota(1, 10))
    cout << i << ' '; // prints 1 2 3 4 5 6 7 8 9
```

26.6.4.2 Class template `iota_view`

[range.iota.view]

```
namespace std::ranges {
    template<class I>
        concept decrementable = see below; // exposition only

    template<class I>
        concept advanceable = see below; // exposition only

    template<weakly_incrementable W, semiregular Bound = unreachable_sentinel_t>
        requires weakly-equality-comparable-with<W, Bound> && copyable<W>
        class iota_view : public view_interface<iota_view<W, Bound>> {
        private:
            // 26.6.4.3, class iota_view::iterator
            struct iterator; // exposition only

            // 26.6.4.4, class iota_view::sentinel
            struct sentinel; // exposition only

            W value_ = W(); // exposition only
            Bound bound_ = Bound(); // exposition only

        public:
            iota_view() requires default_initializable<W> = default;
            constexpr explicit iota_view(W value);
            constexpr explicit iota_view(type_identity_t<W> value, type_identity_t<Bound> bound);
            constexpr explicit iota_view(iterator first, see below last);

            constexpr iterator begin() const;
            constexpr auto end() const;
            constexpr iterator end() const requires same_as<W, Bound>;

            constexpr auto size() const requires see below;
        };

    template<class W, class Bound>
        requires (!is-integer-like<W> || !is-integer-like<Bound> ||
            (is-signed-integer-like<W> == is-signed-integer-like<Bound>))
        iota_view(W, Bound) -> iota_view<W, Bound>;
}
```

Let *IOTA-DIFF-T*(*W*) be defined as follows:

- If *W* is not an integral type, or if it is an integral type and `sizeof(iter_difference_t<W>)` is greater than `sizeof(W)`, then *IOTA-DIFF-T*(*W*) denotes `iter_difference_t<W>`.
- Otherwise, *IOTA-DIFF-T*(*W*) is a signed integer type of width greater than the width of *W* if such a type exists.

- Otherwise, $IOTA-DIFF-T(W)$ is an unspecified signed-integer-like type (25.3.4.4) of width not less than the width of W .

NOTE It is unspecified whether this type satisfies `weakly_incrementable`.

The exposition-only *decrementable* concept is equivalent to:

```
template<class I>
concept decrementable = // exposition only
    incrementable<I> && requires(I i) {
        { --i } -> same_as<I&&>;
        { i-- } -> same_as<I>;
    };

```

When an object is in the domain of both pre- and post-decrement, the object is said to be *decrementable*.

Let a and b be equal objects of type I . I models *decrementable* only if

- If a and b are decrementable, then the following are all true:
 - `addressof(--a) == addressof(a)`
 - `bool(a-- == b)`
 - `bool(((void)a--, a) == --b)`
 - `bool(++(--a) == b)`.
- If a and b are incrementable, then `bool(--(++a) == b)`.

The exposition-only *advanceable* concept is equivalent to:

```
template<class I>
concept advanceable = // exposition only
    decrementable<I> && totally_ordered<I> &&
    requires(I i, const I j, const IOTA-DIFF-T(I) n) {
        { i += n } -> same_as<I&&>;
        { i -= n } -> same_as<I&&>;
        I(j + n);
        I(n + j);
        I(j - n);
        { j - j } -> convertible_to<IOTA-DIFF-T(I)>;
    };

```

Let D be $IOTA-DIFF-T(I)$. Let a and b be objects of type I such that b is reachable from a after n applications of `++a`, for some value n of type D . I models *advanceable* only if

- `(a += n)` is equal to b .
- `addressof(a += n)` is equal to `addressof(a)`.
- `I(a + n)` is equal to `(a += n)`.
- For any two positive values x and y of type D , if `I(a + D(x + y))` is well-defined, then `I(a + D(x + y))` is equal to `I(I(a + x) + y)`.
- `I(a + D(0))` is equal to a .
- If `I(a + D(n - 1))` is well-defined, then `I(a + n)` is equal to `[] (I c) { return ++c; }(I(a + D(n - 1)))`.
- `(b += -n)` is equal to a .
- `(b -= n)` is equal to a .
- `addressof(b -= n)` is equal to `addressof(b)`.
- `I(b - n)` is equal to `(b -= n)`.
- `D(b - a)` is equal to n .
- `D(a - b)` is equal to `D(-n)`.
- `bool(a <= b)` is true.

```
constexpr explicit iota_view(W value);
```

Preconditions: Bound denotes `unreachable_sentinel_t` or `Bound()` is reachable from `value`. When `W` and `Bound` model `totally_ordered_with`, then `bool(value <= Bound())` is true.

Effects: Initializes `value_` with `value`.

```
constexpr explicit iota_view(type_identity_t<W> value, type_identity_t<Bound> bound);
```

Preconditions: Bound denotes `unreachable_sentinel_t` or `bound` is reachable from `value`. When `W` and `Bound` model `totally_ordered_with`, then `bool(value <= bound)` is true.

Effects: Initializes `value_` with `value` and `bound_` with `bound`.

```
constexpr explicit iota_view(iterator first, see below last);
```

Effects: Equivalent to:

- If `same_as<W, Bound>` is true, `iota_view(first.value_, last.value_)`.
- Otherwise, if Bound denotes `unreachable_sentinel_t`, `iota_view(first.value_, last)`.
- Otherwise, `iota_view(first.value_, last.bound_)`.

Remarks: The type of `last` is:

- If `same_as<W, Bound>` is true, `iterator`.
- Otherwise, if Bound denotes `unreachable_sentinel_t`, `Bound`.
- Otherwise, `sentinel`.

```
constexpr iterator begin() const;
```

Effects: Equivalent to: `return iterator{value_};`

```
constexpr auto end() const;
```

Effects: Equivalent to:

```
if constexpr (same_as<Bound, unreachable_sentinel_t>)
    return unreachable_sentinel;
else
    return sentinel{bound_};
```

```
constexpr iterator end() const requires same_as<W, Bound>;
```

Effects: Equivalent to: `return iterator{bound_};`

```
constexpr auto size() const requires see below;
```

Effects: Equivalent to:

```
if constexpr (is-integer-like<W> && is-integer-like<Bound>)
    return (value_ < 0)
        ? ((bound_ < 0)
            ? to-unsigned-like(-value_) - to-unsigned-like(-bound_)
            : to-unsigned-like(bound_) + to-unsigned-like(-value_))
        : to-unsigned-like(bound_) - to-unsigned-like(value_);
else
    return to-unsigned-like(bound_ - value_);
```

Remarks: The expression in the *requires-clause* is equivalent to:

```
(same_as<W, Bound> && advanceable<W>) || (is-integer-like<W> && is-integer-like<Bound>) ||
    sized_sentinel_for<Bound, W>
```

26.6.4.3 Class `iota_view::iterator`

[range.iota.iterator]

```
namespace std::ranges {
    template<weakly_incrementable W, semiregular Bound>
        requires weakly-equality-comparable-with<W, Bound> && copyable<W>
        struct iota_view<W, Bound>::iterator {
        private:
            W value_ = W();           // exposition only
```

```

public:
    using iterator_concept = see below;
    using iterator_category = input_iterator_tag;           // present only if W models incrementable and
                                                            // IOTA-DIFF-T(W) is an integral type

    using value_type = W;
    using difference_type = IOTA-DIFF-T(W);

    iterator() requires default_initializable<W> = default;
    constexpr explicit iterator(W value);

    constexpr W operator*() const noexcept(is_nothrow_copy_constructible_v<W>);

    constexpr iterator& operator++();
    constexpr void operator++(int);
    constexpr iterator operator++(int) requires incrementable<W>;

    constexpr iterator& operator--() requires decrementable<W>;
    constexpr iterator operator--(int) requires decrementable<W>;

    constexpr iterator& operator+=(difference_type n)
        requires advanceable<W>;
    constexpr iterator& operator-=(difference_type n)
        requires advanceable<W>;
    constexpr W operator[](difference_type n) const
        requires advanceable<W>;

    friend constexpr bool operator==(const iterator& x, const iterator& y)
        requires equality_comparable<W>;

    friend constexpr bool operator<(const iterator& x, const iterator& y)
        requires totally_ordered<W>;
    friend constexpr bool operator>(const iterator& x, const iterator& y)
        requires totally_ordered<W>;
    friend constexpr bool operator<=(const iterator& x, const iterator& y)
        requires totally_ordered<W>;
    friend constexpr bool operator>=(const iterator& x, const iterator& y)
        requires totally_ordered<W>;
    friend constexpr auto operator<=>(const iterator& x, const iterator& y)
        requires totally_ordered<W> && three_way_comparable<W>;

    friend constexpr iterator operator+(iterator i, difference_type n)
        requires advanceable<W>;
    friend constexpr iterator operator+(difference_type n, iterator i)
        requires advanceable<W>;

    friend constexpr iterator operator-(iterator i, difference_type n)
        requires advanceable<W>;
    friend constexpr difference_type operator-(const iterator& x, const iterator& y)
        requires advanceable<W>;
};
}

```

iterator::*iterator_concept* is defined as follows:

- If *W* models *advanceable*, then *iterator_concept* is *random_access_iterator_tag*.
- Otherwise, if *W* models *decrementable*, then *iterator_concept* is *bidirectional_iterator_tag*.
- Otherwise, if *W* models *incrementable*, then *iterator_concept* is *forward_iterator_tag*.
- Otherwise, *iterator_concept* is *input_iterator_tag*.

NOTE 1 Overloads for *iter_move* and *iter_swap* are omitted intentionally.

```
constexpr explicit iterator(W value);
```

Effects: Initializes *value_* with *value*.

```
constexpr W operator*() const noexcept(is_nothrow_copy_constructible_v<W>);
```

Effects: Equivalent to: `return value_;`

NOTE 2 The `noexcept` clause is needed by the default `iter_move` implementation.

```
constexpr iterator& operator++();
```

Effects: Equivalent to:

```
++value_;
return *this;
```

```
constexpr void operator++(int);
```

Effects: Equivalent to `++*this`.

```
constexpr iterator operator++(int) requires incrementable<W>;
```

Effects: Equivalent to:

```
auto tmp = *this;
++*this;
return tmp;
```

```
constexpr iterator& operator--() requires decrementable<W>;
```

Effects: Equivalent to:

```
--value_;
return *this;
```

```
constexpr iterator operator--(int) requires decrementable<W>;
```

Effects: Equivalent to:

```
auto tmp = *this;
--*this;
return tmp;
```

```
constexpr iterator& operator+=(difference_type n)
requires advanceable<W>;
```

Effects: Equivalent to:

```
if constexpr (is-integer-like<W> && !is-signed-integer-like<W>) {
    if (n >= difference_type(0))
        value_ += static_cast<W>(n);
    else
        value_ -= static_cast<W>(-n);
} else {
    value_ += n;
}
return *this;
```

```
constexpr iterator& operator-=(difference_type n)
requires advanceable<W>;
```

Effects: Equivalent to:

```
if constexpr (is-integer-like<W> && !is-signed-integer-like<W>) {
    if (n >= difference_type(0))
        value_ -= static_cast<W>(n);
    else
        value_ += static_cast<W>(-n);
} else {
    value_ -= n;
}
return *this;
```

```
constexpr W operator[](difference_type n) const
requires advanceable<W>;
```

Effects: Equivalent to: `return W(value_ + n);`

```
friend constexpr bool operator==(const iterator& x, const iterator& y)
    requires equality_comparable<W>;
```

Effects: Equivalent to: `return x.value_ == y.value_;`

```
friend constexpr bool operator<(const iterator& x, const iterator& y)
    requires totally_ordered<W>;
```

Effects: Equivalent to: `return x.value_ < y.value_;`

```
friend constexpr bool operator>(const iterator& x, const iterator& y)
    requires totally_ordered<W>;
```

Effects: Equivalent to: `return y < x;`

```
friend constexpr bool operator<=(const iterator& x, const iterator& y)
    requires totally_ordered<W>;
```

Effects: Equivalent to: `return !(y < x);`

```
friend constexpr bool operator>=(const iterator& x, const iterator& y)
    requires totally_ordered<W>;
```

Effects: Equivalent to: `return !(x < y);`

```
friend constexpr auto operator<=>(const iterator& x, const iterator& y)
    requires totally_ordered<W> && three_way_comparable<W>;
```

Effects: Equivalent to: `return x.value_ <=> y.value_;`

```
friend constexpr iterator operator+(iterator i, difference_type n)
    requires advanceable<W>;
```

Effects: Equivalent to:

```
    i += n;
    return i;
```

```
friend constexpr iterator operator+(difference_type n, iterator i)
    requires advanceable<W>;
```

Effects: Equivalent to: `return i + n;`

```
friend constexpr iterator operator-(iterator i, difference_type n)
    requires advanceable<W>;
```

Effects: Equivalent to:

```
    i -= n;
    return i;
```

```
friend constexpr difference_type operator-(const iterator& x, const iterator& y)
    requires advanceable<W>;
```

Effects: Equivalent to:

```
    using D = difference_type;
    if constexpr (is-integer-like<W>) {
        if constexpr (is-signed-integer-like<W>)
            return D(D(x.value_) - D(y.value_));
        else
            return (y.value_ > x.value_)
                ? D(-D(y.value_ - x.value_))
                : D(x.value_ - y.value_);
    } else {
        return x.value_ - y.value_;
    }
```

26.6.4.4 Class `iota_view::sentinel`

[range.iota.sentinel]

```
namespace std::ranges {
    template<weakly_incrementable W, semiregular Bound>
        requires weakly-equality-comparable-with<W, Bound> && copyable<W>
        struct iota_view<W, Bound>::sentinel {
```

```

private:
    Bound bound_ = Bound();    // exposition only

public:
    sentinel() = default;
    constexpr explicit sentinel(Bound bound);

    friend constexpr bool operator==(const iterator& x, const sentinel& y);

    friend constexpr iter_difference_t<W> operator-(const iterator& x, const sentinel& y)
        requires sized_sentinel_for<Bound, W>;
    friend constexpr iter_difference_t<W> operator-(const sentinel& x, const iterator& y)
        requires sized_sentinel_for<Bound, W>;
};

constexpr explicit sentinel(Bound bound);
    Effects: Initializes bound_ with bound.

friend constexpr bool operator==(const iterator& x, const sentinel& y);
    Effects: Equivalent to: return x.value_ == y.bound_;

friend constexpr iter_difference_t<W> operator-(const iterator& x, const sentinel& y)
    requires sized_sentinel_for<Bound, W>;
    Effects: Equivalent to: return x.value_ - y.bound_;

friend constexpr iter_difference_t<W> operator-(const sentinel& x, const iterator& y)
    requires sized_sentinel_for<Bound, W>;
    Effects: Equivalent to: return -(y - x);

```

26.6.5 Repeat view

[range.repeat]

26.6.5.1 Overview

[range.repeat.overview]

`repeat_view` generates a sequence of elements by repeatedly producing the same value.

The name `views::repeat` denotes a customization point object (16.3.3.3.5). Given subexpressions *E* and *F*, the expressions `views::repeat(E)` and `views::repeat(E, F)` are expression-equivalent to `repeat_view(E)` and `repeat_view(E, F)`, respectively.

EXAMPLE

```

for (int i : views::repeat(17, 4))
    cout << i << ' ';
// prints 17 17 17 17

```

26.6.5.2 Class template `repeat_view`

[range.repeat.view]

```

namespace std::ranges {
    template<class T>
        concept integer-like-with-usable-difference-type = // exposition only
            is-signed-integer-like<T> || (is-integer-like<T> && weakly_incrementable<T>);

    template<move_constructible T, semiregular Bound = unreachable_sentinel_t>
        requires (is_object_v<T> && same_as<T, remove_cv_t<T>> &&
            (integer-like-with-usable-difference-type<Bound> ||
            same_as<Bound, unreachable_sentinel_t>))
        class repeat_view : public view_interface<repeat_view<T, Bound>> {
        private:
            // 26.6.5.3, class repeat_view::iterator
            struct iterator;    // exposition only

            movable_box<T> value_;    // exposition only, see 26.7.3
            Bound bound_ = Bound();    // exposition only
        };
    };

```

```

public:
    repeat_view() requires default_initializable<T> = default;

    constexpr explicit repeat_view(const T& value, Bound bound = Bound())
        requires copy_constructible<T>;
    constexpr explicit repeat_view(T&& value, Bound bound = Bound());
    template<class... TArgs, class... BoundArgs>
        requires constructible_from<T, TArgs...> &&
            constructible_from<Bound, BoundArgs...>
    constexpr explicit repeat_view(piecewise_construct_t,
        tuple<TArgs...> value_args, tuple<BoundArgs...> bound_args = tuple<>{});

    constexpr iterator begin() const;
    constexpr iterator end() const requires (!same_as<Bound, unreachable_sentinel_t>);
    constexpr unreachable_sentinel_t end() const noexcept;

    constexpr auto size() const requires (!same_as<Bound, unreachable_sentinel_t>);
};

template<class T, class Bound>
    repeat_view(T, Bound) -> repeat_view<T, Bound>;
}

constexpr explicit repeat_view(const T& value, Bound bound = Bound())
    requires copy_constructible<T>;

    Preconditions: If Bound is not unreachable_sentinel_t, bound ≥ 0.
    Effects: Initializes value_ with value and bound_ with bound.

constexpr explicit repeat_view(T&& value, Bound bound = Bound());

    Preconditions: If Bound is not unreachable_sentinel_t, bound ≥ 0.
    Effects: Initializes value_ with std::move(value) and bound_ with bound.

template<class... TArgs, class... BoundArgs>
    requires constructible_from<T, TArgs...> &&
        constructible_from<Bound, BoundArgs...>
constexpr explicit repeat_view(piecewise_construct_t,
    tuple<TArgs...> value_args, tuple<BoundArgs...> bound_args = tuple<>{});

    Effects: Initializes value_ with make_from_tuple<T>(std::move(value_args)) and initializes
    bound_ with make_from_tuple<Bound>(std::move(bound_args)). The behavior is undefined if Bound
    is not unreachable_sentinel_t and bound_ is negative.

constexpr iterator begin() const;

    Effects: Equivalent to: return iterator(addressof(*value_));

constexpr iterator end() const requires (!same_as<Bound, unreachable_sentinel_t>);

    Effects: Equivalent to: return iterator(addressof(*value_), bound_);

constexpr unreachable_sentinel_t end() const noexcept;

    Effects: Equivalent to: return unreachable_sentinel;

constexpr auto size() const requires (!same_as<Bound, unreachable_sentinel_t>);

    Effects: Equivalent to: return to-unsigned-like(bound_);

```

26.6.5.3 Class repeat_view::iterator

[range.repeat.iterator]

```

namespace std::ranges {
    template<move_constructible T, semiregular Bound>
        requires (is_object_v<T> && same_as<T, remove_cv_t<T>> &&
            (integer_like_with_usable_difference_type<Bound> ||
            same_as<Bound, unreachable_sentinel_t>))
    class repeat_view<T, Bound>::iterator {
    private:

```

```

using index-type =                                // exposition only
    conditional_t<same_as<Bound, unreachable_sentinel_t>, ptrdiff_t, Bound>;
const T* value_ = nullptr;                        // exposition only
index-type current_ = index-type();               // exposition only

constexpr explicit iterator(const T* value, index-type b = index-type()); // exposition only

public:
    using iterator_concept = random_access_iterator_tag;
    using iterator_category = random_access_iterator_tag;
    using value_type = T;
    using difference_type = see below;

    iterator() = default;

    constexpr const T& operator*() const noexcept;

    constexpr iterator& operator++();
    constexpr iterator operator++(int);

    constexpr iterator& operator--();
    constexpr iterator operator--(int);

    constexpr iterator& operator+=(difference_type n);
    constexpr iterator& operator-=(difference_type n);
    constexpr const T& operator[](difference_type n) const noexcept;

    friend constexpr bool operator==(const iterator& x, const iterator& y);
    friend constexpr auto operator<=>(const iterator& x, const iterator& y);

    friend constexpr iterator operator+(iterator i, difference_type n);
    friend constexpr iterator operator+(difference_type n, iterator i);

    friend constexpr iterator operator-(iterator i, difference_type n);
    friend constexpr difference_type operator-(const iterator& x, const iterator& y);
};
}

```

If *is-signed-integer-like*<*index-type*> is true, the member *typedef-name* *difference_type* denotes *index-type*. Otherwise, it denotes *IOTA-DIFF-T(index-type)* (26.6.4.2).

```
constexpr explicit iterator(const T* value, index-type b = index-type());
```

Preconditions: If *Bound* is not *unreachable_sentinel_t*, $b \geq 0$.

Effects: Initializes *value_* with *value* and *current_* with *b*.

```
constexpr const T& operator*() const noexcept;
```

Effects: Equivalent to: `return *value_;`

```
constexpr iterator& operator++();
```

Effects: Equivalent to:

```

++current_;
return *this;

```

```
constexpr iterator operator++(int);
```

Effects: Equivalent to:

```

auto tmp = *this;
+++this;
return tmp;

```

```
constexpr iterator& operator--();
```

Preconditions: If *Bound* is not *unreachable_sentinel_t*, *current_* > 0.

Effects: Equivalent to:

```
--current_;
return *this;
```

```
constexpr iterator operator--(int);
```

Effects: Equivalent to:

```
auto tmp = *this;
--*this;
return tmp;
```

```
constexpr iterator& operator+=(difference_type n);
```

Preconditions: If Bound is not unreachable_sentinel_t, $current\_ + n \geq 0$.

Effects: Equivalent to:

```
current_ += n;
return *this;
```

```
constexpr iterator& operator-=(difference_type n);
```

Preconditions: If Bound is not unreachable_sentinel_t, $current\_ - n \geq 0$.

Effects: Equivalent to:

```
current_ -= n;
return *this;
```

```
constexpr const T& operator[](difference_type n) const noexcept;
```

Effects: Equivalent to: return $*(this + n)$;

```
friend constexpr bool operator==(const iterator& x, const iterator& y);
```

Effects: Equivalent to: return $x.current\_ == y.current\_;$

```
friend constexpr auto operator<=>(const iterator& x, const iterator& y);
```

Effects: Equivalent to: return $x.current\_ <=> y.current\_;$

```
friend constexpr iterator operator+(iterator i, difference_type n);
```

```
friend constexpr iterator operator+(difference_type n, iterator i);
```

Effects: Equivalent to:

```
i += n;
return i;
```

```
friend constexpr iterator operator-(iterator i, difference_type n);
```

Effects: Equivalent to:

```
i -= n;
return i;
```

```
friend constexpr difference_type operator-(const iterator& x, const iterator& y);
```

Effects: Equivalent to:

```
return static_cast<difference_type>(x.current_) - static_cast<difference_type>(y.current_);
```

26.6.6 Istream view

[range.istream]

26.6.6.1 Overview

[range.istream.overview]

basic_istream_view models input_range and reads (using operator>>) successive elements from its corresponding input stream.

The name views::istream<T> denotes a customization point object (16.3.3.3.5). Given a type T and a subexpression E of type U, if U models derived_from<basic_istream<typename U::char_type, typename U::traits_type>>, then the expression views::istream<T>(E) is expression-equivalent to basic_istream_view<T, typename U::char_type, typename U::traits_type>(E); otherwise, views::istream<T>(E) is ill-formed.

EXAMPLE

```
auto ints = istringstream{"0 1 2 3 4"};
ranges::copy(views::istream<int>(ints), ostream_iterator<int>{cout, "-"});
// prints 0-1-2-3-4-
```

26.6.6.2 Class template basic_istream_view

[range.istream.view]

```
namespace std::ranges {
    template<class Val, class CharT, class Traits>
        concept stream-extractable = // exposition only
            requires(basic_istream<CharT, Traits>& is, Val& t) {
                is >> t;
            };

    template<movable Val, class CharT, class Traits = char_traits<CharT>>
        requires default_initializable<Val> &&
            stream-extractable<Val, CharT, Traits>
    class basic_istream_view : public view_interface<basic_istream_view<Val, CharT, Traits>> {
    public:
        constexpr explicit basic_istream_view(basic_istream<CharT, Traits>& stream);

        constexpr auto begin() {
            *stream_ >> value_;
            return iterator{*this};
        }

        constexpr default_sentinel_t end() const noexcept;

    private:
        // 26.6.6.3, class basic_istream_view::iterator
        struct iterator; // exposition only
        basic_istream<CharT, Traits>* stream_; // exposition only
        Val value_ = Val(); // exposition only
    };
}

constexpr explicit basic_istream_view(basic_istream<CharT, Traits>& stream);
    Effects: Initializes stream_ with addressof(stream).

constexpr default_sentinel_t end() const noexcept;
    Effects: Equivalent to: return default_sentinel;
```

26.6.6.3 Class basic_istream_view::iterator

[range.istream.iterator]

```
namespace std::ranges {
    template<movable Val, class CharT, class Traits>
        requires default_initializable<Val> &&
            stream-extractable<Val, CharT, Traits>
    class basic_istream_view<Val, CharT, Traits>::iterator {
    public:
        using iterator_concept = input_iterator_tag;
        using difference_type = ptrdiff_t;
        using value_type = Val;

        constexpr explicit iterator(basic_istream_view& parent) noexcept;

        iterator(const iterator&) = delete;
        iterator(iterator&&) = default;

        iterator& operator=(const iterator&) = delete;
        iterator& operator=(iterator&&) = default;

        iterator& operator++();
        void operator++(int);
```

```

Val& operator*() const;

friend bool operator==(const iterator& x, default_sentinel_t);

private:
    basic_istream_view* parent_;
};
}

constexpr explicit iterator(basic_istream_view& parent) noexcept;
    Effects: Initializes parent_ with addressof(parent).

iterator& operator++();
    Effects: Equivalent to:
        *parent_->stream_ >> parent_->value_;
        return *this;

void operator++(int);
    Effects: Equivalent to ++*this.

Val& operator*() const;
    Effects: Equivalent to: return parent_->value_;

friend bool operator==(const iterator& x, default_sentinel_t);
    Effects: Equivalent to: return !x.parent_->stream_;

```

26.7 Range adaptors

[range.adaptors]

26.7.1 General

[range.adaptors.general]

Subclause 26.7 defines *range adaptors*, which are utilities that transform a range into a view with custom behaviors. These adaptors can be chained to create pipelines of range transformations that evaluate lazily as the resulting view is iterated.

Range adaptors are declared in namespace `std::ranges::views`.

The bitwise OR operator is overloaded for the purpose of creating adaptor chain pipelines. The adaptors also support function call syntax with equivalent semantics.

EXAMPLE

```

vector<int> ints{0,1,2,3,4,5};
auto even = [](int i) { return 0 == i % 2; };
auto square = [](int i) { return i * i; };
for (int i : ints | views::filter(even) | views::transform(square)) {
    cout << i << ' '; // prints 0 4 16
}
assert(ranges::equal(ints | views::filter(even), views::filter(ints, even)));

```

26.7.2 Range adaptor objects

[range.adaptor.object]

A *range adaptor closure object* is a unary function object that accepts a range argument. For a range adaptor closure object *C* and an expression *R* such that `decltype((R))` models **range**, the following expressions are equivalent:

```

C(R)
R | C

```

Given an additional range adaptor closure object *D*, the expression `C | D` produces another range adaptor closure object *E*. *E* is a perfect forwarding call wrapper (22.10.4) with the following properties:

- Its target object is an object *d* of type `decay_t<decltype((D))>` direct-non-list-initialized with *D*.
- It has one bound argument entity, an object *c* of type `decay_t<decltype((C))>` direct-non-list-initialized with *C*.
- Its call pattern is `d(c(arg))`, where *arg* is the argument used in a function call expression of *E*.

The expression `C | D` is well-formed if and only if the initializations of the state entities of `E` are all well-formed. Given an object `t` of type `T`, where

- `t` is a unary function object that accepts a range argument,
- `T` models `derived_from<range_adaptor_closure<T>>`,
- `T` has no other base classes of type `range_adaptor_closure<U>` for any other type `U`, and
- `T` does not model `range`

then the implementation ensures that `t` is a range adaptor closure object.

The template parameter `D` for `range_adaptor_closure` may be an incomplete type. If an expression of type `cv D` is used as an operand to the `|` operator, `D` shall be complete and model `derived_from<range_adaptor_closure<D>>`. The behavior of an expression involving an object of type `cv D` as an operand to the `|` operator is undefined if overload resolution selects a program-defined `operator|` function.

If an expression of type `cv U` is used as an operand to the `|` operator, where `U` has a base class of type `range_adaptor_closure<T>` for some type `T` other than `U`, the behavior is undefined.

The behavior of a program that adds a specialization for `range_adaptor_closure` is undefined.

A *range adaptor object* is a customization point object (16.3.3.3.5) that accepts a `viewable_range` as its first argument and returns a view.

If a range adaptor object accepts only one argument, then it is a range adaptor closure object.

If a range adaptor object `adaptor` accepts more than one argument, then let `range` be an expression such that `decltype((range))` models `viewable_range`, let `args...` be arguments such that `adaptor(range, args...)` is a well-formed expression as specified in the rest of subclause 26.7, and let `BoundArgs` be a pack that denotes `decay_t<decltype((args))>...`. The expression `adaptor(args...)` produces a range adaptor closure object `f` that is a perfect forwarding call wrapper (22.10.4) with the following properties:

- Its target object is a copy of `adaptor`.
- Its bound argument entities `bound_args` consist of objects of types `BoundArgs...` direct-non-list-initialized with `std::forward<decltype((args))>(args)...`, respectively.
- Its call pattern is `adaptor(r, bound_args...)`, where `r` is the argument used in a function call expression of `f`.

The expression `adaptor(args...)` is well-formed if and only if the initialization of the bound argument entities of the result, as specified above, are all well-formed.

26.7.3 Movable wrapper

[`range.move.wrap`]

Many types in this subclause are specified in terms of an exposition-only class template `movable-box`. `movable-box<T>` behaves exactly like `optional<T>` with the following differences:

- `movable-box<T>` constrains its type parameter `T` with `move_constructible<T> && is_object_v<T>`.
- The default constructor of `movable-box<T>` is equivalent to:

```
constexpr movable-box() noexcept(is_nothrow_default_constructible_v<T>)
    requires default_initializable<T>
    : movable-box{in_place} {}
```

- If `copyable<T>` is not modeled, the copy assignment operator is equivalent to:

```
constexpr movable-box& operator=(const movable-box& that)
    noexcept(is_nothrow_copy_constructible_v<T>)
    requires copy_constructible<T> {
    if (this != addressof(that)) {
        if (that) emplace(*that);
        else reset();
    }
    return *this;
}
```

- If `movable<T>` is not modeled, the move assignment operator is equivalent to:

```
constexpr movable-box& operator=(movable-box&& that)
noexcept(is_nothrow_move_constructible_v<T>) {
    if (this != addressof(that)) {
        if (that) emplace(std::move(*that));
        else reset();
    }
    return *this;
}
```

Recommended practice:

- If `copy_constructible<T>` is true, `movable-box<T>` should store only a `T` if either `T` models copyable, or `is_nothrow_move_constructible_v<T>` && `is_nothrow_copy_constructible_v<T>` is true.
- Otherwise, `movable-box<T>` should store only a `T` if either `T` models movable or `is_nothrow_move_constructible_v<T>` is true.

26.7.4 Non-propagating cache

[range.nonprop.cache]

Some types in 26.7 are specified in terms of an exposition-only class template `non-propagating-cache`. `non-propagating-cache<T>` behaves exactly like `optional<T>` with the following differences:

- `non-propagating-cache<T>` constrains its type parameter `T` with `is_object_v<T>`.
- The copy constructor is equivalent to:

```
constexpr non-propagating-cache(const non-propagating-cache&) noexcept {}
```

- The move constructor is equivalent to:

```
constexpr non-propagating-cache(non-propagating-cache&& other) noexcept {
    other.reset();
}
```

- The copy assignment operator is equivalent to:

```
constexpr non-propagating-cache& operator=(const non-propagating-cache& other) noexcept {
    if (addressof(other) != this)
        reset();
    return *this;
}
```

- The move assignment operator is equivalent to:

```
constexpr non-propagating-cache& operator=(non-propagating-cache&& other) noexcept {
    reset();
    other.reset();
    return *this;
}
```

- `non-propagating-cache<T>` has an additional member function template specified as follows:

```
template<class T>
constexpr T& emplace-deref(const T& i);    // exposition only
```

Mandates: The declaration `T t(*i)`; is well-formed for some invented variable `t`.

NOTE 1 If `*i` is a prvalue of type `cv T`, there is no requirement that it is movable (9.4.1).

Effects: Calls `reset()`. Then direct-non-list-initializes the contained value with `*i`.

Postconditions: `*this` contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the initialization of the contained value.

Remarks: If an exception is thrown during the initialization of `T`, `*this` does not contain a value, and the previous value (if any) has been destroyed.

NOTE 2 `non-propagating-cache` enables an input view to temporarily cache values as it is iterated over.

26.7.5 Range adaptor helpers

[range.adaptor.helpers]

```

namespace std::ranges {
    template<class F, class Tuple>
    constexpr auto tuple-transform(F&& f, Tuple&& t) { // exposition only
        return apply([&<class... Ts>(Ts&&... elements) {
            return tuple<invoke_result_t<F&, Ts>...>(invoke(f, std::forward<Ts>(elements))...);
        }, std::forward<Tuple>(t));
    }

    template<class F, class Tuple>
    constexpr void tuple-for-each(F&& f, Tuple&& t) { // exposition only
        apply([&<class... Ts>(Ts&&... elements) {
            (static_cast<void>(invoke(f, std::forward<Ts>(elements))), ...);
        }, std::forward<Tuple>(t));
    }

    template<class T>
    constexpr T& as-lvalue(T&& t) { // exposition only
        return static_cast<T&>(t);
    }
}

```

26.7.6 All view

[range.all]

26.7.6.1 General

[range.all.general]

`views::all` returns a view that includes all elements of its range argument.

The name `views::all` denotes a range adaptor object (26.7.2). Given a subexpression `E`, the expression `views::all(E)` is expression-equivalent to:

- *decay-copy*(`E`) if the decayed type of `E` models `view`.
- Otherwise, `ref_view{E}` if that expression is well-formed.
- Otherwise, `owning_view{E}`.

26.7.6.2 Class template `ref_view`

[range.ref.view]

`ref_view` is a view of the elements of some other range.

```

namespace std::ranges {
    template<range R>
    requires is_object_v<R>
    class ref_view : public view_interface<ref_view<R>> {
    private:
        R* r_; // exposition only

    public:
        template<different-from<ref_view> T>
        requires see below
        constexpr ref_view(T&& t);

        constexpr R& base() const { return *r_; }

        constexpr iterator_t<R> begin() const { return ranges::begin(*r_); }
        constexpr sentinel_t<R> end() const { return ranges::end(*r_); }

        constexpr bool empty() const
            requires requires { ranges::empty(*r_); }
        { return ranges::empty(*r_); }

        constexpr auto size() const requires sized_range<R>
        { return ranges::size(*r_); }

        constexpr auto data() const requires contiguous_range<R>
        { return ranges::data(*r_); }
    };
}

```

```

template<class R>
    ref_view(R&) -> ref_view<R>;
}

template<different-from<ref_view> T>
    requires see below
constexpr ref_view(T&& t);

Effects: Initializes  $r_$  with addressof(static_cast<R&>(std::forward<T>(t))).

Remarks: Let FUN denote the exposition-only functions

    void FUN(R&);
    void FUN(R&&) = delete;

The expression in the requires-clause is equivalent to:

    convertible_to<T, R&> && requires { FUN(declval<T>()); }

```

26.7.6.3 Class template `owning_view`

[range.owning.view]

`owning_view` is a move-only view of the elements of some other range.

```

namespace std::ranges {
    template<range R>
        requires movable<R> && (!is-initializer-list<R>) // see 26.4.5
        class owning_view : public view_interface<owning_view<R>> {
        private:
            R r_ = R(); // exposition only

        public:
            owning_view() requires default_initializable<R> = default;
            constexpr owning_view(R&& t);

            owning_view(owning_view&&) = default;
            owning_view& operator=(owning_view&&) = default;

            constexpr R& base() & noexcept { return r_; }
            constexpr const R& base() const & noexcept { return r_; }
            constexpr R&& base() && noexcept { return std::move(r_); }
            constexpr const R&& base() const && noexcept { return std::move(r_); }

            constexpr iterator_t<R> begin() { return ranges::begin(r_); }
            constexpr sentinel_t<R> end() { return ranges::end(r_); }

            constexpr auto begin() const requires range<const R>
            { return ranges::begin(r_); }
            constexpr auto end() const requires range<const R>
            { return ranges::end(r_); }

            constexpr bool empty() requires requires { ranges::empty(r_); }
            { return ranges::empty(r_); }
            constexpr bool empty() const requires requires { ranges::empty(r_); }
            { return ranges::empty(r_); }

            constexpr auto size() requires sized_range<R>
            { return ranges::size(r_); }
            constexpr auto size() const requires sized_range<const R>
            { return ranges::size(r_); }

            constexpr auto data() requires contiguous_range<R>
            { return ranges::data(r_); }
            constexpr auto data() const requires contiguous_range<const R>
            { return ranges::data(r_); }
        };
}

```

```
constexpr owning_view(R&& t);
```

Effects: Initializes r_+ with `std::move(t)`.

26.7.7 As rvalue view [range.as.rvalue]

26.7.7.1 Overview [range.as.rvalue.overview]

`as_rvalue_view` presents a view of an underlying sequence with the same behavior as the underlying sequence except that its elements are rvalues. Some generic algorithms can be called with an `as_rvalue_view` to replace copying with moving.

The name `views::as_rvalue` denotes a range adaptor object (26.7.2). Let E be an expression and let T be `decltype(E)`. The expression `views::as_rvalue(E)` is expression-equivalent to:

- `views::all(E)` if `same_as<range_rvalue_reference_t<T>, range_reference_t<T>>` is true.
- Otherwise, `as_rvalue_view(E)`.

EXAMPLE

```
vector<string> words = {"the", "quick", "brown", "fox", "ate", "a", "pterodactyl"};
vector<string> new_words;
ranges::copy(words | views::as_rvalue, back_inserter(new_words));
// moves each string from words into new_words
```

26.7.7.2 Class template `as_rvalue_view` [range.as.rvalue.view]

```
namespace std::ranges {
    template<view V>
        requires input_range<V>
        class as_rvalue_view : public view_interface<as_rvalue_view<V>> {
            V base_ = V(); // exposition only

        public:
            as_rvalue_view() requires default_initializable<V> = default;
            constexpr explicit as_rvalue_view(V base);

            constexpr V base() const & requires copy_constructible<V> { return base_; }
            constexpr V base() && { return std::move(base_); }

            constexpr auto begin() requires (!simple_view<V>)
            { return move_iterator(ranges::begin(base_)); }
            constexpr auto begin() const requires range<const V>
            { return move_iterator(ranges::begin(base_)); }

            constexpr auto end() requires (!simple_view<V>) {
                if constexpr (common_range<V>) {
                    return move_iterator(ranges::end(base_));
                } else {
                    return move_sentinel(ranges::end(base_));
                }
            }
            constexpr auto end() const requires range<const V> {
                if constexpr (common_range<const V>) {
                    return move_iterator(ranges::end(base_));
                } else {
                    return move_sentinel(ranges::end(base_));
                }
            }

            constexpr auto size() requires sized_range<V> { return ranges::size(base_); }
            constexpr auto size() const requires sized_range<const V> { return ranges::size(base_); }
        };

    template<class R>
        as_rvalue_view(R&&) -> as_rvalue_view<views::all_t<R>>;
}
```

```
constexpr explicit as_rvalue_view(V base);
```

Effects: Initializes *base_* with `std::move(base)`.

26.7.8 Filter view

[range.filter]

26.7.8.1 Overview

[range.filter.overview]

`filter_view` presents a view of the elements of an underlying sequence that satisfy a predicate.

The name `views::filter` denotes a range adaptor object (26.7.2). Given subexpressions *E* and *P*, the expression `views::filter(E, P)` is expression-equivalent to `filter_view(E, P)`.

EXAMPLE

```
vector<int> is{ 0, 1, 2, 3, 4, 5, 6 };
auto evens = views::filter(is, [](int i) { return 0 == i % 2; });
for (int i : evens)
    cout << i << ' '; // prints 0 2 4 6
```

26.7.8.2 Class template `filter_view`

[range.filter.view]

```
namespace std::ranges {
    template<input_range V, indirect_unary_predicate<iterator_t<V>> Pred>
        requires view<V> && is_object_v<Pred>
    class filter_view : public view_interface<filter_view<V, Pred>> {
    private:
        V base_ = V(); // exposition only
        movable_box<Pred> pred_; // exposition only

        // 26.7.8.3, class filter_view::iterator
        class iterator; // exposition only

        // 26.7.8.4, class filter_view::sentinel
        class sentinel; // exposition only

    public:
        filter_view() requires default_initializable<V> && default_initializable<Pred> = default;
        constexpr explicit filter_view(V base, Pred pred);

        constexpr V base() const & requires copy_constructible<V> { return base_; }
        constexpr V base() && { return std::move(base_); }

        constexpr const Pred& pred() const;

        constexpr iterator begin();
        constexpr auto end() {
            if constexpr (common_range<V>)
                return iterator{*this, ranges::end(base_)};
            else
                return sentinel{*this};
        }
    };

    template<class R, class Pred>
        filter_view(R&&, Pred) -> filter_view<views::all_t<R>, Pred>;
}
```

```
constexpr explicit filter_view(V base, Pred pred);
```

Effects: Initializes *base_* with `std::move(base)` and initializes *pred_* with `std::move(pred)`.

```
constexpr const Pred& pred() const;
```

Effects: Equivalent to: `return *pred_;`

```
constexpr iterator begin();
```

Preconditions: `pred_.has_value()` is true.

Returns: `{*this, ranges::find_if(base_, ref(*pred_))}`.

Remarks: In order to provide the amortized constant time complexity required by the `range` concept when `filter_view` models `forward_range`, this function caches the result within the `filter_view` for use on subsequent calls.

26.7.8.3 Class `filter_view::iterator`

[`range.filter.iterator`]

```
namespace std::ranges {
    template<input_range V, indirect_unary_predicate<iterator_t<V>> Pred>
        requires view<V> && is_object_v<Pred>
    class filter_view<V, Pred>::iterator {
    private:
        iterator_t<V> current_ = iterator_t<V>(); // exposition only
        filter_view* parent_ = nullptr; // exposition only

    public:
        using iterator_concept = see below;
        using iterator_category = see below; // not always present
        using value_type = range_value_t<V>;
        using difference_type = range_difference_t<V>;

        iterator() requires default_initializable<iterator_t<V>> = default;
        constexpr iterator(filter_view& parent, iterator_t<V> current);

        constexpr const iterator_t<V>& base() const & noexcept;
        constexpr iterator_t<V> base() &&;
        constexpr range_reference_t<V> operator*() const;
        constexpr iterator_t<V> operator->() const
            requires has_arrow<iterator_t<V>> && copyable<iterator_t<V>>;

        constexpr iterator& operator++();
        constexpr void operator++(int);
        constexpr iterator operator++(int) requires forward_range<V>;

        constexpr iterator& operator--() requires bidirectional_range<V>;
        constexpr iterator operator--(int) requires bidirectional_range<V>;

        friend constexpr bool operator==(const iterator& x, const iterator& y)
            requires equality_comparable<iterator_t<V>>;

        friend constexpr range_rvalue_reference_t<V> iter_move(const iterator& i)
            noexcept(noexcept(ranges::iter_move(i.current_)));

        friend constexpr void iter_swap(const iterator& x, const iterator& y)
            noexcept(noexcept(ranges::iter_swap(x.current_, y.current_)))
            requires indirectly_swappable<iterator_t<V>>;
    };
}
```

Modification of the element a `filter_view::iterator` denotes is permitted, but results in undefined behavior if the resulting value does not satisfy the filter predicate.

`iterator::iterator_concept` is defined as follows:

- If `V` models `bidirectional_range`, then `iterator_concept` denotes `bidirectional_iterator_tag`.
- Otherwise, if `V` models `forward_range`, then `iterator_concept` denotes `forward_iterator_tag`.
- Otherwise, `iterator_concept` denotes `input_iterator_tag`.

The member `typedef-name` `iterator_category` is defined if and only if `V` models `forward_range`. In that case, `iterator::iterator_category` is defined as follows:

- Let `C` denote the type `iterator_traits<iterator_t<V>>::iterator_category`.
- If `C` models `derived_from<bidirectional_iterator_tag>`, then `iterator_category` denotes `bidirectional_iterator_tag`.
- Otherwise, if `C` models `derived_from<forward_iterator_tag>`, then `iterator_category` denotes `forward_iterator_tag`.

— Otherwise, `iterator_category` denotes `C`.

```
constexpr iterator(filter_view& parent, iterator_t<V> current);
```

Effects: Initializes `current_` with `std::move(current)` and `parent_` with `addressof(parent)`.

```
constexpr const iterator_t<V>& base() const & noexcept;
```

Effects: Equivalent to: `return current_;`

```
constexpr iterator_t<V> base() &&;
```

Effects: Equivalent to: `return std::move(current_);`

```
constexpr range_reference_t<V> operator*() const;
```

Effects: Equivalent to: `return *current_;`

```
constexpr iterator_t<V> operator->() const  
requires has_arrow<iterator_t<V>> && copyable<iterator_t<V>>;
```

Effects: Equivalent to: `return current_;`

```
constexpr iterator& operator++();
```

Effects: Equivalent to:

```
current_ = ranges::find_if(std::move(++current_), ranges::end(parent_>base_),  
                           ref(*parent_>pred_));  
return *this;
```

```
constexpr void operator++(int);
```

Effects: Equivalent to `+++this`.

```
constexpr iterator operator++(int) requires forward_range<V>;
```

Effects: Equivalent to:

```
auto tmp = *this;  
+++this;  
return tmp;
```

```
constexpr iterator& operator--() requires bidirectional_range<V>;
```

Effects: Equivalent to:

```
do  
    --current_;  
while (!invoke(*parent_>pred_, *current_));  
return *this;
```

```
constexpr iterator operator--(int) requires bidirectional_range<V>;
```

Effects: Equivalent to:

```
auto tmp = *this;  
--*this;  
return tmp;
```

```
friend constexpr bool operator==(const iterator& x, const iterator& y)  
requires equality_comparable<iterator_t<V>>;
```

Effects: Equivalent to: `return x.current_ == y.current_;`

```
friend constexpr range_rvalue_reference_t<V> iter_move(const iterator& i)  
noexcept(noexcept(ranges::iter_move(i.current_)));
```

Effects: Equivalent to: `return ranges::iter_move(i.current_);`

```
friend constexpr void iter_swap(const iterator& x, const iterator& y)  
noexcept(noexcept(ranges::iter_swap(x.current_, y.current_)))  
requires indirectly_swappable<iterator_t<V>>;
```

Effects: Equivalent to `ranges::iter_swap(x.current_, y.current_)`.

26.7.8.4 Class `filter_view::sentinel`**[range.filter.sentinel]**

```

namespace std::ranges {
    template<input_range V, indirect_unary_predicate<iterator_t<V>> Pred>
        requires view<V> && is_object_v<Pred>
    class filter_view<V, Pred>::sentinel {
    private:
        sentinel_t<V> end_ = sentinel_t<V>();           // exposition only

    public:
        sentinel() = default;
        constexpr explicit sentinel(filter_view& parent);

        constexpr sentinel_t<V> base() const;

        friend constexpr bool operator==(const iterator& x, const sentinel& y);
    };
}

constexpr explicit sentinel(filter_view& parent);
    Effects: Initializes end_ with ranges::end(parent.base_).

constexpr sentinel_t<V> base() const;
    Effects: Equivalent to: return end_;

friend constexpr bool operator==(const iterator& x, const sentinel& y);
    Effects: Equivalent to: return x.current_ == y.end_;

```

26.7.9 Transform view**[range.transform]****26.7.9.1 Overview****[range.transform.overview]**

`transform_view` presents a view of an underlying sequence after applying a transformation function to each element.

The name `views::transform` denotes a range adaptor object (26.7.2). Given subexpressions *E* and *F*, the expression `views::transform(E, F)` is expression-equivalent to `transform_view(E, F)`.

EXAMPLE

```

vector<int> is{ 0, 1, 2, 3, 4 };
auto squares = views::transform(is, [](int i) { return i * i; });
for (int i : squares)
    cout << i << ' '; // prints 0 1 4 9 16

```

26.7.9.2 Class template `transform_view`**[range.transform.view]**

```

namespace std::ranges {
    template<input_range V, move_constructible F>
        requires view<V> && is_object_v<F> &&
            regular_invocable<F&, range_reference_t<V>> &&
            can_reference<invoke_result_t<F&, range_reference_t<V>>>
    class transform_view : public view_interface<transform_view<V, F>> {
    private:
        // 26.7.9.3, class template transform_view::iterator
        template<bool> struct iterator;           // exposition only

        // 26.7.9.4, class template transform_view::sentinel
        template<bool> struct sentinel;           // exposition only

        V base_ = V();                           // exposition only
        movable_box<F> fun_;                       // exposition only

    public:
        transform_view() requires default_initializable<V> && default_initializable<F> = default;
        constexpr explicit transform_view(V base, F fun);
    };
}

```

```

constexpr V base() const & requires copy_constructible<V> { return base_; }
constexpr V base() && { return std::move(base_); }

constexpr iterator<false> begin();
constexpr iterator<true> begin() const
    requires range<const V> &&
        regular_invocable<const F&, range_reference_t<const V>>;

constexpr sentinel<false> end();
constexpr iterator<false> end() requires common_range<V>;
constexpr sentinel<true> end() const
    requires range<const V> &&
        regular_invocable<const F&, range_reference_t<const V>>;
constexpr iterator<true> end() const
    requires common_range<const V> &&
        regular_invocable<const F&, range_reference_t<const V>>;

constexpr auto size() requires sized_range<V> { return ranges::size(base_); }
constexpr auto size() const requires sized_range<const V>
{ return ranges::size(base_); }
};

template<class R, class F>
    transform_view(R&&, F) -> transform_view<views::all_t<R>, F>;
}

constexpr explicit transform_view(V base, F fun);
    Effects: Initializes base_ with std::move(base) and fun_ with std::move(fun).

constexpr iterator<false> begin();
    Effects: Equivalent to:
        return iterator<false>{*this, ranges::begin(base_)};

constexpr iterator<true> begin() const
    requires range<const V> &&
        regular_invocable<const F&, range_reference_t<const V>>;
    Effects: Equivalent to:
        return iterator<true>{*this, ranges::begin(base_)};

constexpr sentinel<false> end();
    Effects: Equivalent to:
        return sentinel<false>{ranges::end(base_)};

constexpr iterator<false> end() requires common_range<V>;
    Effects: Equivalent to:
        return iterator<false>{*this, ranges::end(base_)};

constexpr sentinel<true> end() const
    requires range<const V> &&
        regular_invocable<const F&, range_reference_t<const V>>;
    Effects: Equivalent to:
        return sentinel<true>{ranges::end(base_)};

constexpr iterator<true> end() const
    requires common_range<const V> &&
        regular_invocable<const F&, range_reference_t<const V>>;
    Effects: Equivalent to:
        return iterator<true>{*this, ranges::end(base_)};

```

26.7.9.3 Class template transform_view::iterator

[range.transform.iterator]

```

namespace std::ranges {
    template<input_range V, move_constructible F>
        requires view<V> && is_object_v<F> &&
            regular_invocable<F&, range_reference_t<V>> &&
            can_reference<invoke_result_t<F&, range_reference_t<V>>>
    template<bool Const>
    class transform_view<V, F>::iterator {
    private:
        using Parent = maybe_const<Const, transform_view>;           // exposition only
        using Base = maybe_const<Const, V>;                         // exposition only
        iterator_t<Base> current_ = iterator_t<Base>();             // exposition only
        Parent* parent_ = nullptr;                                  // exposition only

    public:
        using iterator_concept = see below;
        using iterator_category = see below;                        // not always present
        using value_type =

Effects: Equivalent to: return y.end_ - x.current_;
```

26.7.10 Take view [range.take]

26.7.10.1 Overview [range.take.overview]

`take_view` produces a view of the first N elements from another view, or all the elements if the adapted view contains fewer than N .

The name `views::take` denotes a range adaptor object (26.7.2). Let E and F be expressions, let T be `remove_cvref_t<decltype((E))>`, and let D be `range_difference_t<decltype((E))>`. If `decltype((F))` does not model `convertible_to<D>`, `views::take(E, F)` is ill-formed. Otherwise, the expression `views::take(E, F)` is expression-equivalent to:

- If T is a specialization of `empty_view` (26.6.2.2), then `((void)F, decay-copy(E))`, except that the evaluations of E and F are indeterminately sequenced.
- Otherwise, if T models `random_access_range` and `sized_range` and is a specialization of `span` (24.7.2.2), `basic_string_view` (23.3), or `subrange` (26.5.4), then `U(ranges::begin(E), ranges::begin(E) + std::min<D>(ranges::distance(E), F))`, except that E is evaluated only once, where U is a type determined as follows:
 - if T is a specialization of `span`, then U is `span<typename T::element_type>`;
 - otherwise, if T is a specialization of `basic_string_view`, then U is T ;
 - otherwise, T is a specialization of `subrange`, and U is `subrange<iterator_t<T>>`;
- otherwise, if T is a specialization of `iota_view` (26.6.4.2) that models `random_access_range` and `sized_range`, then `iota_view(*ranges::begin(E), *(ranges::begin(E) + std::min<D>(ranges::distance(E), F)))`, except that E is evaluated only once.
- Otherwise, if T is a specialization of `repeat_view` (26.6.5.2):
 - if T models `sized_range`, then

```
views::repeat(*E.value_, std::min<D>(ranges::distance(E), F))
```

 except that E is evaluated only once;
 - otherwise, `views::repeat(*E.value_, static_cast<D>(F))`.
- Otherwise, `take_view(E, F)`.

EXAMPLE

```
vector<int> is{0,1,2,3,4,5,6,7,8,9};
for (int i : is | views::take(5))
  cout << i << ' '; // prints 0 1 2 3 4
```

26.7.10.2 Class template `take_view` [range.take.view]

```
namespace std::ranges {
  template<view V>
  class take_view : public view_interface<take_view<V>> {
  private:
    V base_ = V(); // exposition only
    range_difference_t<V> count_ = 0; // exposition only

    // 26.7.10.3, class template take_view::sentinel
    template<bool> class sentinel; // exposition only

  public:
    take_view() requires default_initializable<V> = default;
    constexpr explicit take_view(V base, range_difference_t<V> count);

    constexpr V base() const & requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }
```

```

constexpr auto begin() requires (!simple-view<V>) {
    if constexpr (sized_range<V>) {
        if constexpr (random_access_range<V>) {
            return ranges::begin(base_);
        } else {
            auto sz = range_difference_t<V>(size());
            return counted_iterator(ranges::begin(base_), sz);
        }
    } else if constexpr (sized_sentinel_for<sentinel_t<V>, iterator_t<V>>) {
        auto it = ranges::begin(base_);
        auto sz = std::min(count_, ranges::end(base_) - it);
        return counted_iterator(std::move(it), sz);
    } else {
        return counted_iterator(ranges::begin(base_), count_);
    }
}

constexpr auto begin() const requires range<const V> {
    if constexpr (sized_range<const V>) {
        if constexpr (random_access_range<const V>) {
            return ranges::begin(base_);
        } else {
            auto sz = range_difference_t<const V>(size());
            return counted_iterator(ranges::begin(base_), sz);
        }
    } else if constexpr (sized_sentinel_for<sentinel_t<const V>, iterator_t<const V>>) {
        auto it = ranges::begin(base_);
        auto sz = std::min(count_, ranges::end(base_) - it);
        return counted_iterator(std::move(it), sz);
    } else {
        return counted_iterator(ranges::begin(base_), count_);
    }
}

constexpr auto end() requires (!simple-view<V>) {
    if constexpr (sized_range<V>) {
        if constexpr (random_access_range<V>)
            return ranges::begin(base_) + range_difference_t<V>(size());
        else
            return default_sentinel;
    } else if constexpr (sized_sentinel_for<sentinel_t<V>, iterator_t<V>>) {
        return default_sentinel;
    } else {
        return sentinel<false>{ranges::end(base_)};
    }
}

constexpr auto end() const requires range<const V> {
    if constexpr (sized_range<const V>) {
        if constexpr (random_access_range<const V>)
            return ranges::begin(base_) + range_difference_t<const V>(size());
        else
            return default_sentinel;
    } else if constexpr (sized_sentinel_for<sentinel_t<const V>, iterator_t<const V>>) {
        return default_sentinel;
    } else {
        return sentinel<true>{ranges::end(base_)};
    }
}

constexpr auto size() requires sized_range<V> {
    auto n = ranges::size(base_);
    return ranges::min(n, static_cast<decltype(n)>(count_));
}

```

```
constexpr auto size() const requires sized_range<const V> {
    auto n = ranges::size(base_);
    return ranges::min(n, static_cast<decltype(n)>(count_));
}
};
```

```
template<class R>
    take_view(R&&, range_difference_t<R>)
        -> take_view<views::all_t<R>>;
}
```

```
constexpr explicit take_view(V base, range_difference_t<V> count);
```

Preconditions: `count >= 0` is true.

Effects: Initializes `base_` with `std::move(base)` and `count_` with `count`.

26.7.10.3 Class template `take_view::sentinel`

[range.take.sentinel]

```
namespace std::ranges {
    template<view V>
    template<bool Const>
    class take_view<V>::sentinel {
    private:
        using Base = maybe_const<Const, V>; // exposition only
        template<bool OtherConst>
        using CI = counted_iterator<iterator_t<maybe_const<OtherConst, V>>>; // exposition only
        sentinel_t<Base> end_ = sentinel_t<Base>(); // exposition only

    public:
        sentinel() = default;
        constexpr explicit sentinel(sentinel_t<Base> end);
        constexpr sentinel(sentinel_t<!Const> s)
            requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;

        constexpr sentinel_t<Base> base() const;

        friend constexpr bool operator==(const CI<Const>& y, const sentinel& x);

        template<bool OtherConst = !Const>
        requires sentinel_for<sentinel_t<Base>, iterator_t<maybe_const<OtherConst, V>>>
        friend constexpr bool operator==(const CI<OtherConst>& y, const sentinel& x);
    };
}
```

```
constexpr explicit sentinel(sentinel_t<Base> end);
```

Effects: Initializes `end_` with `end`.

```
constexpr sentinel(sentinel_t<!Const> s)
    requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
```

Effects: Initializes `end_` with `std::move(s.end_)`.

```
constexpr sentinel_t<Base> base() const;
```

Effects: Equivalent to: `return end_;`

```
friend constexpr bool operator==(const CI<Const>& y, const sentinel& x);
```

```
template<bool OtherConst = !Const>
    requires sentinel_for<sentinel_t<Base>, iterator_t<maybe_const<OtherConst, V>>>
    friend constexpr bool operator==(const CI<OtherConst>& y, const sentinel& x);
```

Effects: Equivalent to: `return y.count() == 0 || y.base() == x.end_;`

26.7.11 Take while view**[range.take.while]****26.7.11.1 Overview****[range.take.while.overview]**

Given a unary predicate `pred` and a view `r`, `take_while_view` produces a view of the range `[ranges::begin(r), ranges::find_if_not(r, pred))`.

The name `views::take_while` denotes a range adaptor object (26.7.2). Given subexpressions `E` and `F`, the expression `views::take_while(E, F)` is expression-equivalent to `take_while_view(E, F)`.

EXAMPLE

```
auto input = istream{"0 1 2 3 4 5 6 7 8 9"};
auto small = [](const auto x) noexcept { return x < 5; };
auto small_ints = views::istream<int>(input) | views::take_while(small);
for (const auto i : small_ints) {
    cout << i << ' ';
}
// prints 0 1 2 3 4

auto i = 0;
input >> i;
cout << i;
// prints 6
```

26.7.11.2 Class template take_while_view**[range.take.while.view]**

```
namespace std::ranges {
    template<view V, class Pred>
        requires input_range<V> && is_object_v<Pred> &&
            indirect_unary_predicate<const Pred, iterator_t<V>>
    class take_while_view : public view_interface<take_while_view<V, Pred>> {
        // 26.7.11.3, class template take_while_view::sentinel
        template<bool> class sentinel;

        V base_ = V();
        movable_box<Pred> pred_;

    public:
        take_while_view() requires default_initializable<V> && default_initializable<Pred> = default;
        constexpr explicit take_while_view(V base, Pred pred);

        constexpr V base() const & requires copy_constructible<V> { return base_; }
        constexpr V base() && { return std::move(base_); }

        constexpr const Pred& pred() const;

        constexpr auto begin() requires (!simple_view<V>)
        { return ranges::begin(base_); }

        constexpr auto begin() const
            requires range<const V> &&
            indirect_unary_predicate<const Pred, iterator_t<const V>>
        { return ranges::begin(base_); }

        constexpr auto end() requires (!simple_view<V>)
        { return sentinel<false>(ranges::end(base_), addressof(*pred_)); }

        constexpr auto end() const
            requires range<const V> &&
            indirect_unary_predicate<const Pred, iterator_t<const V>>
        { return sentinel<true>(ranges::end(base_), addressof(*pred_)); }
    };

    template<class R, class Pred>
        take_while_view(R&&, Pred) -> take_while_view<views::all_t<R>, Pred>;
}

constexpr explicit take_while_view(V base, Pred pred);
```

Effects: Initializes `base_` with `std::move(base)` and `pred_` with `std::move(pred)`.

```
constexpr const Pred& pred() const;
```

Effects: Equivalent to: return **pred_*;

26.7.11.3 Class template `take_while_view::sentinel`

[range.take.while.sentinel]

```
namespace std::ranges {
    template<view V, class Pred>
        requires input_range<V> && is_object_v<Pred> &&
            indirect_unary_predicate<const Pred, iterator_t<V>>
        template<bool Const>
        class take_while_view<V, Pred>::sentinel {
            using Base = maybe_const<Const, V>;                                // exposition only

            sentinel_t<Base> end_ = sentinel_t<Base>();                        // exposition only
            const Pred* pred_ = nullptr;                                       // exposition only

        public:
            sentinel() = default;
            constexpr explicit sentinel(sentinel_t<Base> end, const Pred* pred);
            constexpr sentinel(sentinel_t<Const> s)
                requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;

            constexpr sentinel_t<Base> base() const { return end_; }

            friend constexpr bool operator==(const iterator_t<Base>& x, const sentinel& y);

            template<bool OtherConst = !Const>
                requires sentinel_for<sentinel_t<Base>, iterator_t<maybe_const<OtherConst, V>>>
            friend constexpr bool operator==(const iterator_t<maybe_const<OtherConst, V>>& x,
                const sentinel& y);
        };
}
```

```
constexpr explicit sentinel(sentinel_t<Base> end, const Pred* pred);
```

Effects: Initializes *end_* with *end* and *pred_* with *pred*.

```
constexpr sentinel(sentinel_t<Const> s)
    requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
```

Effects: Initializes *end_* with `std::move(s.end_)` and *pred_* with *s.pred_*.

```
friend constexpr bool operator==(const iterator_t<Base>& x, const sentinel& y);
```

```
template<bool OtherConst = !Const>
    requires sentinel_for<sentinel_t<Base>, iterator_t<maybe_const<OtherConst, V>>>
friend constexpr bool operator==(const iterator_t<maybe_const<OtherConst, V>>& x,
    const sentinel& y);
```

Effects: Equivalent to: return *y.end_ == x || !invoke(*y.pred_, *x)*;

26.7.12 Drop view

[range.drop]

26.7.12.1 Overview

[range.drop.overview]

`drop_view` produces a view excluding the first *N* elements from another view, or an empty range if the adapted view contains fewer than *N* elements.

The name `views::drop` denotes a range adaptor object (26.7.2). Let *E* and *F* be expressions, let *T* be `remove_cvref_t<decltype((E))>`, and let *D* be `range_difference_t<decltype((E))>`. If `decltype((F))` does not model `convertible_to<D>`, `views::drop(E, F)` is ill-formed. Otherwise, the expression `views::drop(E, F)` is expression-equivalent to:

- If *T* is a specialization of `empty_view` (26.6.2.2), then `((void)F, decay-copy(E))`, except that the evaluations of *E* and *F* are indeterminately sequenced.
- Otherwise, if *T* models `random_access_range` and `sized_range` and is
 - a specialization of `span` (24.7.2.2),

- a specialization of `basic_string_view` (23.3),
- a specialization of `iota_view` (26.6.4.2), or
- a specialization of `subrange` (26.5.4) where `T::StoreSize` is false,

then `U(ranges::begin(E) + std::min<D>(ranges::distance(E), F), ranges::end(E))`, except that `E` is evaluated only once, where `U` is `span<typename T::element_type>` if `T` is a specialization of `span` and `T` otherwise.

- Otherwise, if `T` is a specialization of `subrange` (26.5.4) that models `random_access_range` and `sized_range`, then `T(ranges::begin(E) + std::min<D>(ranges::distance(E), F), ranges::end(E), to-unsigned-like(ranges::distance(E) - std::min<D>(ranges::distance(E), F)))`, except that `E` and `F` are each evaluated only once.
- Otherwise, if `T` is a specialization of `repeat_view` (26.6.5.2):
 - if `T` models `sized_range`, then

```
views::repeat(*E.value_, ranges::distance(E) - std::min<D>(ranges::distance(E), F))
```

 except that `E` is evaluated only once;
 - otherwise, `((void)F, decay-copy(E))`, except that the evaluations of `E` and `F` are indeterminately sequenced.
- Otherwise, `drop_view(E, F)`.

EXAMPLE

```
auto ints = views::iota(0) | views::take(10);
for (auto i : ints | views::drop(5)) {
    cout << i << ' ';
} // prints 5 6 7 8 9
```

26.7.12.2 Class template `drop_view`

[range.drop.view]

```
namespace std::ranges {
    template<view V>
    class drop_view : public view_interface<drop_view<V>> {
    public:
        drop_view() requires default_initializable<V> = default;
        constexpr explicit drop_view(V base, range_difference_t<V> count);

        constexpr V base() const & requires copy_constructible<V> { return base_; }
        constexpr V base() && { return std::move(base_); }

        constexpr auto begin()
            requires (!simple-view<V> &&
                      random_access_range<const V> && sized_range<const V>);
        constexpr auto begin() const
            requires random_access_range<const V> && sized_range<const V>;

        constexpr auto end() requires (!simple-view<V>)
        { return ranges::end(base_); }

        constexpr auto end() const requires range<const V>
        { return ranges::end(base_); }

        constexpr auto size() requires sized_range<V> {
            const auto s = ranges::size(base_);
            const auto c = static_cast<decltype(s)>(count_);
            return s < c ? 0 : s - c;
        }

        constexpr auto size() const requires sized_range<const V> {
            const auto s = ranges::size(base_);
            const auto c = static_cast<decltype(s)>(count_);
            return s < c ? 0 : s - c;
        }
    }
}
```

```

private:
    V base_ = V(); // exposition only
    range_difference_t<V> count_ = 0; // exposition only
};

template<class R>
    drop_view(R&&, range_difference_t<R>) -> drop_view<views::all_t<R>>;
}

constexpr explicit drop_view(V base, range_difference_t<V> count);

```

Preconditions: `count >= 0` is true.

Effects: Initializes `base_` with `std::move(base)` and `count_` with `count`.

```

constexpr auto begin()
    requires (!simple_view<V> &&
        random_access_range<const V> && sized_range<const V>));
constexpr auto begin() const
    requires random_access_range<const V> && sized_range<const V>;

```

Returns: `ranges::next(ranges::begin(base_), count_, ranges::end(base_))`.

Remarks: In order to provide the amortized constant-time complexity required by the `range` concept when `drop_view` models `forward_range`, the first overload caches the result within the `drop_view` for use on subsequent calls.

NOTE Without this, applying a `reverse_view` over a `drop_view` would have quadratic iteration complexity.

26.7.13 Drop while view

[range.drop.while]

26.7.13.1 Overview

[range.drop.while.overview]

Given a unary predicate `pred` and a view `r`, `drop_while_view` produces a view of the range `[ranges::find_if_not(r, pred), ranges::end(r))`.

The name `views::drop_while` denotes a range adaptor object (26.7.2). Given subexpressions `E` and `F`, the expression `views::drop_while(E, F)` is expression equivalent to `drop_while_view(E, F)`.

EXAMPLE

```

constexpr auto source = " \t \t \t hello there"sv;
auto is_invisible = [](const auto x) { return x == ' ' || x == '\t'; };
auto skip_ws = views::drop_while(source, is_invisible);
for (auto c : skip_ws) {
    cout << c; // prints hello there with no leading space
}

```

26.7.13.2 Class template `drop_while_view`

[range.drop.while.view]

```

namespace std::ranges {
    template<view V, class Pred>
        requires input_range<V> && is_object_v<Pred> &&
            indirect_unary_predicate<const Pred, iterator_t<V>>
        class drop_while_view : public view_interface<drop_while_view<V, Pred>> {
        public:
            drop_while_view() requires default_initializable<V> && default_initializable<Pred> = default;
            constexpr explicit drop_while_view(V base, Pred pred);

            constexpr V base() const & requires copy_constructible<V> { return base_; }
            constexpr V base() && { return std::move(base_); }

            constexpr const Pred& pred() const;

            constexpr auto begin();

            constexpr auto end() { return ranges::end(base_); }

        private:
            V base_ = V(); // exposition only

```

```

    movable_box<Pred> pred_;                                // exposition only
};

template<class R, class Pred>
    drop_while_view(R&&, Pred) -> drop_while_view<views::all_t<R>, Pred>;
}

constexpr explicit drop_while_view(V base, Pred pred);
    Effects: Initializes base_ with std::move(base) and pred_ with std::move(pred).

constexpr const Pred& pred() const;
    Effects: Equivalent to: return *pred_;

constexpr auto begin();
    Preconditions: pred_.has_value() is true.
    Returns: ranges::find_if_not(base_, cref(*pred_)).
    Remarks: In order to provide the amortized constant-time complexity required by the range concept
    when drop_while_view models forward_range, the first call caches the result within the drop_while_
    view for use on subsequent calls.
    NOTE Without this, applying a reverse_view over a drop_while_view would have quadratic iteration com-
    plexity.

```

26.7.14 Join view

[range.join]

26.7.14.1 Overview

[range.join.overview]

`join_view` flattens a view of ranges into a view.

The name `views::join` denotes a range adaptor object (26.7.2). Given a subexpression *E*, the expression `views::join(E)` is expression-equivalent to `join_view<views::all_t<decltype(E)>>>{E}`.

EXAMPLE

```

vector<string> ss{"hello", " ", "world", "!"};
for (char ch : ss | views::join)
    cout << ch;                                // prints hello world!

```

26.7.14.2 Class template `join_view`

[range.join.view]

```

namespace std::ranges {
    template<input_range V>
        requires view<V> && input_range<range_reference_t<V>>
        class join_view : public view_interface<join_view<V>> {
        private:
            using InnerRng = range_reference_t<V>;                                // exposition only

            // 26.7.14.3, class template join_view::iterator
            template<bool Const>
                struct iterator;                                                // exposition only

            // 26.7.14.4, class template join_view::sentinel
            template<bool Const>
                struct sentinel;                                                // exposition only

            V base_ = V();                                                        // exposition only

            non_propagating_cache<iterator_t<V>> outer_;                        // exposition only, present only
                                                                                   // when !forward_range<V>
            non_propagating_cache<remove_cv_t<InnerRng>> inner_;                 // exposition only, present only
                                                                                   // if is_reference_v<InnerRng> is false

        public:
            join_view() requires default_initializable<V> = default;
            constexpr explicit join_view(V base);

```

```

constexpr V base() const & requires copy_constructible<V> { return base_; }
constexpr V base() && { return std::move(base_); }

constexpr auto begin() {
    if constexpr (forward_range<V>) {
        constexpr bool use_const = simple-view<V> &&
                                   is_reference_v<InnerRng>;
        return iterator<use_const>{*this, ranges::begin(base_)};
    } else {
        outer_ = ranges::begin(base_);
        return iterator<false>{*this};
    }
}

constexpr auto begin() const
    requires forward_range<const V> &&
             is_reference_v<range_reference_t<const V>> &&
             input_range<range_reference_t<const V>>
{ return iterator<true>{*this, ranges::begin(base_)}; }

constexpr auto end() {
    if constexpr (forward_range<V> &&
                 is_reference_v<InnerRng> && forward_range<InnerRng> &&
                 common_range<V> && common_range<InnerRng>)
        return iterator<simple-view<V>>{*this, ranges::end(base_)};
    else
        return sentinel<simple-view<V>>{*this};
}

constexpr auto end() const
    requires forward_range<const V> &&
             is_reference_v<range_reference_t<const V>> &&
             input_range<range_reference_t<const V>> {
    if constexpr (forward_range<range_reference_t<const V>> &&
                 common_range<const V> &&
                 common_range<range_reference_t<const V>>)
        return iterator<true>{*this, ranges::end(base_)};
    else
        return sentinel<true>{*this};
}
};

template<class R>
    explicit join_view(R&&) -> join_view<views::all_t<R>>;
}

constexpr explicit join_view(V base);
Effects: Initializes base_ with std::move(base).

```

26.7.14.3 Class template `join_view::iterator`

[range.join.iterator]

```

namespace std::ranges {
    template<input_range V>
        requires view<V> && input_range<range_reference_t<V>>
        template<bool Const>
        struct join_view<V>::iterator {
        private:
            using Parent    = maybe-const<Const, join_view>;           // exposition only
            using Base      = maybe-const<Const, V>;                  // exposition only
            using OuterIter = iterator_t<Base>;                        // exposition only
            using InnerIter = iterator_t<range_reference_t<Base>>;      // exposition only

            static constexpr bool ref-is-glvalue =                     // exposition only
                is_reference_v<range_reference_t<Base>>;
        };
    };
}

```

```

    OuterIter outer_ = OuterIter(); // exposition only, present only
                                     // if Base models forward_range
    optional<InnerIter> inner_; // exposition only
    Parent* parent_ = nullptr; // exposition only

    constexpr void satisfy(); // exposition only

    constexpr OuterIter& outer(); // exposition only
    constexpr const OuterIter& outer() const; // exposition only

    constexpr iterator(Parent& parent, OuterIter outer)
        requires forward_range<Base>; // exposition only
    constexpr explicit iterator(Parent& parent)
        requires (!forward_range<Base>); // exposition only

public:
    using iterator_concept = see below;
    using iterator_category = see below; // not always present
    using value_type = range_value_t<range_reference_t<Base>>;
    using difference_type = see below;

    iterator() = default;
    constexpr iterator(iterator<!Const> i)
        requires Const &&
            convertible_to<iterator_t<V>, OuterIter> &&
            convertible_to<iterator_t<InnerRng>, InnerIter>;

    constexpr decltype(auto) operator*() const { return **inner_; }

    constexpr InnerIter operator->() const
        requires has_arrow<InnerIter> && copyable<InnerIter>;

    constexpr iterator& operator++();
    constexpr void operator++(int);
    constexpr iterator operator++(int)
        requires ref-is-glvalue && forward_range<Base> &&
            forward_range<range_reference_t<Base>>;

    constexpr iterator& operator--()
        requires ref-is-glvalue && bidirectional_range<Base> &&
            bidirectional_range<range_reference_t<Base>> &&
            common_range<range_reference_t<Base>>;

    constexpr iterator operator--(int)
        requires ref-is-glvalue && bidirectional_range<Base> &&
            bidirectional_range<range_reference_t<Base>> &&
            common_range<range_reference_t<Base>>;

    friend constexpr bool operator==(const iterator& x, const iterator& y)
        requires ref-is-glvalue && forward_range<Base> &&
            equality_comparable<iterator_t<range_reference_t<Base>>>;

    friend constexpr decltype(auto) iter_move(const iterator& i)
        noexcept(noexcept(ranges::iter_move(*i.inner_))) {
        return ranges::iter_move(*i.inner_);
    }

    friend constexpr void iter_swap(const iterator& x, const iterator& y)
        noexcept(noexcept(ranges::iter_swap(*x.inner_, *y.inner_)))
        requires indirectly_swappable<InnerIter>;
};
}

iterator::iterator_concept is defined as follows:

```

- If *ref-is-glvalue* is true, *Base* models *bidirectional_range*, and *range_reference_t<Base>* models both *bidirectional_range* and *common_range*, then *iterator_concept* denotes *bidirectional_iterator_tag*.
- Otherwise, if *ref-is-glvalue* is true and *Base* and *range_reference_t<Base>* each model *forward_range*, then *iterator_concept* denotes *forward_iterator_tag*.
- Otherwise, *iterator_concept* denotes *input_iterator_tag*.

The member *typedef-name* *iterator_category* is defined if and only if *ref-is-glvalue* is true, *Base* models *forward_range*, and *range_reference_t<Base>* models *forward_range*. In that case, *iterator::iterator_category* is defined as follows:

- Let *OUTERC* denote *iterator_traits<iterator_t<Base>>::iterator_category*, and let *INNERC* denote *iterator_traits<iterator_t<range_reference_t<Base>>>::iterator_category*.
- If *OUTERC* and *INNERC* each model *derived_from<bidirectional_iterator_tag>* and *range_reference_t<Base>* models *common_range*, *iterator_category* denotes *bidirectional_iterator_tag*.
- Otherwise, if *OUTERC* and *INNERC* each model *derived_from<forward_iterator_tag>*, *iterator_category* denotes *forward_iterator_tag*.
- Otherwise, *iterator_category* denotes *input_iterator_tag*.

iterator::difference_type denotes the type:

```
common_type_t<
    range_difference_t<Base>,
    range_difference_t<range_reference_t<Base>>>
```

join_view iterators use the *satisfy* function to skip over empty inner ranges.

```
constexpr OuterIter& outer();
constexpr const OuterIter& outer() const;
```

Returns: *outer_* if *Base* models *forward_range*; otherwise, **parent_->outer_*.

```
constexpr void satisfy();
```

Effects: Equivalent to:

```
auto update_inner = [this](const iterator_t<Base>& x) -> auto&& {
    if constexpr (ref-is-glvalue) // *x is a reference
        return *x;
    else
        return parent_->inner_.emplace-deref(x);
};

for (; outer() != ranges::end(parent_->base_); ++outer()) {
    auto&& inner = update_inner(outer());
    inner_ = ranges::begin(inner);
    if (*inner_ != ranges::end(inner))
        return;
}
if constexpr (ref-is-glvalue)
    inner_.reset();
```

```
constexpr iterator(Parent& parent, OuterIter outer)
requires forward_range<Base>;
```

Effects: Initializes *outer_* with *std::move(outer)* and *parent_* with *addressof(parent)*; then calls *satisfy()*.

```
constexpr explicit iterator(Parent& parent)
requires (!forward_range<Base>;
```

Effects: Initializes *parent_* with *addressof(parent)*; then calls *satisfy()*.

```
constexpr iterator(iterator<!Const> i)
requires Const &&
    convertible_to<iterator_t<V>, OuterIter> &&
```

```
convertible_to<iterator_t<InnerRng>, InnerIter>;
```

Effects: Initializes *outer_* with `std::move(i.outer_)`, *inner_* with `std::move(i.inner_)`, and *parent_* with `i.parent_`.

NOTE *Const* can only be *true* when *Base* models *forward_range*.

```
constexpr InnerIter operator->() const
requires has_arrow<InnerIter> && copyable<InnerIter>;
```

Effects: Equivalent to: `return *inner_;`

```
constexpr iterator& operator++();
```

Let *inner-range* be:

- If *ref-is-glvalue* is *true*, `*outer_()`.
- Otherwise, `*parent_->inner_`.

Effects: Equivalent to:

```
if (++*inner_ == ranges::end(as_lvalue(inner-range))) {
    ++*outer_();
    satisfy();
}
return *this;
```

```
constexpr void operator++(int);
```

Effects: Equivalent to: `++*this`.

```
constexpr iterator operator++(int)
requires ref_is_glvalue && forward_range<Base> &&
         forward_range<range_reference_t<Base>>;
```

Effects: Equivalent to:

```
auto tmp = *this;
++*this;
return tmp;
```

```
constexpr iterator& operator--()
requires ref_is_glvalue && bidirectional_range<Base> &&
         bidirectional_range<range_reference_t<Base>> &&
         common_range<range_reference_t<Base>>;
```

Effects: Equivalent to:

```
if (*outer_ == ranges::end(*parent_->base_))
    inner_ = ranges::end(as_lvalue(*--*outer_));
while (*inner_ == ranges::begin(as_lvalue(*outer_)))
    *inner_ = ranges::end(as_lvalue(*--*outer_));
--*inner_;
return *this;
```

```
constexpr iterator operator--(int)
requires ref_is_glvalue && bidirectional_range<Base> &&
         bidirectional_range<range_reference_t<Base>> &&
         common_range<range_reference_t<Base>>;
```

Effects: Equivalent to:

```
auto tmp = *this;
--*this;
return tmp;
```

```
friend constexpr bool operator==(const iterator& x, const iterator& y)
requires ref_is_glvalue && forward_range<Base> &&
         equality_comparable<iterator_t<range_reference_t<Base>>>;
```

Effects: Equivalent to: `return x.outer_ == y.outer_ && x.inner_ == y.inner_;`

```
friend constexpr void iter_swap(const iterator& x, const iterator& y)
    noexcept(noexcept(ranges::iter_swap(*x.inner_, *y.inner_)))
    requires indirectly_swappable<InnerIter>;
```

Effects: Equivalent to: `return ranges::iter_swap(*x.inner_, *y.inner_);`

26.7.14.4 Class template `join_view::sentinel` [range.join.sentinel]

```
namespace std::ranges {
    template<input_range V>
        requires view<V> && input_range<range_reference_t<V>>
        template<bool Const>
        struct join_view<V>::sentinel {
        private:
            using Parent = maybe_const<Const, join_view>;           // exposition only
            using Base = maybe_const<Const, V>;                     // exposition only
            sentinel_t<Base> end_ = sentinel_t<Base>();              // exposition only

        public:
            sentinel() = default;

            constexpr explicit sentinel(Parent& parent);
            constexpr sentinel(sentinel<!Const> s)
                requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;

            template<bool OtherConst>
                requires sentinel_for<sentinel_t<Base>, iterator_t<maybe_const<OtherConst, V>>>
            friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);
        };
    }
```

```
constexpr explicit sentinel(Parent& parent);
```

Effects: Initializes `end_` with `ranges::end(parent.base_)`.

```
constexpr sentinel(sentinel<!Const> s)
    requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
```

Effects: Initializes `end_` with `std::move(s.end_)`.

```
template<bool OtherConst>
    requires sentinel_for<sentinel_t<Base>, iterator_t<maybe_const<OtherConst, V>>>
friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);
```

Effects: Equivalent to: `return x.outer() == y.end_;`

26.7.15 Join with view [range.join.with]

26.7.15.1 Overview [range.join.with.overview]

`join_with_view` takes a view and a delimiter, and flattens the view, inserting every element of the delimiter in between elements of the view. The delimiter can be a single element or a view of elements.

The name `views::join_with` denotes a range adaptor object (26.7.2). Given subexpressions `E` and `F`, the expression `views::join_with(E, F)` is expression-equivalent to `join_with_view(E, F)`.

EXAMPLE

```
vector<string> vs = {"the", "quick", "brown", "fox"};
for (char c : vs | views::join_with('-')) {
    cout << c;
}
// The above prints the-quick-brown-fox
```

26.7.15.2 Class template `join_with_view` [range.join.with.view]

```
namespace std::ranges {
    template<class R, class P>
        concept compatible_joinable_ranges =           // exposition only
            common_with<range_value_t<R>, range_value_t<P>>> &&
            common_reference_with<range_reference_t<R>, range_reference_t<P>>> &&
```

```

common_reference_with<range_rvalue_reference_t<R>, range_rvalue_reference_t<P>>;

template<class R>
concept bidirectional-common = bidirectional_range<R> && common_range<R>;    // exposition only

        visit(ranges::iter_swap, x.inner_it_, y.inner_it_);
    }
};
}

```

iterator::iterator_concept is defined as follows:

- If *ref-is-glvalue* is true, *Base* models *bidirectional_range*, and *InnerBase* and *PatternBase* each model *bidirectional-common*, then *iterator_concept* denotes *bidirectional_iterator_tag*.
- Otherwise, if *ref-is-glvalue* is true and *Base* and *InnerBase* each model *forward_range*, then *iterator_concept* denotes *forward_iterator_tag*.
- Otherwise, *iterator_concept* denotes *input_iterator_tag*.

The member *typedef-name* *iterator_category* is defined if and only if *ref-is-glvalue* is true, and *Base* and *InnerBase* each model *forward_range*. In that case, *iterator::iterator_category* is defined as follows:

- Let *OUTERC* denote *iterator_traits<OuterIter>::iterator_category*, let *INNERC* denote *iterator_traits<InnerIter>::iterator_category*, and let *PATTERNC* denote *iterator_traits<PatternIter>::iterator_category*.

— If

```
is_reference_v<common_reference_t<iter_reference_t<InnerIter>,
                                iter_reference_t<PatternIter>>>
```

is false, `iterator_category` denotes `input_iterator_tag`.

- Otherwise, if *OUTERC*, *INNERC*, and *PATTERNC* each model `derived_from<bidirectional_iterator_category>` and *InnerBase* and *PatternBase* each model `common_range`, `iterator_category` denotes `bidirectional_iterator_tag`.
- Otherwise, if *OUTERC*, *INNERC*, and *PATTERNC* each model `derived_from<forward_iterator_tag>`, `iterator_category` denotes `forward_iterator_tag`.
- Otherwise, `iterator_category` denotes `input_iterator_tag`.

`iterator::value_type` denotes the type:

```
common_type_t<iter_value_t<InnerIter>, iter_value_t<PatternIter>>
```

`iterator::difference_type` denotes the type:

```
common_type_t<
    iter_difference_t<OuterIter>,
    iter_difference_t<InnerIter>,
    iter_difference_t<PatternIter>>
```

```
constexpr OuterIter& outer();
```

```
constexpr const OuterIter& outer() const;
```

Returns: `outer_it_` if *Base* models `forward_range`; otherwise, `*parent_ -> outer_it_`.

```
constexpr auto& update-inner();
```

Effects: Equivalent to:

```
if constexpr (ref-is-glvalue)
    return as-lvalue(*outer());
else
    return parent_ -> inner_.emplace-deref(outer());
```

```
constexpr auto& get-inner();
```

Effects: Equivalent to:

```
if constexpr (ref-is-glvalue)
    return as-lvalue(*outer());
else
    return *parent_ -> inner_;
```

```
constexpr void satisfy();
```

Effects: Equivalent to:

```
while (true) {
    if (inner_it_.index() == 0) {
        if (std::get<0>(inner_it_) != ranges::end(parent_ -> pattern_))
            break;
        inner_it_.emplace<1>(ranges::begin(update-inner()));
    } else {
        if (std::get<1>(inner_it_) != ranges::end(get-inner()))
            break;
        if (++outer() == ranges::end(parent_ -> base_)) {
            if constexpr (ref-is-glvalue)
                inner_it_.emplace<0>();
            break;
        }
        inner_it_.emplace<0>(ranges::begin(parent_ -> pattern_));
    }
}
```

NOTE 1 `join_with_view` iterators use the *satisfy* function to skip over empty inner ranges.

```
constexpr iterator(Parent& parent, OuterIter outer)
requires forward_range<Base>;
constexpr explicit iterator(Parent& parent)
requires (!forward_range<Base>);
```

Effects: Initializes *parent_* with `addressof(parent)`. For the first overload, also initializes *outer_it_* with `std::move(outer)`. Then, equivalent to:

```
if (outer() != ranges::end(parent->base_)) {
    inner_it_.emplace<1>(ranges::begin(update-inner()));
    satisfy();
}
```

```
constexpr iterator(iterator<!Const> i)
requires Const && convertible_to<iterator_t<V>, OuterIter> &&
    convertible_to<iterator_t<InnerRng>, InnerIter> &&
    convertible_to<iterator_t<Pattern>, PatternIter>;
```

Effects: Initializes *outer_it_* with `std::move(i.outer_it_)` and *parent_* with `i.parent_`. Then, equivalent to:

```
if (i.inner_it_.index() == 0)
    inner_it_.emplace<0>(std::get<0>(std::move(i.inner_it_)));
else
    inner_it_.emplace<1>(std::get<1>(std::move(i.inner_it_)));
```

NOTE 2 *Const* can only be true when *Base* models *forward_range*.

```
constexpr decltype(auto) operator*() const;
```

Effects: Equivalent to:

```
using reference =
    common_reference_t<iter_reference_t<InnerIter>, iter_reference_t<PatternIter>>;
return visit([](auto& it) -> reference { return *it; }, inner_it_);
```

```
constexpr iterator& operator++();
```

Effects: Equivalent to:

```
visit([](auto& it){ ++it; }, inner_it_);
satisfy();
return *this;
```

```
constexpr void operator++(int);
```

Effects: Equivalent to `++*this`.

```
constexpr iterator operator++(int)
requires ref-is-glvalue && forward_iterator<OuterIter> && forward_iterator<InnerIter>;
```

Effects: Equivalent to:

```
iterator tmp = *this;
++*this;
return tmp;
```

```
constexpr iterator& operator--()
requires ref-is-glvalue && bidirectional_range<Base> &&
    bidirectional_common<InnerBase> && bidirectional_common<PatternBase>;
```

Effects: Equivalent to:

```
if (outer_it_ == ranges::end(parent->base_)) {
    auto&& inner = *--outer_it_;
    inner_it_.emplace<1>(ranges::end(inner));
}
```

```
while (true) {
    if (inner_it_.index() == 0) {
        auto& it = std::get<0>(inner_it_);
        if (it == ranges::begin(parent->pattern_)) {
            auto&& inner = *--outer_it_;
```

```

        inner_it_.emplace<1>(ranges::end(inner));
    } else {
        break;
    }
} else {
    auto& it = std::get<1>(inner_it_);
    auto&& inner = *outer_it_;
    if (it == ranges::begin(inner)) {
        inner_it_.emplace<0>(ranges::end(parent->pattern));
    } else {
        break;
    }
}
}
}
visit([](auto& it){ --it; }, inner_it_);
return *this;

```

```

constexpr iterator operator--(int)
requires ref-is-glvalue && bidirectional_range<Base> &&
        bidirectional-common<InnerBase> && bidirectional-common<PatternBase>;

```

Effects: Equivalent to:

```

    iterator tmp = *this;
    --*this;
    return tmp;

```

```

friend constexpr bool operator==(const iterator& x, const iterator& y)
requires ref-is-glvalue && forward_range<Base> &&
        equality_comparable<InnerIter>;

```

Effects: Equivalent to:

```

    return x.outer_it_ == y.outer_it_ && x.inner_it_ == y.inner_it_;

```

26.7.15.4 Class template `join_with_view::sentinel` [range.join.with.sentinel]

```

namespace std::ranges {
    template<input_range V, forward_range Pattern>
    requires view<V> && input_range<range_reference_t<V>>
            && view<Pattern> && compatible-joinable-ranges<range_reference_t<V>, Pattern>
    template<bool Const>
    class join_with_view<V, Pattern>::sentinel {
        using Parent = maybe-const<Const, join_with_view>; // exposition only
        using Base = maybe-const<Const, V>; // exposition only
        sentinel_t<Base> end_ = sentinel_t<Base>(); // exposition only

        constexpr explicit sentinel(Parent& parent); // exposition only

    public:
        sentinel() = default;
        constexpr sentinel(sentinel<!Const> s)
            requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;

        friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);
    };
}

```

```

constexpr explicit sentinel(Parent& parent);

```

Effects: Initializes `end_` with `ranges::end(parent.base_)`.

```

constexpr sentinel(sentinel<!Const> s)
requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;

```

Effects: Initializes `end_` with `std::move(s.end_)`.

```
template<bool OtherConst>
    requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
friend constexpr bool operator==(const iterator_t<OtherConst>& x, const sentinel_t& y);

Effects: Equivalent to: return x.outer() == y.end_;
```

26.7.16 Lazy split view [range.lazy.split]

26.7.16.1 Overview [range.lazy.split.overview]

`lazy_split_view` takes a view and a delimiter, and splits the view into subranges on the delimiter. The delimiter can be a single element or a view of elements.

The name `views::lazy_split` denotes a range adaptor object (26.7.2). Given subexpressions `E` and `F`, the expression `views::lazy_split(E, F)` is expression-equivalent to `lazy_split_view(E, F)`.

EXAMPLE

```
string str{"the quick brown fox"};
for (auto word : str | views::lazy_split(' ')) {
    for (char ch : word)
        cout << ch;
    cout << ' ';
}
// The above prints the*quick*brown*fox*
```

26.7.16.2 Class template `lazy_split_view` [range.lazy.split.view]

```
namespace std::ranges {
    template<auto> struct require-constant; // exposition only

    template<class R>
    concept tiny-range = // exposition only
        sized_range<R> &&
        requires { typename require-constant<remove_reference_t<R>::size()>; } &&
        (remove_reference_t<R>::size() <= 1);

    template<input_range V, forward_range Pattern>
    requires view<V> && view<Pattern> &&
        indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to> &&
        (forward_range<V> || tiny-range<Pattern>)
    class lazy_split_view : public view_interface<lazy_split_view<V, Pattern>> {
    private:
        V base_ = V(); // exposition only
        Pattern pattern_ = Pattern(); // exposition only

        non-propagating-cache<iterator_t<V>> current_; // exposition only, present only
        // if forward_range<V> is false

        // 26.7.16.3, class template lazy_split_view::outer-iterator
        template<bool> struct outer-iterator; // exposition only

        // 26.7.16.5, class template lazy_split_view::inner-iterator
        template<bool> struct inner-iterator; // exposition only

    public:

                Parent* parent_ = nullptr; // exposition only

                iterator_t<Base> current_ = iterator_t<Base>(); // exposition only, present only
                                                                    // if V models forward_range

                bool trailing_empty_ = false; // exposition only
            };
}

```

```

public:
    using iterator_concept =
        conditional_t<forward_range<Base>, forward_iterator_tag, input_iterator_tag>;

    using iterator_category = input_iterator_tag;           // present only if Base
                                                         // models forward_range

    // 26.7.16.4, class lazy_split_view::outer-iterator::value_type
    struct value_type;
    using difference_type = range_difference_t<Base>;

    outer-iterator() = default;
    constexpr explicit outer-iterator(Parent& parent)
        requires (!forward_range<Base>);
    constexpr outer-iterator(Parent& parent, iterator_t<Base> current)
        requires forward_range<Base>;
    constexpr outer-iterator(outer-iterator<!Const> i)
        requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;

    constexpr value_type operator*() const;

    constexpr outer-iterator& operator++();
    constexpr decltype(auto) operator++(int) {
        if constexpr (forward_range<Base>) {
            auto tmp = *this;
            ++*this;
            return tmp;
        } else
            ++*this;
    }

        requires forward_range<Base>;

    friend constexpr bool operator==(const outer-iterator& x, default_sentinel_t);
};

```

Many of the specifications in 26.7.16 refer to the notional member *current* of *outer-iterator*. *current* is equivalent to *current_* if *V* models *forward_range*, and **parent_*→*current_* otherwise.

```

constexpr explicit outer-iterator(Parent& parent)
    requires (!forward_range<Base>);

    Effects: Initializes parent_ with addressof(parent).

constexpr outer-iterator(Parent& parent, iterator_t<Base> current)
    requires forward_range<Base>;

    Effects: Initializes parent_ with addressof(parent) and current_ with std::move(current).

constexpr outer-iterator(outer-iterator<!Const> i)
    requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;

    Effects: Initializes parent_ with i.parent_ and current_ with std::move(i.current_).

constexpr value_type operator*() const;

    Effects: Equivalent to: return value_type{*this};

constexpr outer-iterator& operator++();

    Effects: Equivalent to:

        const auto end = ranges::end(parent_→base_);
        if (current == end) {
            trailing_empty_ = false;

```

```

        return *this;
    }
    const auto [pbegin, pend] = subrange{parent_ -> pattern_};
    if (pbegin == pend) ++current;
    else if constexpr (tiny-range<Pattern>) {
        current = ranges::find(std::move(current), end, *pbegin);
        if (current != end) {
            ++current;
            if (current == end)
                trailing_empty_ = true;
        }
    }
    else {
        do {
            auto [b, p] = ranges::mismatch(current, end, pbegin, pend);
            if (p == pend) {
                current = b;
                if (current == end)
                    trailing_empty_ = true;
                break; // The pattern matched; skip it
            }
        } while (++current != end);
    }
    return *this;
}

friend constexpr bool operator==(const outer-iterator& x, const outer-iterator& y)
    requires forward_range<Base>;

Effects: Equivalent to:

    return x.current_ == y.current_ && x.trailing_empty_ == y.trailing_empty_;

friend constexpr bool operator==(const outer-iterator& x, default_sentinel_t);

Effects: Equivalent to:

    return x.current == ranges::end(x.parent_ -> base_) && !x.trailing_empty_;

```

26.7.16.4 Class lazy_split_view::outer-iterator::value_type [range.lazy.split.outer.value]

```

namespace std::ranges {
    template<input_range V, forward_range Pattern>
        requires view<V> && view<Pattern> &&
            indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to> &&
                (forward_range<V> || tiny-range<Pattern>)
    template<bool Const>
    struct lazy_split_view<V, Pattern>::outer-iterator<Const>::value_type
        : view_interface<value_type> {

        if (cur == end) return true;
        if (pcur == pend) return x.incremented_;
        do {
            if (*cur != *pcur) return false;
            if (++pcur == pend) return true;
        } while (++cur != end);
        return false;
    }
```

```
friend constexpr void iter_swap(const inner-iterator& x, const inner-iterator& y)
    noexcept(noexcept(ranges::iter_swap(x.i_.current, y.i_.current)))
    requires indirectly_swappable<iterator_t<Base>>;
```

Effects: Equivalent to `ranges::iter_swap(x.i_.current, y.i_.current)`.

26.7.17 Split view

[range.split]

26.7.17.1 Overview

[range.split.overview]

`split_view` takes a view and a delimiter, and splits the view into subranges on the delimiter. The delimiter can be a single element or a view of elements.

The name `views::split` denotes a range adaptor object (26.7.2). Given subexpressions `E` and `F`, the expression `views::split(E, F)` is expression-equivalent to `split_view(E, F)`.

EXAMPLE

```
string str{"the quick brown fox"};
```

```

for (auto word : views::split(str, ' ')) {
    cout << string_view(word) << '*';
}
// The above prints the*quick*brown*fox*

```

26.7.17.2 Class template `split_view`

[range.split.view]

```

namespace std::ranges {
    template<forward_range V, forward_range Pattern>
        requires view<V> && view<Pattern> &&
            indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to>
        class split_view : public view_interface<split_view<V, Pattern>> {
        private:
            V base_ = V(); // exposition only
            Pattern pattern_ = Pattern(); // exposition only

            // 26.7.17.3, class split_view::iterator
            struct iterator; // exposition only

            // 26.7.17.4, class split_view::sentinel
            struct sentinel; // exposition only

        public:
            split_view()
                requires default_initializable<V> && default_initializable<Pattern> = default;
            constexpr explicit split_view(V base, Pattern pattern);

            template<forward_range R>
                requires constructible_from<V, views::all_t<R>> &&
                    constructible_from<Pattern, single_view<range_value_t<R>>>
            constexpr explicit split_view(R&& r, range_value_t<R> e);

            constexpr V base() const & requires copy_constructible<V> { return base_; }
            constexpr V base() && { return std::move(base_); }

            constexpr iterator begin();

            constexpr auto end() {
                if constexpr (common_range<V>) {
                    return iterator{*this, ranges::end(base_), {}};
                } else {
                    return sentinel{*this};
                }
            }

            constexpr subrange<iterator_t<V>> find_next(iterator_t<V>); // exposition only
        };

        template<class R, class P>
            split_view(R&&, P&&) -> split_view<views::all_t<R>, views::all_t<P>>;

        template<forward_range R>
            split_view(R&&, range_value_t<R>)
                -> split_view<views::all_t<R>, single_view<range_value_t<R>>>;
    }

```

constexpr explicit split_view(V base, Pattern pattern);

Effects: Initializes *base_* with `std::move(base)`, and *pattern_* with `std::move(pattern)`.

```

template<forward_range R>
    requires constructible_from<V, views::all_t<R>> &&
        constructible_from<Pattern, single_view<range_value_t<R>>>

```

```
constexpr explicit split_view(R&& r, range_value_t<R> e);
```

Effects: Initializes *base_* with `views::all(std::forward<R>(r))`, and *pattern_* with `views::single(std::move(e))`.

```
constexpr iterator begin();
```

Returns: `{*this, ranges::begin(base_), find-next(ranges::begin(base_))}`.

Remarks: In order to provide the amortized constant time complexity required by the `range` concept, this function caches the result within the `split_view` for use on subsequent calls.

```
constexpr subrange<iterator_t<V>> find-next(iterator_t<V> it);
```

Effects: Equivalent to:

```
auto [b, e] = ranges::search(subrange(it, ranges::end(base_)), pattern_);
if (b != ranges::end(base_) && ranges::empty(pattern_)) {
    ++b;
    ++e;
}
return {b, e};
```

26.7.17.3 Class `split_view::iterator`

[`range.split.iterator`]

```
namespace std::ranges {
    template<forward_range V, forward_range Pattern>
        requires view<V> && view<Pattern> &&
            indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to>
        class split_view<V, Pattern>::iterator {
        private:
            split_view* parent_ = nullptr;           // exposition only
            iterator_t<V> cur_ = iterator_t<V>();    // exposition only
            subrange<iterator_t<V>> next_ = subrange<iterator_t<V>>(); // exposition only
            bool trailing_empty_ = false;             // exposition only

        public:
            using iterator_concept = forward_iterator_tag;
            using iterator_category = input_iterator_tag;
            using value_type = subrange<iterator_t<V>>;
            using difference_type = range_difference_t<V>;

            iterator() = default;
            constexpr iterator(split_view& parent, iterator_t<V> current, subrange<iterator_t<V>> next);

            constexpr iterator_t<V> base() const;
            constexpr value_type operator*() const;

            constexpr iterator& operator++();
            constexpr iterator operator++(int);

            friend constexpr bool operator==(const iterator& x, const iterator& y);
        };
    }
```

```
constexpr iterator(split_view& parent, iterator_t<V> current, subrange<iterator_t<V>> next);
```

Effects: Initializes *parent_* with `addressof(parent)`, *cur_* with `std::move(current)`, and *next_* with `std::move(next)`.

```
constexpr iterator_t<V> base() const;
```

Effects: Equivalent to `return cur_;`

```
constexpr value_type operator*() const;
```

Effects: Equivalent to `return {cur_, next_.begin()};`

```
constexpr iterator& operator++();
```

Effects: Equivalent to:

```
cur_ = next_.begin();
if (cur_ != ranges::end(parent_>base_)) {
    cur_ = next_.end();
    if (cur_ == ranges::end(parent_>base_)) {
        trailing_empty_ = true;
        next_ = {cur_, cur_};
    } else {
        next_ = parent_>find-next(cur_);
    }
} else {
    trailing_empty_ = false;
}
return *this;
```

```
constexpr iterator operator++(int);
```

Effects: Equivalent to:

```
auto tmp = *this;
++*this;
return tmp;
```

```
friend constexpr bool operator==(const iterator& x, const iterator& y);
```

Effects: Equivalent to:

```
return x.cur_ == y.cur_ && x.trailing_empty_ == y.trailing_empty_;
```

26.7.17.4 Class `split_view::sentinel`

[range.split.sentinel]

```
namespace std::ranges {
    template<forward_range V, forward_range Pattern>
    requires view<V> && view<Pattern> &&
        indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to>
    struct split_view<V, Pattern>::sentinel {
    private:
        sentinel_t<V> end_ = sentinel_t<V>(); // exposition only

    public:
        sentinel() = default;
        constexpr explicit sentinel(split_view& parent);

        friend constexpr bool operator==(const iterator& x, const sentinel& y);
    };
}
```

```
constexpr explicit sentinel(split_view& parent);
```

Effects: Initializes `end_` with `ranges::end(parent.base_)`.

```
friend constexpr bool operator==(const iterator& x, const sentinel& y);
```

Effects: Equivalent to: `return x.cur_ == y.end_ && !x.trailing_empty_;`

26.7.18 Counted view

[range.counted]

A counted view presents a view of the elements of the counted range (25.3.1) `i + [0, n)` for an iterator `i` and non-negative integer `n`.

The name `views::counted` denotes a customization point object (16.3.3.3.5). Let `E` and `F` be expressions, let `T` be `decay_t<decltype((E))>`, and let `D` be `iter_difference_t<T>`. If `decltype((F))` does not model `convertible_to<D>`, `views::counted(E, F)` is ill-formed.

NOTE This case can result in substitution failure when `views::counted(E, F)` appears in the immediate context of a template instantiation.

Otherwise, `views::counted(E, F)` is expression-equivalent to:

- If `T` models `contiguous_iterator`, then `span(to_address(E), static_cast<size_t>(static_cast<D>(F)))`.
- Otherwise, if `T` models `random_access_iterator`, then `subrange(E, E + static_cast<D>(F))`, except that `E` is evaluated only once.
- Otherwise, `subrange(counted_iterator(E, F), default_sentinel)`.

26.7.19 Common view

[range.common]

26.7.19.1 Overview

[range.common.overview]

`common_view` takes a view which has different types for its iterator and sentinel and turns it into a view of the same elements with an iterator and sentinel of the same type.

NOTE `common_view` is useful for calling legacy algorithms that expect a range's iterator and sentinel types to be the same.

The name `views::common` denotes a range adaptor object (26.7.2). Given a subexpression `E`, the expression `views::common(E)` is expression-equivalent to:

- `views::all(E)`, if `decltype((E))` models `common_range` and `views::all(E)` is a well-formed expression.
- Otherwise, `common_view{E}`.

EXAMPLE

// Legacy algorithm:

```
template<class ForwardIterator>
size_t count(ForwardIterator first, ForwardIterator last);
```

```
template<forward_range R>
void my_algo(R&& r) {
    auto&& common = views::common(r);
    auto cnt = count(common.begin(), common.end());
    // ...
}
```

26.7.19.2 Class template `common_view`

[range.common.view]

```
namespace std::ranges {
    template<view V>
        requires (!common_range<V> && copyable<iterator_t<V>>())
        class common_view : public view_interface<common_view<V>> {
        private:
            V base_ = V(); // exposition only

        public:
            common_view() requires default_initializable<V> = default;

            constexpr explicit common_view(V r);

            constexpr V base() const & requires copy_constructible<V> { return base_; }
            constexpr V base() && { return std::move(base_); }

            constexpr auto begin() {
                if constexpr (random_access_range<V> && sized_range<V>)
                    return ranges::begin(base_);
                else
                    return common_iterator<iterator_t<V>, sentinel_t<V>>(ranges::begin(base_));
            }

            constexpr auto begin() const requires range<const V> {
                if constexpr (random_access_range<const V> && sized_range<const V>)
                    return ranges::begin(base_);
                else
                    return common_iterator<iterator_t<const V>, sentinel_t<const V>>(ranges::begin(base_));
            }
        };
}
```

```

}

constexpr auto end() {
    if constexpr (random_access_range<V> && sized_range<V>)
        return ranges::begin(base_) + ranges::distance(base_);
    else
        return common_iterator<iterator_t<V>, sentinel_t<V>>(ranges::end(base_));
}

constexpr auto end() const requires range<const V> {
    if constexpr (random_access_range<const V> && sized_range<const V>)
        return ranges::begin(base_) + ranges::distance(base_);
    else
        return common_iterator<iterator_t<const V>, sentinel_t<const V>>(ranges::end(base_));
}

constexpr auto size() requires sized_range<V> {
    return ranges::size(base_);
}
constexpr auto size() const requires sized_range<const V> {
    return ranges::size(base_);
}
};

template<class R>
    common_view(R&&) -> common_view<views::all_t<R>>;
}

constexpr explicit common_view(V base);
    Effects: Initializes base_ with std::move(base).

```

26.7.20 Reverse view

[range.reverse]

26.7.20.1 Overview

[range.reverse.overview]

`reverse_view` takes a bidirectional view and produces another view that iterates the same elements in reverse order.

The name `views::reverse` denotes a range adaptor object (26.7.2). Given a subexpression *E*, the expression `views::reverse(E)` is expression-equivalent to:

- If the type of *E* is a (possibly cv-qualified) specialization of `reverse_view`, equivalent to `E.base()`.
- Otherwise, if the type of *E* is *cv* `subrange<reverse_iterator<I>, reverse_iterator<I>, K>` for some iterator type *I* and value *K* of type `subrange_kind`,

- if *K* is `subrange_kind::sized`, equivalent to:

```
subrange<I, I, K>(E.end().base(), E.begin().base(), E.size())
```

- otherwise, equivalent to:

```
subrange<I, I, K>(E.end().base(), E.begin().base())
```

However, in either case *E* is evaluated only once.

- Otherwise, equivalent to `reverse_view{E}`.

EXAMPLE

```

vector<int> is {0,1,2,3,4};
for (int i : is | views::reverse)
    cout << i << ' '; // prints 4 3 2 1 0

```

26.7.20.2 Class template `reverse_view`

[range.reverse.view]

```

namespace std::ranges {
    template<view V>
        requires bidirectional_range<V>
        class reverse_view : public view_interface<reverse_view<V>> {
        private:
            V base_ = V(); // exposition only

```

```

public:
    reverse_view() requires default_initializable<V> = default;

    constexpr explicit reverse_view(V r);

    constexpr V base() const & requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }

    constexpr reverse_iterator<iterator_t<V>> begin();
    constexpr reverse_iterator<iterator_t<V>> begin() requires common_range<V>;
    constexpr auto begin() const requires common_range<const V>;

    constexpr reverse_iterator<iterator_t<V>> end();
    constexpr auto end() const requires common_range<const V>;

    constexpr auto size() requires sized_range<V> {
        return ranges::size(base_);
    }

    constexpr auto size() const requires sized_range<const V> {
        return ranges::size(base_);
    }
};

template<class R>
    reverse_view(R&&) -> reverse_view<views::all_t<R>>;
}

constexpr explicit reverse_view(V base);
    Effects: Initializes base_ with std::move(base).

constexpr reverse_iterator<iterator_t<V>> begin();
    Returns:
        make_reverse_iterator(ranges::next(ranges::begin(base_), ranges::end(base_)))

    Remarks: In order to provide the amortized constant time complexity required by the range concept,
    this function caches the result within the reverse_view for use on subsequent calls.

constexpr reverse_iterator<iterator_t<V>> begin() requires common_range<V>;
constexpr auto begin() const requires common_range<const V>;
    Effects: Equivalent to: return make_reverse_iterator(ranges::end(base_));

constexpr reverse_iterator<iterator_t<V>> end();
constexpr auto end() const requires common_range<const V>;
    Effects: Equivalent to: return make_reverse_iterator(ranges::begin(base_));

```

26.7.21 As const view [range.as.const]

26.7.21.1 Overview [range.as.const.overview]

`as_const_view` presents a view of an underlying sequence as constant. That is, the elements of an `as_const_view` cannot be modified.

The name `views::as_const` denotes a range adaptor object (26.7.2). Let *E* be an expression, let *T* be `decltype((E))`, and let *U* be `remove_cvref_t<T>`. The expression `views::as_const(E)` is expression-equivalent to:

- If `views::all_t<T>` models `constant_range`, then `views::all(E)`.
- Otherwise, if *U* denotes `empty_view<X>` for some type *X*, then `auto(views::empty<const X>)`.
- Otherwise, if *U* denotes `span<X, Extent>` for some type *X* and some extent *Extent*, then `span<const X, Extent>(E)`.
- Otherwise, if *U* denotes `ref_view<X>` for some type *X* and `const X` models `constant_range`, then `ref_view(static_cast<const X&>(E.base()))`.

- Otherwise, if E is an lvalue, `const U` models `constant_range`, and U does not model `view`, then `ref_view(static_cast<const U&>(E))`.
- Otherwise, `as_const_view(E)`.

EXAMPLE

```
template<constant_range R>
void cant_touch_this(R&&);

vector<char> hammer = {'m', 'c'};
span<char> beat = hammer;
cant_touch_this(views::as_const(beat));           // will not modify the elements of hammer
```

26.7.21.2 Class template `as_const_view`

[range.as.const.view]

```
namespace std::ranges {
    template<view V>
        requires input_range<V>
    class as_const_view : public view_interface<as_const_view<V>> {
        V base_ = V();           // exposition only

    public:
        as_const_view() requires default_initializable<V> = default;
        constexpr explicit as_const_view(V base_);

        constexpr V base() const & requires copy_constructible<V> { return base_; }
        constexpr V base() && { return std::move(base_); }

        constexpr auto begin() requires (!simple_view<V>) { return ranges::cbegin(base_); }
        constexpr auto begin() const requires range<const V> { return ranges::cbegin(base_); }

        constexpr auto end() requires (!simple_view<V>) { return ranges::cend(base_); }
        constexpr auto end() const requires range<const V> { return ranges::cend(base_); }

        constexpr auto size() requires sized_range<V> { return ranges::size(base_); }
        constexpr auto size() const requires sized_range<const V> { return ranges::size(base_); }
    };

    template<class R>
        as_const_view(R&&) -> as_const_view<views::all_t<R>>;
}

constexpr explicit as_const_view(V base_);

Effects: Initializes base_ with std::move(base).
```

26.7.22 Elements view

[range.elements]

26.7.22.1 Overview

[range.elements.overview]

`elements_view` takes a view of tuple-like values and a `size_t`, and produces a view with a value-type of the N^{th} element of the adapted view's value-type.

The name `views::elements<N>` denotes a range adaptor object (26.7.2). Given a subexpression E and constant expression N, the expression `views::elements<N>(E)` is expression-equivalent to `elements_view<views::all_t<decltype((E))>, N>{E}`.

EXAMPLE 1

```
auto historical_figures = map{
    pair{"Lovelace"sv, 1815},
    {"Turing"sv, 1912},
    {"Babbage"sv, 1791},
    {"Hamilton"sv, 1936}
};

auto names = historical_figures | views::elements<0>;
```

```

for (auto&& name : names) {
    cout << name << ' ';           // prints Babbage Hamilton Lovelace Turing
}

auto birth_years = historical_figures | views::elements<1>;
for (auto&& born : birth_years) {
    cout << born << ' ';           // prints 1791 1936 1815 1912
}

```

`keys_view` is an alias for `elements_view<R, 0>`, and is useful for extracting keys from associative containers.

EXAMPLE 2

```

auto names = historical_figures | views::keys;
for (auto&& name : names) {
    cout << name << ' ';           // prints Babbage Hamilton Lovelace Turing
}

```

`values_view` is an alias for `elements_view<R, 1>`, and is useful for extracting values from associative containers.

EXAMPLE 3

```

auto is_even = [](const auto x) { return x % 2 == 0; };
cout << ranges::count_if(historical_figures | views::values, is_even); // prints 2

```

26.7.22.2 Class template `elements_view`

[`range.elements.view`]

```

namespace std::ranges {
    template<class T, size_t N>
    concept has_tuple_element = // exposition only
        tuple_like<T> && N < tuple_size_v<T>;

    template<class T, size_t N>
    concept returnable_element = // exposition only
        is_reference_v<T> || move_constructible<tuple_element_t<N, T>>;

    template<input_range V, size_t N>
    requires view<V> && has_tuple_element<range_value_t<V>, N> &&
        has_tuple_element<remove_reference_t<range_reference_t<V>>, N> &&
        returnable_element<range_reference_t<V>, N>
    class elements_view : public view_interface<elements_view<V, N>> {
    public:
        elements_view() requires default_initializable<V> = default;
        constexpr explicit elements_view(V base);

        constexpr V base() const & requires copy_constructible<V> { return base_; }
        constexpr V base() && { return std::move(base_); }

        constexpr auto begin() requires (!simple_view<V>)
        { return iterator<false>(ranges::begin(base_)); }

        constexpr auto begin() const requires range<const V>
        { return iterator<true>(ranges::begin(base_)); }

        constexpr auto end() requires (!simple_view<V> && !common_range<V>)
        { return sentinel<false>(ranges::end(base_)); }

        constexpr auto end() requires (!simple_view<V> && common_range<V>)
        { return iterator<false>(ranges::end(base_)); }

        constexpr auto end() const requires range<const V>
        { return sentinel<true>(ranges::end(base_)); }

        constexpr auto end() const requires common_range<const V>
        { return iterator<true>(ranges::end(base_)); }
    };
}

```

```

constexpr auto size() requires sized_range<V>
{ return ranges::size(base_); }

constexpr auto size() const requires sized_range<const V>
{ return ranges::size(base_); }

private:
    // 26.7.22.3, class template elements_view::iterator
    template<bool> class iterator; // exposition only

    // 26.7.22.4, class template elements_view::sentinel
    template<bool> class sentinel; // exposition only

    V base_ = V(); // exposition only
};

constexpr explicit elements_view(V base);
    Effects: Initializes base_ with std::move(base).

```

26.7.22.3 Class template `elements_view::iterator` [range.elements.iterator]

```

namespace std::ranges {
    template<input_range V, size_t N>
        requires view<V> && has_tuple_element<range_value_t<V>, N> &&
            has_tuple_element<remove_reference_t<range_reference_t<V>>, N> &&
            returnable_element<range_reference_t<V>, N>
        template<bool Const>
        class elements_view<V, N>::iterator {
            using Base = maybe_const<Const, V>; // exposition only

            iterator_t<Base> current_ = iterator_t<Base>(); // exposition only

            static constexpr decltype(auto) get_element(const iterator_t<Base>& i); // exposition only

        public:
            using iterator_concept = see below;
            using iterator_category = see below; // not always present
            using value_type = remove_cvref_t<tuple_element_t<N, range_value_t<Base>>>;
            using difference_type = range_difference_t<Base>;

            iterator() requires default_initializable<iterator_t<Base>> = default;
            constexpr explicit iterator(iterator_t<Base> current);
            constexpr iterator(iterator<!Const> i)
                requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;

            constexpr const iterator_t<Base>& base() const & noexcept;
            constexpr iterator_t<Base> base() &&;

            constexpr decltype(auto) operator*() const
            { return get_element(current_); }

            constexpr iterator& operator++();
            constexpr void operator++(int);
            constexpr iterator operator++(int) requires forward_range<Base>;

            constexpr iterator& operator--() requires bidirectional_range<Base>;
            constexpr iterator operator--(int) requires bidirectional_range<Base>;

            constexpr iterator& operator+=(difference_type x)
                requires random_access_range<Base>;
            constexpr iterator& operator-=(difference_type x)
                requires random_access_range<Base>;

```

```

constexpr decltype(auto) operator[](difference_type n) const
    requires random_access_range<Base>
{ return get-element(current_ + n); }

friend constexpr bool operator==(const iterator& x, const iterator& y)
    requires equality_comparable<iterator_t<Base>>;

friend constexpr bool operator<(const iterator& x, const iterator& y)
    requires random_access_range<Base>;
friend constexpr bool operator>(const iterator& x, const iterator& y)
    requires random_access_range<Base>;
friend constexpr bool operator<=(const iterator& x, const iterator& y)
    requires random_access_range<Base>;
friend constexpr bool operator>=(const iterator& x, const iterator& y)
    requires random_access_range<Base>;
friend constexpr auto operator<=(const iterator& x, const iterator& y)
    requires random_access_range<Base> && three_way_comparable<iterator_t<Base>>;

friend constexpr iterator operator+(const iterator& x, difference_type y)
    requires random_access_range<Base>;
friend constexpr iterator operator+(difference_type x, const iterator& y)
    requires random_access_range<Base>;
friend constexpr iterator operator-(const iterator& x, difference_type y)
    requires random_access_range<Base>;
friend constexpr difference_type operator-(const iterator& x, const iterator& y)
    requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;
};
}

```

The member *typedef-name* `iterator_concept` is defined as follows:

- If *Base* models `random_access_range`, then `iterator_concept` denotes `random_access_iterator_tag`.
- Otherwise, if *Base* models `bidirectional_range`, then `iterator_concept` denotes `bidirectional_iterator_tag`.
- Otherwise, if *Base* models `forward_range`, then `iterator_concept` denotes `forward_iterator_tag`.
- Otherwise, `iterator_concept` denotes `input_iterator_tag`.

The member *typedef-name* `iterator_category` is defined if and only if *Base* models `forward_range`. In that case, `iterator_category` is defined as follows: Let *C* denote the type `iterator_traits<iterator_t<Base>>::iterator_category`.

- If `std::get<N>(*current_)` is an rvalue, `iterator_category` denotes `input_iterator_tag`.
- Otherwise, if *C* models `derived_from<random_access_iterator_tag>`, `iterator_category` denotes `random_access_iterator_tag`.
- Otherwise, `iterator_category` denotes *C*.

```
static constexpr decltype(auto) get-element(const iterator_t<Base>& i);
```

Effects: Equivalent to:

```

if constexpr (is_reference_v<range_reference_t<Base>>) {
    return std::get<N>(*i);
} else {
    using E = remove_cv_t<tuple_element_t<N, range_reference_t<Base>>>;
    return static_cast<E>(std::get<N>(*i));
}

```

```
constexpr explicit iterator(iterator_t<Base> current);
```

Effects: Initializes *current_* with `std::move(current)`.

```
constexpr iterator(iterator<!Const> i)
    requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;
```

Effects: Initializes *current_* with `std::move(i.current_)`.

```

    operator-(const sentinel& x, const iterator<OtherConst>& y);
    Effects: Equivalent to: return x.end_ - y.current_;
```

26.7.23 Enumerate view

[range.enumerate]

26.7.23.1 Overview

[range.enumerate.overview]

`enumerate_view` is a view whose elements represent both the position and value from a sequence of elements. The name `views::enumerate` denotes a range adaptor object. Given a subexpression *E*, the expression `views::enumerate(E)` is expression-equivalent to `enumerate_view<views::all_t<decltype((E))>>(E)`.

EXAMPLE

```
vector<int> vec{ 1, 2, 3 };
for (auto [index, value] : views::enumerate(vec))
    cout << index << ":" << value << ' '; // prints 0:1 1:2 2:3
```

26.7.23.2 Class template `enumerate_view`

[range.enumerate.view]

```
namespace std::ranges {
    template<view V>
        requires range-with-movable-references<V>
    class enumerate_view : public view_interface<enumerate_view<V>> {
        V base_ = V(); // exposition only

        // 26.7.23.3, class template enumerate_view::iterator
        template<bool Const>
            class iterator; // exposition only

        // 26.7.23.4, class template enumerate_view::sentinel
        template<bool Const>
            class sentinel; // exposition only

    public:
        constexpr enumerate_view() requires default_initializable<V> = default;
        constexpr explicit enumerate_view(V base);

        constexpr auto begin() requires (!simple-view<V>)
        { return iterator<false>(ranges::begin(base_), 0); }
        constexpr auto begin() const requires range-with-movable-references<const V>
        { return iterator<true>(ranges::begin(base_), 0); }
```

```

constexpr auto end() requires (!simple-view<V>) {
    if constexpr (common_range<V> && sized_range<V>)
        return iterator<false>(ranges::end(base_), ranges::distance(base_));
    else
        return sentinel<false>(ranges::end(base_));
}
constexpr auto end() const requires range-with-movable-references<const V> {
    if constexpr (common_range<const V> && sized_range<const V>)
        return iterator<true>(ranges::end(base_), ranges::distance(base_));
    else
        return sentinel<true>(ranges::end(base_));
}

constexpr auto size() requires sized_range<V>
{ return ranges::size(base_); }
constexpr auto size() const requires sized_range<const V>
{ return ranges::size(base_); }

constexpr V base() const & requires copy_constructible<V> { return base_; }
constexpr V base() && { return std::move(base_); }
};

template<class R>
    enumerate_view(R&&) -> enumerate_view<views::all_t<R>>;
}

constexpr explicit enumerate_view(V base);

Effects: Initializes base_ with std::move(base).

```

26.7.23.3 Class template `enumerate_view::iterator` [range.enumerate.iterator]

```

namespace std::ranges {

operator-(const sentinel_t& x, const iterator_t<OtherConst>& y);
```

Effects: Equivalent to: `return x.end_ - y.current_;`

26.7.24 Zip view

[range.zip]

26.7.24.1 Overview

[range.zip.overview]

`zip_view` takes any number of views and produces a view of tuples of references to the corresponding elements of the constituent views.

The name `views::zip` denotes a customization point object (16.3.3.3.5). Given a pack of subexpressions `Es...`, the expression `views::zip(Es...)` is expression-equivalent to

- `auto(views::empty<tuple<>>)` if `Es` is an empty pack,
- otherwise, `zip_view<views::all_t<decltype((Es))>...>(Es...)`.

EXAMPLE

```
vector v = {1, 2};
list l = {'a', 'b', 'c'};

auto z = views::zip(v, l);
range_reference_t<decltype(z)> f = z.front(); // f is a tuple<int&, char&>
// that refers to the first element of v and l

for (auto&& [x, y] : z) {
    cout << '(' << x << ", " << y << " "; // prints (1, a) (2, b)
}
```

26.7.24.2 Class template `zip_view`

[range.zip.view]

```
namespace std::ranges {
    template<class... Rs>
    concept zip_is_common = // exposition only
        (sizeof...(Rs) == 1 && (common_range<Rs> && ...)) ||
        (!bidirectional_range<Rs> && ... && (common_range<Rs> && ...)) ||
        ((random_access_range<Rs> && ... && (sized_range<Rs> && ...)));

    template<input_range... Views>
    requires (view<Views> && ...) && (sizeof...(Views) > 0)
    class zip_view : public view_interface<zip_view<Views...>> {
        tuple<Views...> views_; // exposition only

        // 26.7.24.3, class template zip_view::iterator
        template<bool> class iterator; // exposition only

        // 26.7.24.4, class template zip_view::sentinel
        template<bool> class sentinel; // exposition only

    public:
        zip_view() = default;
        constexpr explicit zip_view(Views... views);

        constexpr auto begin() requires (!(simple_view<Views> && ...)) {
            return iterator<false>(tuple_transform(ranges::begin, views_));
        }
        constexpr auto begin() const requires (range<const Views> && ...) {
            return iterator<true>(tuple_transform(ranges::begin, views_));
        }
    };
}
```

```

}

constexpr auto end() requires (!simple-view<Views> && ...) {
    if constexpr (!zip-is-common<Views...>) {
        return sentinel<false>(tuple-transform(ranges::end, views_));
    } else if constexpr ((random_access_range<Views> && ...)) {
        return begin() + iter_difference_t<iterator<false>>(size());
    } else {
        return iterator<false>(tuple-transform(ranges::end, views_));
    }
}

constexpr auto end() const requires (range<const Views> && ...) {
    if constexpr (!zip-is-common<const Views...>) {
        return sentinel<true>(tuple-transform(ranges::end, views_));
    } else if constexpr ((random_access_range<const Views> && ...)) {
        return begin() + iter_difference_t<iterator<true>>(size());
    } else {
        return iterator<true>(tuple-transform(ranges::end, views_));
    }
}

constexpr auto size() requires (sized_range<Views> && ...);
constexpr auto size() const requires (sized_range<const Views> && ...);
};

template<class... Rs>
    zip_view(Rs&&...) -> zip_view<views::all_t<Rs>...>;
}

```

Two `zip_view` objects have the same underlying sequence if and only if the corresponding elements of `views_` are equal (18.2) and have the same underlying sequence.

NOTE In particular, comparison of iterators obtained from `zip_view` objects that do not have the same underlying sequence is not required to produce meaningful results (25.3.4.11).

```
constexpr explicit zip_view(Views... views_);
```

Effects: Initializes `views_` with `std::move(views)...`

```
constexpr auto size() requires (sized_range<Views> && ...);
constexpr auto size() const requires (sized_range<const Views> && ...);
```

Effects: Equivalent to:

```

return apply([](auto... sizes) {
    using CT = make_unsigned_like_t<common_type_t<decltype(sizes)...>>;
    return ranges::min({CT(sizes)...});
}, tuple-transform(ranges::size, views_));

```

26.7.24.3 Class template `zip_view::iterator`

[range.zip.iterator]

```

namespace std::ranges {
    template<bool Const, class... Views>
        concept all-random-access = // exposition only
            (random_access_range<maybe-const<Const, Views>> && ...);
    template<bool Const, class... Views>
        concept all-bidirectional = // exposition only
            (bidirectional_range<maybe-const<Const, Views>> && ...);
    template<bool Const, class... Views>
        concept all-forward = // exposition only
            (forward_range<maybe-const<Const, Views>> && ...);

    template<input_range... Views>
        requires (view<Views> && ...) && (sizeof...(Views) > 0)
    template<bool Const>
        class zip_view<Views...>::iterator {
            tuple<iterator_t<maybe-const<Const, Views>>...> current_; // exposition only

```

```

constexpr explicit iterator(tuple<iterator_t<maybe-const<Const, Views>>...>);
                                                                    // exposition only
public:
    using iterator_category = input_iterator_tag;                      // not always present
    using iterator_concept = see below;
    using value_type = tuple<range_value_t<maybe-const<Const, Views>>...>;
    using difference_type = common_type_t<range_difference_t<maybe-const<Const, Views>>...>;

    iterator() = default;
    constexpr iterator(iterator<!Const> i)
        requires Const && (convertible_to<iterator_t<Views>, iterator_t<const Views>> && ...);

    constexpr auto operator*() const;
    constexpr iterator& operator++();
    constexpr void operator++(int);
    constexpr iterator operator++(int) requires all-forward<Const, Views...>;

    constexpr iterator& operator--() requires all-bidirectional<Const, Views...>;
    constexpr iterator operator--(int) requires all-bidirectional<Const, Views...>;

    constexpr iterator& operator+=(difference_type x)
        requires all-random-access<Const, Views...>;
    constexpr iterator& operator-=(difference_type x)
        requires all-random-access<Const, Views...>;

    constexpr auto operator[](difference_type n) const
        requires all-random-access<Const, Views...>;

    friend constexpr bool operator==(const iterator& x, const iterator& y)
        requires (equality_comparable<iterator_t<maybe-const<Const, Views>>> && ...);

    friend constexpr auto operator<=>(const iterator& x, const iterator& y)
        requires all-random-access<Const, Views...>;

    friend constexpr iterator operator+(const iterator& i, difference_type n)
        requires all-random-access<Const, Views...>;
    friend constexpr iterator operator-(difference_type n, const iterator& i)
        requires all-random-access<Const, Views...>;
    friend constexpr iterator operator-(const iterator& i, difference_type n)
        requires all-random-access<Const, Views...>;
    friend constexpr difference_type operator-(const iterator& x, const iterator& y)
        requires (sized_sentinel_for<iterator_t<maybe-const<Const, Views>>,
            iterator_t<maybe-const<Const, Views>>> && ...);

    friend constexpr auto iter_move(const iterator& i) noexcept(see below);

    friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept(see below)
        requires (indirectly_swappable<iterator_t<maybe-const<Const, Views>>> && ...);
};
}

```

iterator::iterator_concept is defined as follows:

- If *all-random-access*<Const, Views...> is modeled, then *iterator_concept* denotes *random_access_iterator_tag*.
- Otherwise, if *all-bidirectional*<Const, Views...> is modeled, then *iterator_concept* denotes *bidirectional_iterator_tag*.
- Otherwise, if *all-forward*<Const, Views...> is modeled, then *iterator_concept* denotes *forward_iterator_tag*.
- Otherwise, *iterator_concept* denotes *input_iterator_tag*.

iterator::iterator_category is present if and only if *all-forward*<Const, Views...> is modeled.

If the invocation of any non-const member function of *iterator* exits via an exception, the iterator acquires a singular value.

```
constexpr explicit iterator(tuple<iterator_t<maybe-const<Const, Views>>...> current);
```

Effects: Initializes *current_* with `std::move(current)`.

```
constexpr iterator(iterator<!Const> i)
```

```
requires Const && (convertible_to<iterator_t<Views>, iterator_t<const Views>> && ...);
```

Effects: Initializes *current_* with `std::move(i.current_)`.

```
constexpr auto operator*() const;
```

Effects: Equivalent to:

```
return tuple-transform([](auto& i) -> decltype(auto) { return *i; }, current_);
```

```
constexpr iterator& operator++();
```

Effects: Equivalent to:

```
tuple-for-each([](auto& i) { ++i; }, current_);
return *this;
```

```
constexpr void operator++(int);
```

Effects: Equivalent to `++*this`.

```
constexpr iterator operator++(int) requires all-forward<Const, Views...>;
```

Effects: Equivalent to:

```
auto tmp = *this;
++*this;
return tmp;
```

```
constexpr iterator& operator--() requires all-bidirectional<Const, Views...>;
```

Effects: Equivalent to:

```
tuple-for-each([](auto& i) { --i; }, current_);
return *this;
```

```
constexpr iterator operator--(int) requires all-bidirectional<Const, Views...>;
```

Effects: Equivalent to:

```
auto tmp = *this;
--*this;
return tmp;
```

```
constexpr iterator& operator+=(difference_type x)
```

```
requires all-random-access<Const, Views...>;
```

Effects: Equivalent to:

```
tuple-for-each([&<class I>(I& i) { i += iter_difference_t<I>(x); }, current_);
return *this;
```

```
constexpr iterator& operator-=(difference_type x)
```

```
requires all-random-access<Const, Views...>;
```

Effects: Equivalent to:

```
tuple-for-each([&<class I>(I& i) { i -= iter_difference_t<I>(x); }, current_);
return *this;
```

```
constexpr auto operator[](difference_type n) const
```

```
requires all-random-access<Const, Views...>;
```

Effects: Equivalent to:

```
return tuple-transform([&<class I>(I& i) -> decltype(auto) {
    return i[iter_difference_t<I>(n)];
}, current_);
```

```
friend constexpr bool operator==(const iterator& x, const iterator& y)
    requires (equality_comparable<iterator_t<maybe-const<Const, Views>>> && ...);
```

Returns:

- $x.current\_ == y.current\_$ if *all-bidirectional*<Const, Views...> is true.
 - Otherwise, true if there exists an integer $0 \leq i < \text{sizeof}...(Views)$ such that $\text{bool}(\text{std}::\text{get}<i>(x.current\_)) == \text{std}::\text{get}<i>(y.current\_)$ is true.
- NOTE This allows *zip_view* to model *common_range* when all constituent views model *common_range*.
- Otherwise, false.

```
friend constexpr auto operator<=(const iterator& x, const iterator& y)
    requires all-random-access<Const, Views...>;
```

Returns: $x.current\_ <= y.current\_$.

```
friend constexpr iterator operator+(const iterator& i, difference_type n)
    requires all-random-access<Const, Views...>;
friend constexpr iterator operator+(difference_type n, const iterator& i)
    requires all-random-access<Const, Views...>;
```

Effects: Equivalent to:

```
auto r = i;
r += n;
return r;
```

```
friend constexpr iterator operator-(const iterator& i, difference_type n)
    requires all-random-access<Const, Views...>;
```

Effects: Equivalent to:

```
auto r = i;
r -= n;
return r;
```

```
friend constexpr difference_type operator-(const iterator& x, const iterator& y)
    requires (sized_sentinel_for<iterator_t<maybe-const<Const, Views>>,
        iterator_t<maybe-const<Const, Views>>> && ...);
```

Let $DIST(i)$ be $\text{difference\_type}(\text{std}::\text{get}<i>(x.current\_)) - \text{std}::\text{get}<i>(y.current\_)$.

Returns: The value with the smallest absolute value among $DIST(n)$ for all integers $0 \leq n < \text{sizeof}...(Views)$.

```
friend constexpr auto iter_move(const iterator& i) noexcept(see below);
```

Effects: Equivalent to:

```
return tuple_transform(ranges::iter_move, i.current_);
```

Remarks: The exception specification is equivalent to:

```
(noexcept(ranges::iter_move(declval<const iterator_t<maybe-const<Const,
    Views>>> && ...)) && ...)) &&
(is_nothrow_move_constructible_v<range_rvalue_reference_t<maybe-const<Const,
    Views>>> && ...))
```

```
friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept(see below)
    requires (indirectly_swappable<iterator_t<maybe-const<Const, Views>>> && ...);
```

Effects: For every integer $0 \leq i < \text{sizeof}...(Views)$, performs:

```
ranges::iter_swap(std::get<i>(l.current_), std::get<i>(r.current_))
```

Remarks: The exception specification is equivalent to the logical AND of the following expressions:

```
noexcept(ranges::iter_swap(std::get<i>(l.current_), std::get<i>(r.current_)))
```

for every integer $0 \leq i < \text{sizeof}...(Views)$.

26.7.24.4 Class template `zip_view::sentinel`

[range.zip.sentinel]

```

namespace std::ranges {
    template<input_range... Views>
        requires (view<Views> && ...) && (sizeof...(Views) > 0)

            requires (sized_sentinel_for<sentinel_t<maybe-const<Const, Views>>,
                iterator_t<maybe-const<OtherConst, Views>>> && ...)
        friend constexpr common_type_t<range_difference_t<maybe-const<OtherConst, Views>>...>
            operator-(const iterator<OtherConst>& x, const sentinel& y);

        template<bool OtherConst>
            requires (sized_sentinel_for<sentinel_t<maybe-const<Const, Views>>,
                iterator_t<maybe-const<OtherConst, Views>>> && ...)
        friend constexpr common_type_t<range_difference_t<maybe-const<OtherConst, Views>>...>
            operator-(const sentinel& y, const iterator<OtherConst>& x);
    };
}

constexpr explicit sentinel(tuple<sentinel_t<maybe-const<Const, Views>>...> end);

Effects: Initializes end_ with end.

constexpr sentinel(sentinel<!Const> i)
    requires Const && (convertible_to<sentinel_t<Views>, sentinel_t<const Views>> && ...);

Effects: Initializes end_ with std::move(i.end_).

template<bool OtherConst>
    requires (sentinel_for<sentinel_t<maybe-const<Const, Views>>,
        iterator_t<maybe-const<OtherConst, Views>>> && ...)
friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);

Returns: true if there exists an integer  $0 \leq i < \text{sizeof}...(Views)$  such that bool(std::get<i>(x.current_) == std::get<i>(y.end_)) is true. Otherwise, false.

template<bool OtherConst>
    requires (sized_sentinel_for<sentinel_t<maybe-const<Const, Views>>,
        iterator_t<maybe-const<OtherConst, Views>>> && ...)
friend constexpr common_type_t<range_difference_t<maybe-const<OtherConst, Views>>...>
    operator-(const iterator<OtherConst>& x, const sentinel& y);

    Let D be the return type. Let  $DIST(i)$  be  $D(\text{std::get}<i>(x.current_) - \text{std::get}<i>(y.end_))$ .

Returns: The value with the smallest absolute value among  $DIST(n)$  for all integers  $0 \leq n < \text{sizeof}...(Views)$ .

template<bool OtherConst>
    requires (sized_sentinel_for<sentinel_t<maybe-const<Const, Views>>,
        iterator_t<maybe-const<OtherConst, Views>>> && ...)
friend constexpr common_type_t<range_difference_t<maybe-const<OtherConst, Views>>...>
    operator-(const sentinel& y, const iterator<OtherConst>& x);

Effects: Equivalent to return -(x - y);

```

26.7.25 Zip transform view**[range.zip.transform]****26.7.25.1 Overview****[range.zip.transform.overview]**

`zip_transform_view` takes an invocable object and any number of views and produces a view whose M^{th} element is the result of applying the invocable object to the M^{th} elements of all views.

The name `views::zip_transform` denotes a customization point object (16.3.3.3.5). Let `F` be a subexpression, and let `Es...` be a pack of subexpressions.

- If `Es` is an empty pack, let `FD` be `decay_t<decltype((F))>`.
 - If `move_constructible<FD> && regular_invocable<FD&>` is false, or if `decay_t<invoke_result_t<FD&>>` is not an object type, `views::zip_transform(F, Es...)` is ill-formed.
 - Otherwise, the expression `views::zip_transform(F, Es...)` is expression-equivalent to `((void)F, auto(v1 : views::empty<decay_t<invoke_result_t<FD&>>>))`
- Otherwise, the expression `views::zip_transform(F, Es...)` is expression-equivalent to `zip_transform_view(F, Es...)`.

EXAMPLE

```
vector v1 = {1, 2};
vector v2 = {4, 5, 6};

for (auto i : views::zip_transform(plus(), v1, v2)) {
    cout << i << ' ';    // prints 5 7
}
```

26.7.25.2 Class template `zip_transform_view`**[range.zip.transform.view]**

```

}

constexpr explicit zip_transform_view(F fun, Views... views);

```

Effects: Initializes *fun_* with `std::move(fun)` and *zip_* with `std::move(views)...`

26.7.25.3 Class template `zip_transform_view::iterator` [range.zip.transform.iterator]

```

namespace std::ranges {
    template<move_constructible F, input_range... Views>
        requires (view<Views> && ...) && (sizeof...(Views) > 0) && is_object_v<F> &&
            regular_invocable<F&, range_reference_t<Views>...> &&
            can_reference<invoke_result_t<F&, range_reference_t<Views>...>>
        template<bool Const>
        class zip_transform_view<F, Views...>::iterator {
            using Parent = maybe_const<Const, zip_transform_view>; // exposition only
            using Base = maybe_const<Const, InnerView>; // exposition only
            Parent* parent_ = nullptr; // exposition only
            ziperator<Const> inner_; // exposition only

            constexpr iterator(Parent& parent, ziperator<Const> inner); // exposition only

        public:
            using iterator_category = see below; // not always present
            using iterator_concept = typename ziperator<Const>::iterator_concept;
            using value_type =
                remove_cvref_t<invoke_result_t<maybe_const<Const, F>&,
                    range_reference_t<maybe_const<Const, Views>>...>>;
            using difference_type = range_difference_t<Base>;

            iterator() = default;
            constexpr iterator(iterator<!Const> i)
                requires Const && convertible_to<ziperator<false>, ziperator<Const>>;

            constexpr decltype(auto) operator*() const noexcept(see below);
            constexpr iterator& operator++();
            constexpr void operator++(int);
            constexpr iterator operator++(int) requires forward_range<Base>;

```

```

constexpr iterator& operator--() requires bidirectional_range<Base>;
constexpr iterator operator--(int) requires bidirectional_range<Base>;

constexpr iterator& operator+=(difference_type x) requires random_access_range<Base>;
constexpr iterator& operator-=(difference_type x) requires random_access_range<Base>;

constexpr decltype(auto) operator[](difference_type n) const
    requires random_access_range<Base>;

friend constexpr bool operator==(const iterator& x, const iterator& y)
    requires equality_comparable<ziperator<Const>>;

friend constexpr auto operator<=>(const iterator& x, const iterator& y)
    requires random_access_range<Base>;

friend constexpr iterator operator+(const iterator& i, difference_type n)
    requires random_access_range<Base>;
friend constexpr iterator operator+(difference_type n, const iterator& i)
    requires random_access_range<Base>;
friend constexpr iterator operator-(const iterator& i, difference_type n)
    requires random_access_range<Base>;
friend constexpr difference_type operator-(const iterator& x, const iterator& y)
    requires sized_sentinel_for<ziperator<Const>, ziperator<Const>>;
};
}

```

The member *typedef-name* `iterator::iterator_category` is defined if and only if *Base* models `forward_range`. In that case, `iterator::iterator_category` is defined as follows:

- If
 - `invoke_result_t<maybe_const<Const, F>&, range_reference_t<maybe_const<Const, Views>>...>` is not a reference, `iterator_category` denotes `input_iterator_tag`.
- Otherwise, let *Cs* denote the pack of types `iterator_traits<iterator_t<maybe_const<Const, Views>>>::iterator_category...`
 - If `(derived_from<Cs, random_access_iterator_tag> && ...)` is true, `iterator_category` denotes `random_access_iterator_tag`.
 - Otherwise, if `(derived_from<Cs, bidirectional_iterator_tag> && ...)` is true, `iterator_category` denotes `bidirectional_iterator_tag`.
 - Otherwise, if `(derived_from<Cs, forward_iterator_tag> && ...)` is true, `iterator_category` denotes `forward_iterator_tag`.
 - Otherwise, `iterator_category` denotes `input_iterator_tag`.

```
constexpr iterator(Parent& parent, ziperator<Const> inner);
```

Effects: Initializes `parent_` with `addressof(parent)` and `inner_` with `std::move(inner)`.

```
constexpr iterator(iterator<!Const> i)
    requires Const && convertible_to<ziperator<false>, ziperator<Const>>;
```

Effects: Initializes `parent_` with `i.parent_` and `inner_` with `std::move(i.inner_)`.

```
constexpr decltype(auto) operator*() const noexcept(see below);
```

Effects: Equivalent to:

```

return apply([&](const auto&... iters) -> decltype(auto) {
    return invoke(*parent_->fun_, *iters...);
}, inner_.current_);

```

Remarks: Let *Is* be the pack 0, 1, ..., `(sizeof...(Views)-1)`. The exception specification is equivalent to: `noexcept(invoke(*parent_->fun_, *std::get<Is>(inner_.current_)...))`.

```
constexpr iterator& operator++();
```

Effects: Equivalent to:

```

    ++inner_;
    return *this;

constexpr void operator++(int);
Effects: Equivalent to: ++*this.

constexpr iterator operator++(int) requires forward_range<Base>;
Effects: Equivalent to:
    auto tmp = *this;
    ++*this;
    return tmp;

constexpr iterator& operator--() requires bidirectional_range<Base>;
Effects: Equivalent to:
    --inner_;
    return *this;

constexpr iterator operator--(int) requires bidirectional_range<Base>;
Effects: Equivalent to:
    auto tmp = *this;
    --*this;
    return tmp;

constexpr iterator& operator+=(difference_type x)
    requires random_access_range<Base>;
Effects: Equivalent to:
    inner_ += x;
    return *this;

friend constexpr range_difference_t<maybe_const<OtherConst, InnerView>>
    operator-(const sentinel& x, const iterator<OtherConst>& y);
```

Effects: Equivalent to: return `x.inner_ - y.inner_;`

26.7.26 Adjacent view**[range.adjacent]****26.7.26.1 Overview****[range.adjacent.overview]**

`adjacent_view` takes a view and produces a view whose M^{th} element is a tuple of references to the M^{th} through $(M + N - 1)^{\text{th}}$ elements of the original view. If the original view has fewer than N elements, the resulting view is empty.

The name `views::adjacent<N>` denotes a range adaptor object (26.7.2). Given a subexpression E and a constant expression N , the expression `views::adjacent<N>(E)` is expression-equivalent to

- `((void)E, auto{views::empty<tuple<>>})` if N is equal to 0,
- otherwise, `adjacent_view<views::all_t<decltype(E)>, N>(E)`.

EXAMPLE

```
vector v = {1, 2, 3, 4};

for (auto i : v | views::adjacent<2>) {
    cout << "(" << std::get<0>(i) << ", " << std::get<1>(i) << ") "; // prints (1, 2) (2, 3) (3, 4)
}
```

Define *REPEAT*(T , N) as a pack of N types, each of which denotes the same type as T .

26.7.26.2 Class template `adjacent_view`**[range.adjacent.view]**

```
namespace std::ranges {
    template<forward_range V, size_t N>
        requires view<V> && (N > 0)
    class adjacent_view : public view_interface<adjacent_view<V, N>> {
        V base_ = V(); // exposition only

        // 26.7.26.3, class template adjacent_view::iterator
        template<bool> class iterator; // exposition only

        // 26.7.26.4, class template adjacent_view::sentinel
        template<bool> class sentinel; // exposition only

        struct as-sentinel{}; // exposition only

    public:
        adjacent_view() requires default_initializable<V> = default;
        constexpr explicit adjacent_view(V base_);

        constexpr V base() const & requires copy_constructible<V> { return base_; }
        constexpr V base() && { return std::move(base_); }

        constexpr auto begin() requires (!simple-view<V>) {
            return iterator<false>(ranges::begin(base_), ranges::end(base_));
        }

        constexpr auto begin() const requires range<const V> {
            return iterator<true>(ranges::begin(base_), ranges::end(base_));
        }

        constexpr auto end() requires (!simple-view<V>) {
            if constexpr (common_range<V>) {
                return iterator<false>(as-sentinel{}, ranges::begin(base_), ranges::end(base_));
            } else {
                return sentinel<false>(ranges::end(base_));
            }
        }

        constexpr auto end() const requires range<const V> {
            if constexpr (common_range<const V>) {
                return iterator<true>(as-sentinel{}, ranges::begin(base_), ranges::end(base_));
            } else {
                return sentinel<true>(ranges::end(base_));
            }
        }
    };
}
```

```

    }
}

constexpr auto size() requires sized_range<V>;
constexpr auto size() const requires sized_range<const V>;
};
}

```

```
constexpr explicit adjacent_view(V base);
```

Effects: Initializes *base_* with `std::move(base)`.

```
constexpr auto size() requires sized_range<V>;
constexpr auto size() const requires sized_range<const V>;
```

Effects: Equivalent to:

```

using ST = decltype(ranges::size(base_));
using CT = common_type_t<ST, size_t>;
auto sz = static_cast<CT>(ranges::size(base_));
sz -= std::min<CT>(sz, N - 1);
return static_cast<ST>(sz);

```

26.7.26.3 Class template `adjacent_view::iterator`

[range.adjacent.iterator]

```

namespace std::ranges {
    template<forward_range V, size_t N>
        requires view<V> && (N > 0)
    template<bool Const>
    class adjacent_view<V, N>::iterator {
        using Base = maybe_const<Const, V>;                                // exposition only
        array<iterator_t<Base>, N> current_ = array<iterator_t<Base>, N>();    // exposition only
        constexpr iterator(iterator_t<Base> first, sentinel_t<Base> last);    // exposition only
        constexpr iterator(as-sentinel, iterator_t<Base> first, iterator_t<Base> last);    // exposition only

    public:
        using iterator_category = input_iterator_tag;
        using iterator_concept = see below;
        using value_type = tuple<REPEAT(range_value_t<Base>, N)...>;
        using difference_type = range_difference_t<Base>;

        iterator() = default;
        constexpr iterator(iterator<!Const> i)
            requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;

        constexpr auto operator*() const;
        constexpr iterator& operator++();
        constexpr iterator operator++(int);

        constexpr iterator& operator--() requires bidirectional_range<Base>;
        constexpr iterator operator--(int) requires bidirectional_range<Base>;

        constexpr iterator& operator+=(difference_type x)
            requires random_access_range<Base>;
        constexpr iterator& operator-=(difference_type x)
            requires random_access_range<Base>;

        constexpr auto operator[](difference_type n) const
            requires random_access_range<Base>;

        friend constexpr bool operator==(const iterator& x, const iterator& y);
        friend constexpr bool operator<(const iterator& x, const iterator& y)
            requires random_access_range<Base>;
        friend constexpr bool operator>(const iterator& x, const iterator& y)
            requires random_access_range<Base>;
        friend constexpr bool operator<=(const iterator& x, const iterator& y)
            requires random_access_range<Base>;
    };
}

```

```

friend constexpr bool operator>=(const iterator& x, const iterator& y)
    requires random_access_range<Base>;
friend constexpr auto operator<=>(const iterator& x, const iterator& y)
    requires random_access_range<Base> &&
        three_way_comparable<iterator_t<Base>>;

friend constexpr iterator operator+(const iterator& i, difference_type n)
    requires random_access_range<Base>;
friend constexpr iterator operator+(difference_type n, const iterator& i)
    requires random_access_range<Base>;
friend constexpr iterator operator-(const iterator& i, difference_type n)
    requires random_access_range<Base>;
friend constexpr difference_type operator-(const iterator& x, const iterator& y)
    requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;

friend constexpr auto iter_move(const iterator& i) noexcept(see below);
friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept(see below)
    requires indirectly_swappable<iterator_t<Base>>;
};
}

```

iterator::iterator_concept is defined as follows:

- If *Base* models *random_access_range*, then *iterator_concept* denotes *random_access_iterator_tag*.
- Otherwise, if *Base* models *bidirectional_range*, then *iterator_concept* denotes *bidirectional_iterator_tag*.
- Otherwise, *iterator_concept* denotes *forward_iterator_tag*.

If the invocation of any non-const member function of *iterator* exits via an exception, the *iterator* acquires a singular value.

```
constexpr iterator(iterator_t<Base> first, sentinel_t<Base> last);
```

Postconditions: *current_[0]* == *first* is true, and for every integer $1 \leq i < N$, *current_[i]* == *ranges::next(current_[i-1], 1, last)* is true.

```
constexpr iterator(as-sentinel, iterator_t<Base> first, iterator_t<Base> last);
```

Postconditions: If *Base* does not model *bidirectional_range*, each element of *current_* is equal to *last*. Otherwise, *current_[N-1]* == *last* is true, and for every integer $0 \leq i < (N-1)$, *current_[i]* == *ranges::prev(current_[i+1], 1, first)* is true.

```
constexpr iterator(iterator& i)
    requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;
```

Effects: Initializes each element of *current_* with the corresponding element of *i*. *current_* as an xvalue.

```
constexpr auto operator*() const;
```

Effects: Equivalent to:

```
return tuple-transform([], (auto& i) -> decltype(auto) { return *i; }, current_);
```

```
constexpr iterator& operator++();
```

Preconditions: *current_.back()* is incrementable.

Postconditions: Each element of *current_* is equal to *ranges::next(i)*, where *i* is the value of that element before the call.

Returns: **this*.

```
constexpr iterator operator++(int);
```

Effects: Equivalent to:

```
auto tmp = *this;
++*this;
```

```

    return tmp;

constexpr iterator& operator--() requires bidirectional_range<Base>;
    Preconditions: current_.front() is decrementable.
    Postconditions: Each element of current_ is equal to ranges::prev(i), where i is the value of that
    element before the call.
    Returns: *this.

constexpr iterator operator--(int) requires bidirectional_range<Base>;
    Effects: Equivalent to:
        auto tmp = *this;
        --*this;
        return tmp;

constexpr iterator& operator+=(difference_type x)
    requires random_access_range<Base>;
    Preconditions: current_.back() + x has well-defined behavior.
    Postconditions: Each element of current_ is equal to i + x, where i is the value of that element
    before the call.
    Returns: *this.

constexpr iterator& operator-=(difference_type x)
    requires random_access_range<Base>;
    Preconditions: current_.front() - x has well-defined behavior.
    Postconditions: Each element of current_ is equal to i - x, where i is the value of that element
    before the call.
    Returns: *this.

constexpr auto operator[](difference_type n) const
    requires random_access_range<Base>;
    Effects: Equivalent to:
        return tuple-transform([&](auto& i) -> decltype(auto) { return i[n]; }, current_);

friend constexpr bool operator==(const iterator& x, const iterator& y);
    Returns: x.current_.back() == y.current_.back().

friend constexpr bool operator<(const iterator& x, const iterator& y)
    requires random_access_range<Base>;
    Returns: x.current_.back() < y.current_.back().

friend constexpr bool operator>(const iterator& x, const iterator& y)
    requires random_access_range<Base>;
    Effects: Equivalent to: return y < x;

friend constexpr bool operator<=(const iterator& x, const iterator& y)
    requires random_access_range<Base>;
    Effects: Equivalent to: return !(y < x);

friend constexpr bool operator>=(const iterator& x, const iterator& y)
    requires random_access_range<Base>;
    Effects: Equivalent to: return !(x < y);

friend constexpr auto operator<=>(const iterator& x, const iterator& y)
    requires random_access_range<Base> &&
    three_way_comparable<iterator_t<Base>>;
    Returns: x.current_.back() <=> y.current_.back().

```

```
friend constexpr iterator operator+(const iterator& i, difference_type n)
    requires random_access_range<Base>;
friend constexpr iterator operator+(difference_type n, const iterator& i)
    requires random_access_range<Base>;
```

Effects: Equivalent to:

```
auto r = i;
r += n;
return r;
```

```
friend constexpr iterator operator-(const iterator& i, difference_type n)
    requires random_access_range<Base>;
```

Effects: Equivalent to:

```
auto r = i;
r -= n;
return r;
```

```
friend constexpr difference_type operator-(const iterator& x, const iterator& y)
    requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;
```

Effects: Equivalent to: `return x.current_.back() - y.current_.back();`

```
friend constexpr auto iter_move(const iterator& i) noexcept(see below);
```

Effects: Equivalent to: `return tuple_transform(ranges::iter_move, i.current_);`

Remarks: The exception specification is equivalent to:

```
noexcept(ranges::iter_move(declval<const iterator_t<Base>&>()) &&
    is_nothrow_move_constructible_v<range_rvalue_reference_t<Base>>
```

```
friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept(see below)
    requires indirectly_swappable<iterator_t<Base>>;
```

Preconditions: None of the iterators in `l.current_` is equal to an iterator in `r.current_`.

Effects: For every integer $0 \leq i < N$, performs `ranges::iter_swap(l.current_[i], r.current_[i])`.

Remarks: The exception specification is equivalent to:

```
noexcept(ranges::iter_swap(declval<iterator_t<Base>>(), declval<iterator_t<Base>>()))
```

26.7.26.4 Class template `adjacent_view::sentinel`

[range.adjacent.sentinel]

```
namespace std::ranges {
    template<forward_range V, size_t N>
        requires view<V> && (N > 0)
    template<bool Const>
    class adjacent_view<V, N>::sentinel {
        using Base = maybe_const<Const, V>; // exposition only
        sentinel_t<Base> end_ = sentinel_t<Base>(); // exposition only
        constexpr explicit sentinel(sentinel_t<Base> end); // exposition only

    public:
        sentinel() = default;
        constexpr sentinel(sentinel<!Const> i)
            requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;

        template<bool OtherConst>
            requires sentinel_for<sentinel_t<Base>, iterator_t<maybe_const<OtherConst, V>>>
        friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);

        template<bool OtherConst>
            requires sized_sentinel_for<sentinel_t<Base>, iterator_t<maybe_const<OtherConst, V>>>
        friend constexpr range_difference_t<maybe_const<OtherConst, V>>
            operator-(const iterator<OtherConst>& x, const sentinel& y);
```

```

template<bool OtherConst>
    requires sized_sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
    friend constexpr range_difference_t<maybe-const<OtherConst, V>>
        operator-(const sentinel& y, const iterator<OtherConst>& x);
};
}

constexpr explicit sentinel(sentinel_t<Base> end);

Effects: Initializes end_ with end.

constexpr sentinel(sentinel_t<!Const> i)
    requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;

Effects: Initializes end_ with std::move(i.end_).

template<bool OtherConst>
    requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
    friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);

Effects: Equivalent to: return x.current_.back() == y.end_;

template<bool OtherConst>
    requires sized_sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
    friend constexpr range_difference_t<maybe-const<OtherConst, V>>
        operator-(const iterator<OtherConst>& x, const sentinel& y);

Effects: Equivalent to: return x.current_.back() - y.end_;

template<bool OtherConst>
    requires sized_sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
    friend constexpr range_difference_t<maybe-const<OtherConst, V>>
        operator-(const sentinel& y, const iterator<OtherConst>& x);

Effects: Equivalent to: return y.end_ - x.current_.back();

```

26.7.27 Adjacent transform view [range.adjacent.transform]

26.7.27.1 Overview [range.adjacent.transform.overview]

adjacent_transform_view takes an invocable object and a view and produces a view whose M^{th} element is the result of applying the invocable object to the M^{th} through $(M + N - 1)^{\text{th}}$ elements of the original view. If the original view has fewer than N elements, the resulting view is empty.

The name *views::adjacent_transform*<*N*> denotes a range adaptor object (26.7.2). Given subexpressions *E* and *F* and a constant expression *N*:

- If *N* is equal to 0, *views::adjacent_transform*<*N*>(*E*, *F*) is expression-equivalent to *((void)E, views::zip_transform(F))*, except that the evaluations of *E* and *F* are indeterminately sequenced.
- Otherwise, the expression *views::adjacent_transform*<*N*>(*E*, *F*) is expression-equivalent to *adjacent_transform_view<views::all_t<decltype((E))>, decay_t<decltype((F))>, N>(E, F)*.

EXAMPLE

```

vector v = {1, 2, 3, 4};

for (auto i : v | views::adjacent_transform<2>(std::multiplies())) {
    cout << i << ' ';    // prints 2 6 12
}

```

26.7.27.2 Class template *adjacent_transform_view* [range.adjacent.transform.view]

```

namespace std::ranges {
    template<forward_range V, move_constructible F, size_t N>
        requires view<V> && (N > 0) && is_object_v<F> &&
            regular_invocable<F&, REPEAT(range_reference_t<V>, N)...> &&
            can_reference<invoke_result_t<F&, REPEAT(range_reference_t<V>, N)...>>
    class adjacent_transform_view : public view_interface<adjacent_transform_view<V, F, N>> {
        movable_box<F> fun_;                // exposition only
        adjacent_view<V, N> inner_;          // exposition only
    };
}

```

```

using InnerView = adjacent_view<V, N>;           // exposition only
template<bool Const>
    using inner_iterator = iterator_t<maybe-const<Const, InnerView>>;           // exposition only
template<bool Const>
    using inner_sentinel = sentinel_t<maybe-const<Const, InnerView>>;           // exposition only

// 26.7.27.3, class template adjacent_transform_view::iterator
template<bool> class iterator;           // exposition only

// 26.7.27.4, class template adjacent_transform_view::sentinel
template<bool> class sentinel;           // exposition only

public:
    adjacent_transform_view() = default;
    constexpr explicit adjacent_transform_view(V base, F fun);

    constexpr V base() const & requires copy_constructible<InnerView> { return inner_.base(); }
    constexpr V base() && { return std::move(inner_).base(); }

    constexpr auto begin() {
        return iterator<false>(*this, inner_.begin());
    }

    constexpr auto begin() const
        requires range<const InnerView> &&
        regular_invocable<const F&, REPEAT(range_reference_t<const V>, N)...> {
        return iterator<true>(*this, inner_.begin());
    }

    constexpr auto end() {
        if constexpr (common_range<InnerView>) {
            return iterator<false>(*this, inner_.end());
        } else {

            requires sized_sentinel_for<inner_iterator<Const>, inner_iterator<Const>>;
    };
}

```

The member `typedef-name iterator::iterator_category` is defined as follows:

- If `invoke_result_t<maybe-const<Const, F>&, REPEAT(range_reference_t<Base>, N)...>` is not a reference, `iterator_category` denotes `input_iterator_tag`.
- Otherwise, let `C` denote the type `iterator_traits<iterator_t<Base>>::iterator_category`.
 - If `derived_from<C, random_access_iterator_tag>` is true, `iterator_category` denotes `random_access_iterator_tag`.
 - Otherwise, if `derived_from<C, bidirectional_iterator_tag>` is true, `iterator_category` denotes `bidirectional_iterator_tag`.
 - Otherwise, if `derived_from<C, forward_iterator_tag>` is true, `iterator_category` denotes `forward_iterator_tag`.
 - Otherwise, `iterator_category` denotes `input_iterator_tag`.

```
constexpr iterator(Parent& parent, inner-iterator<Const> inner);
```

Effects: Initializes `parent_` with `addressof(parent)` and `inner_` with `std::move(inner)`.

```
constexpr iterator(iterator<!Const> i)
```

requires `Const && convertible_to<inner-iterator<false>, inner-iterator<Const>>`;

Effects: Initializes `parent_` with `i.parent_` and `inner_` with `std::move(i.inner_)`.

```
constexpr decltype(auto) operator*() const noexcept(see below);
```

Effects: Equivalent to:

```
return apply([&](const auto&... iters) -> decltype(auto) {

template<bool OtherConst>
    requires sized_sentinel_for<inner-sentinel<Const>, inner-iterator<OtherConst>>
friend constexpr range_difference_t<maybe-const<OtherConst, InnerView>>
    operator-(const sentinel& x, const iterator<OtherConst>& y);
    Effects: Equivalent to return x.inner_ - y.inner_;

```

26.7.28 Chunk view

[range.chunk]

26.7.28.1 Overview

[range.chunk.overview]

`chunk_view` takes a view and a number N and produces a range of views that are N -sized non-overlapping successive chunks of the elements of the original view, in order. The last view in the range can have fewer than N elements.

The name `views::chunk` denotes a range adaptor object (26.7.2). Given subexpressions E and N , the expression `views::chunk(E, N)` is expression-equivalent to `chunk_view(E, N)`.

EXAMPLE

```

vector v = {1, 2, 3, 4, 5};

for (auto r : v | views::chunk(2)) {
    cout << '[';
    auto sep = "";
    for (auto i : r) {
        cout << sep << i;
        sep = ", ";
    }
    cout << "]" << " ";
}
// The above prints [1, 2] [3, 4] [5]

```

26.7.28.2 Class template `chunk_view` for input ranges

[range.chunk.view.input]

```

namespace std::ranges {
    template<class I>
    constexpr I div-ceil(I num, I denom) { // exposition only
        I r = num / denom;
        if (num % denom)
            ++r;
        return r;
    }

    template<view V>
    requires input_range<V>
    class chunk_view : public view_interface<chunk_view<V>> {
        V base_; // exposition only
        range_difference_t<V> n_; // exposition only
        range_difference_t<V> remainder_ = 0; // exposition only

        non-propagating_cache<iterator_t<V>> current_; // exposition only

        // 26.7.28.3, class chunk_view::outer-iterator

friend constexpr difference_type operator-(const iterator& x, default_sentinel_t y)
    requires sized_sentinel_for<sentinel_t<Base>, iterator_t<Base>>;
```

Effects: Equivalent to: `return -(y - x);`

26.7.29 Slide view

[range.slide]

26.7.29.1 Overview

[range.slide.overview]

`slide_view` takes a view and a number N and produces a view whose M^{th} element is a view over the M^{th} through $(M + N - 1)^{\text{th}}$ elements of the original view. If the original view has fewer than N elements, the resulting view is empty.

The name `views::slide` denotes a range adaptor object (26.7.2). Given subexpressions E and N , the expression `views::slide(E, N)` is expression-equivalent to `slide_view(E, N)`.

EXAMPLE

```
vector v = {1, 2, 3, 4};

for (auto i : v | views::slide(2)) {
    cout << '[' << i[0] << ", " << i[1] << " ] ";           // prints [1, 2] [2, 3] [3, 4]
}
```

26.7.29.2 Class template `slide_view`

[range.slide.view]

```
namespace std::ranges {
    template<class V>
        concept slide_caches_nothing = random_access_range<V> && sized_range<V>;           // exposition only

    constexpr auto begin()
        requires (!simple-view<V> && slide-caches-nothing<const V>);
    constexpr auto begin() const requires slide-caches-nothing<const V>;

    constexpr auto end()
        requires (!simple-view<V> && slide-caches-nothing<const V>);
    constexpr auto end() const requires slide-caches-nothing<const V>;

    constexpr auto size() requires sized_range<V>;
    constexpr auto size() const requires sized_range<const V>;
};

template<class R>
    slide_view(R&&, range_difference_t<R>) -> slide_view<views::all_t<R>>;
}

constexpr explicit slide_view(V base, range_difference_t<V> n);
    Preconditions:  $n > 0$  is true.
    Effects: Initializes base_ with std::move(base) and n_ with n.

constexpr auto begin()
    requires (!simple-view<V> && slide-caches-nothing<const V>);
    Returns:
        — If V models slide-caches-first,
            iterator<false>(ranges::begin(base_),
                ranges::next(ranges::begin(base_), n_ - 1, ranges::end(base_)), n_)
        — Otherwise, iterator<false>(ranges::begin(base_), n_).
    Remarks: In order to provide the amortized constant-time complexity required by the range concept,
    this function caches the result within the slide_view for use on subsequent calls when V models
    slide-caches-first.

constexpr auto begin() const requires slide-caches-nothing<const V>;
    Returns: iterator<true>(ranges::begin(base_), n_).

constexpr auto end()
    requires (!simple-view<V> && slide-caches-nothing<const V>);
    Returns:
        — If V models slide-caches-nothing,
            iterator<false>(ranges::begin(base_) + range_difference_t<V>(size()), n_)
        — Otherwise, if V models slide-caches-last,
            iterator<false>(ranges::prev(ranges::end(base_), n_ - 1, ranges::begin(base_)), n_)
        — Otherwise, if V models common_range,
            iterator<false>(ranges::end(base_), ranges::end(base_), n_)
        — Otherwise, sentinel (ranges::end(base_)).

```

Remarks: In order to provide the amortized constant-time complexity required by the `range` concept, this function caches the result within the `slide_view` for use on subsequent calls when `V` models `slide-caches-last`.

`constexpr auto end()` `const` requires `slide-caches-nothing`<const `V`>;

Returns: `begin()` + `range_difference_t`<const `V`>(size()).

`constexpr auto size()` requires `sized_range`<`V`>;

`constexpr auto size()` `const` requires `sized_range`<const `V`>;

Effects: Equivalent to:

```
auto sz = ranges::distance(base_) - n_ + 1;
if (sz < 0) sz = 0;
return to-unsigned-like(sz);
```

26.7.29.3 Class template `slide_view::iterator`

[`range.slide.iterator`]

```
namespace std::ranges {
    template<forward_range V>
        requires view<V>
    template<bool Const>
    class slide_view<V>::iterator {
        using Base = maybe-const<Const, V>;           // exposition only
        iterator_t<Base> current_ = iterator_t<Base>(); // exposition only
        iterator_t<Base> last_ele_ = iterator_t<Base>(); // exposition only,
                                                    // present only if Base models slide-caches-first
        range_difference_t<Base> n_ = 0;               // exposition only

        constexpr iterator(iterator_t<Base> current, range_difference_t<Base> n) // exposition only
            requires (!slide-caches-first<Base>);

        constexpr iterator(iterator_t<Base> current, iterator_t<Base> last_ele, // exposition only
            range_difference_t<Base> n)
            requires slide-caches-first<Base>;

    public:
        using iterator_category = input_iterator_tag;
        using iterator_concept = see below;
        using value_type = decltype(views::counted(current_, n_));
        using difference_type = range_difference_t<Base>;

        iterator() = default;
        constexpr iterator(iterator<!Const> i)
            requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;

        constexpr auto operator*() const;
        constexpr iterator& operator++();
        constexpr iterator operator++(int);

        constexpr iterator& operator--() requires bidirectional_range<Base>;
        constexpr iterator operator--(int) requires bidirectional_range<Base>;

        constexpr iterator& operator+=(difference_type x)
            requires random_access_range<Base>;
        constexpr iterator& operator-=(difference_type x)
            requires random_access_range<Base>;

        constexpr auto operator[](difference_type n) const
            requires random_access_range<Base>;

        friend constexpr bool operator==(const iterator& x, const iterator& y);

        friend constexpr bool operator<(const iterator& x, const iterator& y)
            requires random_access_range<Base>;
```

```

friend constexpr bool operator>(const iterator& x, const iterator& y)
    requires random_access_range<Base>;
friend constexpr bool operator<=(const iterator& x, const iterator& y)
    requires random_access_range<Base>;
friend constexpr bool operator>=(const iterator& x, const iterator& y)
    requires random_access_range<Base>;
friend constexpr auto operator<=>(const iterator& x, const iterator& y)
    requires random_access_range<Base> &&
        three_way_comparable<iterator_t<Base>>;

friend constexpr iterator operator+(const iterator& i, difference_type n)
    requires random_access_range<Base>;
friend constexpr iterator operator+(difference_type n, const iterator& i)
    requires random_access_range<Base>;
friend constexpr iterator operator-(const iterator& i, difference_type n)
    requires random_access_range<Base>;
friend constexpr difference_type operator-(const iterator& x, const iterator& y)
    requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;
};
}

```

iterator::*iterator_concept* is defined as follows:

- If *Base* models *random_access_range*, then *iterator_concept* denotes *random_access_iterator_tag*.
- Otherwise, if *Base* models *bidirectional_range*, then *iterator_concept* denotes *bidirectional_iterator_tag*.
- Otherwise, *iterator_concept* denotes *forward_iterator_tag*.

If the invocation of any non-const member function of *iterator* exits via an exception, the *iterator* acquires a singular value.

```

constexpr iterator(iterator_t<Base> current, range_difference_t<Base> n)
    requires (!slide-caches-first<Base>);

```

Effects: Initializes *current_* with *current* and *n_* with *n*.

```

constexpr iterator(iterator_t<Base> current, iterator_t<Base> last_ele,
    range_difference_t<Base> n)
    requires slide-caches-first<Base>;

```

Effects: Initializes *current_* with *current*, *last_ele_* with *last_ele*, and *n_* with *n*.

```

constexpr iterator(iterator<!Const> i)
    requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;

```

Effects: Initializes *current_* with `std::move(i.current_)` and *n_* with *i.n_*.

NOTE *iterator*<*true*> can only be formed when *Base* models *slide-caches-nothing*, in which case *last_ele_* is not present.

```

constexpr auto operator*() const;

```

Returns: `views::counted(current_, n_)`.

```

constexpr iterator& operator++();

```

Preconditions: *current_* and *last_ele_* (if present) are incrementable.

Postconditions: *current_* and *last_ele_* (if present) are each equal to `ranges::next(i)`, where *i* is the value of that data member before the call.

Returns: **this*.

```

constexpr iterator operator++(int);

```

Effects: Equivalent to:

```

auto tmp = *this;
++*this;
return tmp;

```

`constexpr iterator& operator--()` requires `bidirectional_range<Base>`;

Preconditions: `current_` and `last_ele_` (if present) are decrementable.

Postconditions: `current_` and `last_ele_` (if present) are each equal to `ranges::prev(i)`, where `i` is the value of that data member before the call.

Returns: `*this`.

`constexpr iterator operator--(int)` requires `bidirectional_range<Base>`;

Effects: Equivalent to:

```
auto tmp = *this;
--*this;
return tmp;
```

`constexpr iterator& operator+=(difference_type x)`
requires `random_access_range<Base>`;

Preconditions: `current_ + x` and `last_ele_ + x` (if `last_ele_` is present) have well-defined behavior.

Postconditions: `current_` and `last_ele_` (if present) are each equal to `i + x`, where `i` is the value of that data member before the call.

Returns: `*this`.

`constexpr iterator& operator-=(difference_type x)`
requires `random_access_range<Base>`;

Preconditions: `current_ - x` and `last_ele_ - x` (if `last_ele_` is present) have well-defined behavior.

Postconditions: `current_` and `last_ele_` (if present) are each equal to `i - x`, where `i` is the value of that data member before the call.

Returns: `*this`.

`constexpr auto operator[](difference_type n) const`
requires `random_access_range<Base>`;

Effects: Equivalent to: `return views::counted(current_ + n, n_);`

`friend constexpr bool operator==(const iterator& x, const iterator& y);`

Returns: If `last_ele_` is present, `x.last_ele_ == y.last_ele_`; otherwise, `x.current_ == y.current_`.

`friend constexpr bool operator<(const iterator& x, const iterator& y)`
requires `random_access_range<Base>`;

Returns: `x.current_ < y.current_`.

`friend constexpr bool operator>(const iterator& x, const iterator& y)`
requires `random_access_range<Base>`;

Effects: Equivalent to: `return y < x;`

`friend constexpr bool operator<=(const iterator& x, const iterator& y)`
requires `random_access_range<Base>`;

Effects: Equivalent to: `return !(y < x);`

`friend constexpr bool operator>=(const iterator& x, const iterator& y)`
requires `random_access_range<Base>`;

Effects: Equivalent to: `return !(x < y);`

`friend constexpr auto operator<=>(const iterator& x, const iterator& y)`
requires `random_access_range<Base> &&`
`three_way_comparable<iterator_t<Base>>`;

Returns: `x.current_ <=> y.current_`.

`friend constexpr iterator operator+(const iterator& i, difference_type n)`
requires `random_access_range<Base>`;

```
friend constexpr iterator operator+(difference_type n, const iterator& i)
    requires random_access_range<Base>;
```

Effects: Equivalent to:

```
auto r = i;
r += n;
return r;
```

```
friend constexpr iterator operator-(const iterator& i, difference_type n)
    requires random_access_range<Base>;
```

Effects: Equivalent to:

```
auto r = i;
r -= n;
return r;
```

```
friend constexpr difference_type operator-(const iterator& x, const iterator& y)
    requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;
```

Returns: If *last_ele_* is present, *x.last_ele_* - *y.last_ele_*; otherwise, *x.current_* - *y.current_*.

26.7.29.4 Class *slide_view::sentinel*

[range.slide.sentinel]

```
namespace std::ranges {
    template<forward_range V>
        requires view<V>
        class slide_view<V>::sentinel {
            sentinel_t<V> end_ = sentinel_t<V>();           // exposition only
            constexpr explicit sentinel(sentinel_t<V> end); // exposition only

        public:
            sentinel() = default;

            friend constexpr bool operator==(const iterator<false>& x, const sentinel& y);

            friend constexpr range_difference_t<V>
                operator-(const iterator<false>& x, const sentinel& y)
                    requires sized_sentinel_for<sentinel_t<V>, iterator_t<V>>;

            friend constexpr range_difference_t<V>
                operator-(const sentinel& y, const iterator<false>& x)
                    requires sized_sentinel_for<sentinel_t<V>, iterator_t<V>>;
        };
}
```

NOTE *sentinel* is used only when *slide-caches-first*<V> is true.

```
constexpr explicit sentinel(sentinel_t<V> end);
```

Effects: Initializes *end_* with *end*.

```
friend constexpr bool operator==(const iterator<false>& x, const sentinel& y);
```

Returns: *x.last_ele_* == *y.end_*.

```
friend constexpr range_difference_t<V>
    operator-(const iterator<false>& x, const sentinel& y)
        requires sized_sentinel_for<sentinel_t<V>, iterator_t<V>>;
```

Returns: *x.last_ele_* - *y.end_*.

```
friend constexpr range_difference_t<V>
    operator-(const sentinel& y, const iterator<false>& x)
        requires sized_sentinel_for<sentinel_t<V>, iterator_t<V>>;
```

Returns: *y.end_* - *x.last_ele_*.

26.7.30 Chunk by view**[range.chunk.by]****26.7.30.1 Overview****[range.chunk.by.overview]**

`chunk_by_view` takes a view and a predicate, and splits the view into **subranges** between each pair of adjacent elements for which the predicate returns **false**.

The name `views::chunk_by` denotes a range adaptor object (26.7.2). Given subexpressions *E* and *F*, the expression `views::chunk_by(E, F)` is expression-equivalent to `chunk_by_view(E, F)`.

EXAMPLE

```
vector v = {1, 2, 2, 3, 0, 4, 5, 2};

for (auto r : v | views::chunk_by(ranges::less_equal{})) {
    cout << '[';
    auto sep = "";
    for (auto i : r) {
        cout << sep << i;
        sep = ", ";
    }
    cout << "]" << " ";
}
// The above prints [1, 2, 2, 3] [0, 4, 5] [2]
```

26.7.30.2 Class template `chunk_by_view`**[range.chunk.by.view]**

```
namespace std::ranges {
    template<forward_range V, indirect_binary_predicate<iterator_t<V>, iterator_t<V>> Pred>
        requires view<V> && is_object_v<Pred>
    class chunk_by_view : public view_interface<chunk_by_view<V, Pred>> {
        V base_ = V(); // exposition only
        movable_box<Pred> pred_; // exposition only

        // 26.7.30.3, class chunk_by_view::iterator
        class iterator; // exposition only

    public:
        chunk_by_view() requires default_initializable<V> && default_initializable<Pred> = default;
        constexpr explicit chunk_by_view(V base, Pred pred);

        constexpr V base() const & requires copy_constructible<V> { return base_; }
        constexpr V base() && { return std::move(base_); }

        constexpr const Pred& pred() const;

        constexpr iterator begin();
        constexpr auto end();

        constexpr iterator_t<V> find_next(iterator_t<V>); // exposition only
        constexpr iterator_t<V> find_prev(iterator_t<V>) // exposition only
            requires bidirectional_range<V>;
    };

    template<class R, class Pred>
        chunk_by_view(R&&, Pred) -> chunk_by_view<views::all_t<R>, Pred>;
}
```

```
constexpr explicit chunk_by_view(V base, Pred pred);
```

Effects: Initializes `base_` with `std::move(base)` and `pred_` with `std::move(pred)`.

```
constexpr const Pred& pred() const;
```

Effects: Equivalent to: `return *pred_;`

```
constexpr iterator begin();
```

Preconditions: `pred_.has_value()` is true.

Returns: `iterator(*this, ranges::begin(base_), find-next(ranges::begin(base_)))`.

Remarks: In order to provide the amortized constant-time complexity required by the `range` concept, this function caches the result within the `chunk_by_view` for use on subsequent calls.

```
constexpr auto end();
```

Effects: Equivalent to:

```
if constexpr (common_range<V>) {
    return iterator(*this, ranges::end(base_), ranges::end(base_));
} else {
    return default_sentinel;
}
```

```
constexpr iterator_t<V> find-next(iterator_t<V> current);
```

Preconditions: `pred_.has_value()` is true.

Returns:

```
ranges::next(ranges::adjacent_find(current, ranges::end(base_), not_fn(ref(*pred_))),
             1, ranges::end(base_))
```

```
constexpr iterator_t<V> find-prev(iterator_t<V> current) requires bidirectional_range<V>;
```

Preconditions:

- `current` is not equal to `ranges::begin(base_)`.
- `pred_.has_value()` is true.

Returns: An iterator `i` in the range `[ranges::begin(base_), current)` such that:

- `ranges::adjacent_find(i, current, not_fn(ref(*pred_)))` is equal to `current`; and
- if `i` is not equal to `ranges::begin(base_)`, then `bool(involve(*pred_, *ranges::prev(i), *i))` is false.

26.7.30.3 Class `chunk_by_view::iterator`

[range.chunk.by.iter]

```
namespace std::ranges {
    template<forward_range V, indirect_binary_predicate<iterator_t<V>, iterator_t<V>> Pred>
        requires view<V> && is_object_v<Pred>
    class chunk_by_view<V, Pred>::iterator {
        chunk_by_view* parent_ = nullptr;           // exposition only
        iterator_t<V> current_ = iterator_t<V>();   // exposition only
        iterator_t<V> next_ = iterator_t<V>();       // exposition only

        constexpr iterator(chunk_by_view& parent, iterator_t<V> current, // exposition only
                           iterator_t<V> next);

    public:
        using value_type = subrange<iterator_t<V>>;
        using difference_type = range_difference_t<V>;
        using iterator_category = input_iterator_tag;
        using iterator_concept = see below;

        iterator() = default;

        constexpr value_type operator*() const;
        constexpr iterator& operator++();
        constexpr iterator operator++(int);

        constexpr iterator& operator--() requires bidirectional_range<V>;
        constexpr iterator operator--(int) requires bidirectional_range<V>;

        friend constexpr bool operator==(const iterator& x, const iterator& y);
        friend constexpr bool operator==(const iterator& x, default_sentinel_t);
    };
}
```

`iterator::iterator_concept` is defined as follows:

- If `V` models `bidirectional_range`, then `iterator_concept` denotes `bidirectional_iterator_tag`.
- Otherwise, `iterator_concept` denotes `forward_iterator_tag`.

```
constexpr iterator(chunk_by_view& parent, iterator_t<V> current, iterator_t<V> next);
```

Effects: Initializes `parent_` with `addressof(parent)`, `current_` with `current`, and `next_` with `next`.

```
constexpr value_type operator*() const;
```

Preconditions: `current_` is not equal to `next_`.

Returns: `subrange(current_, next_)`.

```
constexpr iterator& operator++();
```

Preconditions: `current_` is not equal to `next_`.

Effects: Equivalent to:

```
current_ = next_;
next_ = parent_->find-next(current_);
return *this;
```

```
constexpr iterator operator++(int);
```

Effects: Equivalent to:

```
auto tmp = *this;
++*this;
return tmp;
```

```
constexpr iterator& operator--() requires bidirectional_range<V>;
```

Effects: Equivalent to:

```
next_ = current_;
current_ = parent_->find-prev(next_);
return *this;
```

```
constexpr iterator operator--(int) requires bidirectional_range<V>;
```

Effects: Equivalent to:

```
auto tmp = *this;
--*this;
return tmp;
```

```
friend constexpr bool operator==(const iterator& x, const iterator& y);
```

Returns: `x.current_ == y.current_`.

```
friend constexpr bool operator==(const iterator& x, default_sentinel_t);
```

Returns: `x.current_ == x.next_`.

26.7.31 Stride view

[range.stride]

26.7.31.1 Overview

[range.stride.overview]

`stride_view` presents a view of an underlying sequence, advancing over n elements at a time, as opposed to the usual single-step succession.

The name `views::stride` denotes a range adaptor object (26.7.2). Given subexpressions `E` and `N`, the expression `views::stride(E, N)` is expression-equivalent to `stride_view(E, N)`.

EXAMPLE

```
auto input = views::iota(0, 12) | views::stride(3);
ranges::copy(input, ostream_iterator<int>(cout, " ")); // prints 0 3 6 9
ranges::copy(input | views::reverse, ostream_iterator<int>(cout, " ")); // prints 9 6 3 0
```

26.7.31.2 Class template `stride_view`

[range.stride.view]

```

namespace std::ranges {
    template<input_range V>
        requires view<V>
    class stride_view : public view_interface<stride_view<V>> {
        V base_; // exposition only
        range_difference_t<V> stride_; // exposition only
        // 26.7.31.3, class template stride_view::iterator
        template<bool> class iterator; // exposition only
    public:
        constexpr explicit stride_view(V base, range_difference_t<V> stride);

        constexpr V base() const & requires copy_constructible<V> { return base_; }
        constexpr V base() && { return std::move(base_); }

        constexpr range_difference_t<V> stride() const noexcept;

        constexpr auto begin() requires (!simple-view<V>) {
            return iterator<false>(this, ranges::begin(base_));
        }

        constexpr auto begin() const requires range<const V> {
            return iterator<true>(this, ranges::begin(base_));
        }

        constexpr auto end() requires (!simple-view<V>) {
            if constexpr (common_range<V> && sized_range<V> && forward_range<V>) {
                auto missing = (stride_ - ranges::distance(base_) % stride_) % stride_;
                return iterator<false>(this, ranges::end(base_), missing);
            } else if constexpr (common_range<V> && !bidirectional_range<V>) {
                return iterator<false>(this, ranges::end(base_));
            } else {
                return default_sentinel;
            }
        }

        constexpr auto end() const requires range<const V> {
            if constexpr (common_range<const V> && sized_range<const V> && forward_range<const V>) {
                auto missing = (stride_ - ranges::distance(base_) % stride_) % stride_;
                return iterator<true>(this, ranges::end(base_), missing);
            } else if constexpr (common_range<const V> && !bidirectional_range<const V>) {
                return iterator<true>(this, ranges::end(base_));
            } else {
                return default_sentinel;
            }
        }

        constexpr auto size() requires sized_range<V>;
        constexpr auto size() const requires sized_range<const V>;
    };

    template<class R>
        stride_view(R&&, range_difference_t<R>) -> stride_view<views::all_t<R>>;
}

```

```
constexpr stride_view(V base, range_difference_t<V> stride);
```

Preconditions: `stride > 0` is true.

Effects: Initializes `base_` with `std::move(base)` and `stride_` with `stride`.

```
constexpr range_difference_t<V> stride() const noexcept;
```

Returns: `stride_`.

```
constexpr auto size() requires sized_range<V>;
constexpr auto size() const requires sized_range<const V>;
```

Effects: Equivalent to:

```
return to-unsigned-like(div-ceil(ranges::distance(base_), stride_));
```

26.7.31.3 Class template `stride_view::iterator`

[range.stride.iterator]

```
namespace std::ranges {
    template<input_range V>
        requires view<V>
    template<bool Const>
    class stride_view<V>::iterator {
        using Parent = maybe-const<Const, stride_view>;
        using Base = maybe-const<Const, V>;

    requires indirectly_swappable<iterator_t<Base>>;
};
}

```

iterator::iterator_concept is defined as follows:

- If *Base* models *random_access_range*, then *iterator_concept* denotes *random_access_iterator_tag*.
- Otherwise, if *Base* models *bidirectional_range*, then *iterator_concept* denotes *bidirectional_iterator_tag*.
- Otherwise, if *Base* models *forward_range*, then *iterator_concept* denotes *forward_iterator_tag*.
- Otherwise, *iterator_concept* denotes *input_iterator_tag*.

The member *typedef-name iterator_category* is defined if and only if *Base* models *forward_range*. In that case, *iterator::iterator_category* is defined as follows:

- Let *C* denote the type *iterator_traits<iterator_t<Base>>::iterator_category*.
- If *C* models *derived_from<random_access_iterator_tag>*, then *iterator_category* denotes *random_access_iterator_tag*.
- Otherwise, *iterator_category* denotes *C*.

```

constexpr iterator (Parent* parent, iterator_t<Base> current,
    range_difference_t<Base> missing = 0);

```

Effects: Initializes *current_* with `std::move(current)`, *end_* with `ranges::end(parent->base_)`, *stride_* with `parent->stride_`, and *missing_* with *missing*.

```

constexpr iterator (iterator<!Const> i)
    requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>
    && convertible_to<sentinel_t<V>, sentinel_t<Base>>;

```

Effects: Initializes *current_* with `std::move(i.current_)`, *end_* with `std::move(i.end_)`, *stride_* with *i.stride_*, and *missing_* with *i.missing_*.

```

constexpr iterator_t<Base> base() &&;

```

Returns: `std::move(current_)`.

```
constexpr const iterator_t<Base>& base() const & noexcept;
```

Returns: *current_*.

```
constexpr iterator& operator++();
```

Preconditions: *current_ != end_* is true.

Effects: Equivalent to:

```
missing_ = ranges::advance(current_, stride_, end_);
return *this;
```

```
constexpr void operator++(int);
```

Effects: Equivalent to: *++*this*;

```
constexpr iterator operator++(int) requires forward_range<Base>;
```

Effects: Equivalent to:

```

    requires indirectly_swappable<iterator_t<Base>>;
```

Effects: Equivalent to: `ranges::iter_swap(x.current_, y.current_);`

26.7.32 Cartesian product view**[range.cartesian]****26.7.32.1 Overview****[range.cartesian.overview]**

`cartesian_product_view` takes any non-zero number of ranges n and produces a view of tuples calculated by the n -ary cartesian product of the provided ranges.

The name `views::cartesian_product` denotes a customization point object (16.3.3.3.5). Given a pack of subexpressions `Es`, the expression `views::cartesian_product(Es...)` is expression-equivalent to

- `views::single(tuple())` if `Es` is an empty pack,
- otherwise, `cartesian_product_view<views::all_t<decltype((Es))>>...>(Es...)`.

EXAMPLE

```
vector<int> v { 0, 1, 2 };
for (auto&& [a, b, c] : views::cartesian_product(v, v, v)) {
    cout << a << ' ' << b << ' ' << c << '\n';
}
// The above prints
// 0 0 0
// 0 0 1
// 0 0 2
// 0 1 0
// 0 1 1
// ...
```

26.7.32.2 Class template `cartesian_product_view`**[range.cartesian.view]**

```
namespace std::ranges {
    template<bool Const, class First, class... Vs>
    concept cartesian_product_is_random_access = // exposition only
        (random_access_range<maybe_const<Const, First>> && ... &&
         (random_access_range<maybe_const<Const, Vs>>
          && sized_range<maybe_const<Const, Vs>>));

    template<class R>
    concept cartesian_product_common_arg = // exposition only
        common_range<R> || (sized_range<R> && random_access_range<R>);

    template<bool Const, class First, class... Vs>
    concept cartesian_product_is_bidirectional = // exposition only
        (bidirectional_range<maybe_const<Const, First>> && ... &&
         (bidirectional_range<maybe_const<Const, Vs>>
          && cartesian_product_common_arg<maybe_const<Const, Vs>>));

    template<class First, class... Vs>
    concept cartesian_product_is_common = // exposition only
        cartesian_product_common_arg<First>;

    template<class... Vs>
    concept cartesian_product_is_sized = // exposition only
        (sized_range<Vs> && ...);

    template<bool Const, template<class> class FirstSent, class First, class... Vs>
    concept cartesian_is_sized_sentinel = // exposition only
        (sized_sentinel_for<FirstSent<maybe_const<Const, First>>,
         iterator_t<maybe_const<Const, First>>> && ...
         && (sized_range<maybe_const<Const, Vs>>
          && sized_sentinel_for<iterator_t<maybe_const<Const, Vs>>,
           iterator_t<maybe_const<Const, Vs>>>));

    template<cartesian_product_common_arg R>
    constexpr auto cartesian_common_arg_end(R& r) { // exposition only
        if constexpr (common_range<R>) {
            return ranges::end(r);
        } else {
```

```

    return ranges::begin(r) + ranges::distance(r);
}
}

template<input_range First, forward_range... Vs>
    requires (view<First> && ... && view<Vs>)
class cartesian_product_view : public view_interface<cartesian_product_view<First, Vs...>> {
private:
    tuple<First, Vs...> bases_; // exposition only
    // 26.7.32.3, class template cartesian_product_view::iterator
    template<bool Const> class iterator; // exposition only

public:
    constexpr cartesian_product_view() = default;
    constexpr explicit cartesian_product_view(First first_base, Vs... bases);

    constexpr iterator<false> begin()
        requires (!simple-view<First> || ... || !simple-view<Vs>);
    constexpr iterator<true> begin() const
        requires (range<const First> && ... && range<const Vs>);

    constexpr iterator<false> end()
        requires ((!simple-view<First> || ... || !simple-view<Vs>) &&
            cartesian-product-is-common<First, Vs...>);
    constexpr iterator<true> end() const
        requires cartesian-product-is-common<const First, const Vs...>;
    constexpr default_sentinel_t end() const noexcept;

    constexpr see below size()
        requires cartesian-product-is-sized<First, Vs...>;
    constexpr see below size() const
        requires cartesian-product-is-sized<const First, const Vs...>;
};

template<class... Vs>
    cartesian_product_view(Vs&&...) -> cartesian_product_view<views::all_t<Vs>...>;
}

constexpr explicit cartesian_product_view(First first_base, Vs... bases);

Effects: Initializes bases_ with std::move(first_base), std::move(bases)....

constexpr iterator<false> begin()
    requires (!simple-view<First> || ... || !simple-view<Vs>);

Effects: Equivalent to:

    return iterator<false>(*this, tuple-transform(ranges::begin, bases_));

constexpr iterator<true> begin() const
    requires (range<const First> && ... && range<const Vs>);

Effects: Equivalent to:

    return iterator<true>(*this, tuple-transform(ranges::begin, bases_));

constexpr iterator<false> end()
    requires ((!simple-view<First> || ... || !simple-view<Vs>)
        && cartesian-product-is-common<First, Vs...>);
constexpr iterator<true> end() const
    requires cartesian-product-is-common<const First, const Vs...>;

Let:
    — is-const be true for the const-qualified overload, and false otherwise;
    — is-empty be true if the expression ranges::empty(rng) is true for any rng among the underlying
        ranges except the first one and false otherwise; and

```

- *begin-or-first-end*(rng) be expression-equivalent to *is-empty* ? *ranges::begin*(rng) : *cartesian-common-arg-end*(rng) if rng is the first underlying range and *ranges::begin*(rng) otherwise.

Effects: Equivalent to:

```
iterator<is-const> it(*this, tuple-transform(
    [](auto& rng){ return begin-or-first-end(rng); }, bases_));
return it;
```

```
constexpr default_sentinel_t end() const noexcept;
```

Returns: default_sentinel.

```
constexpr see below size()
    requires cartesian-product-is-sized<First, Vs...>;
constexpr see below size() const
    requires cartesian-product-is-sized<const First, const Vs...>;
```

The return type is an implementation-defined unsigned-integer-like type.

Recommended practice: The return type should be the smallest unsigned-integer-like type that is sufficiently wide to store the product of the maximum sizes of all the underlying ranges, if such a type exists.

Let *p* be the product of the sizes of all the ranges in *bases_*.

Preconditions: *p* can be represented by the return type.

Returns: *p*.

26.7.32.3 Class template `cartesian_product_view::iterator` [range.cartesian.iterator]

```

constexpr iterator operator++(int) requires forward_range<maybe-const<Const, First>>;
```

Effects: Equivalent to:

```
auto tmp = *this;
++*this;
return tmp;
```

```
constexpr iterator& operator--()
```

```
requires cartesian-product-is-bidirectional<Const, First, Vs...>;
```

Effects: Equivalent to:

```
prev();
return *this;
```

```
constexpr iterator operator--(int)
```

```
requires cartesian-product-is-bidirectional<Const, First, Vs...>;
```

Effects: Equivalent to:

```
auto tmp = *this;
--*this;
return tmp;
```

```
constexpr iterator& operator+=(difference_type x)
```

```
requires cartesian-product-is-random-access<Const, First, Vs...>;
```

Let `orig` be the value of `*this` before the call.

Let `ret` be:

- If $x > 0$, the value of `*this` had *next* been called x times.
- Otherwise, if $x < 0$, the value of `*this` had *prev* been called $-x$ times.
- Otherwise, `orig`.

Preconditions: x is in the range `[ranges::distance(*this, ranges::begin(*parent_)), ranges::distance(*this, ranges::end(*parent_))]`.

Effects: Sets the value of `*this` to `ret`.

Returns: `*this`.

Complexity: Constant.

```
constexpr iterator& operator-=(difference_type x)
```

```
requires cartesian-product-is-random-access<Const, First, Vs...>;
```

Effects: Equivalent to:

```
*this += -x;
return *this;
```

```
constexpr reference operator[](difference_type n) const
```

```
requires cartesian-product-is-random-access<Const, First, Vs...>;
```

Effects: Equivalent to: `return *((*this) + n);`

```
friend constexpr bool operator==(const iterator& x, const iterator& y)
```

```
requires equality_comparable<iterator_t<maybe-const<Const, First>>>;
```

Effects: Equivalent to: `return x.current_ == y.current_;`

```
friend constexpr bool operator==(const iterator& x, default_sentinel_t);
```

Returns: `true` if `std::get<i>(x.current_) == ranges::end(std::get<i>(x.parent_>bases_))` is true for any integer $0 \leq i \leq \text{sizeof} \dots (\text{Vs})$; otherwise, `false`.

```
friend constexpr auto operator<=>(const iterator& x, const iterator& y)
    requires all-random-access<Const, First, Vs...>;
```

Effects: Equivalent to: `return x.current_ <= y.current_;`

```
friend constexpr iterator operator+(const iterator& x, difference_type y)
    requires cartesian-product-is-random-access<Const, First, Vs...>;
```

Effects: Equivalent to: `return iterator(x) += y;`

```
friend constexpr iterator operator+(difference_type x, const iterator& y)
    requires cartesian-product-is-random-access<Const, First, Vs...>;
```

Effects: Equivalent to: `return y + x;`

```
friend constexpr iterator operator-(const iterator& x, difference_type y)
    requires cartesian-product-is-random-access<Const, First, Vs...>;
```

Effects: Equivalent to: `return iterator(x) -= y;`

```
friend constexpr difference_type operator-(const iterator& x, const iterator& y)
    requires cartesian-is-sized-sentinel<Const, iterator_t, First, Vs...>;
```

Effects: Equivalent to: `return x.distance-from(y.current_);`

```
friend constexpr difference_type operator-(const iterator& i, default_sentinel_t)
    requires cartesian-is-sized-sentinel<Const, sentinel_t, First, Vs...>;
```

Let *end-tuple* be an object of a type that is a specialization of *tuple*, such that:

- `std::get<0>(end-tuple)` has the same value as `ranges::end(std::get<0>(i.parent_->bases_))`;
- `std::get<N>(end-tuple)` has the same value as `ranges::begin(std::get<N>(i.parent_->bases_))` for every integer $1 \leq N \leq \text{sizeof} \dots (\text{Vs})$.

Effects: Equivalent to: `return i.distance-from(end-tuple);`

```
friend constexpr difference_type operator-(default_sentinel_t s, const iterator& i)
    requires cartesian-is-sized-sentinel<Const, sentinel_t, First, Vs...>;
```

Effects: Equivalent to: `return -(i - s);`

```
friend constexpr auto iter_move(const iterator& i) noexcept(see below);
```

Effects: Equivalent to: `return tuple-transform(ranges::iter_move, i.current_);`

Remarks: The exception specification is equivalent to the logical AND of the following expressions:

- `noexcept(ranges::iter_move(std::get<N>(i.current_)))` for every integer $0 \leq N \leq \text{sizeof} \dots (\text{Vs})$,
- `is_nothrow_move_constructible_v<range_rvalue_reference_t<maybe-const<Const, T>>>` for every type *T* in *First, Vs...*

```
friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept(see below)
    requires (indirectly_swappable<iterator_t<maybe-const<Const, First>>> && ... &&
        indirectly_swappable<iterator_t<maybe-const<Const, Vs>>>);
```

Effects: For every integer $0 \leq i \leq \text{sizeof} \dots (\text{Vs})$, performs:

`ranges::iter_swap(std::get<i>(l.current_), std::get<i>(r.current_))`

Remarks: The exception specification is equivalent to the logical AND of the following expressions:

- `noexcept(ranges::iter_swap(std::get<i>(l.current_), std::get<i>(r.current_)))` for every integer $0 \leq i \leq \text{sizeof} \dots (\text{Vs})$.

26.8 Range generators

[coro.generator]

26.8.1 Overview

[coroutine.generator.overview]

Class template **generator** presents a view of the elements yielded by the evaluation of a coroutine.

A **generator** generates a sequence of elements by repeatedly resuming the coroutine from which it was returned. Elements of the sequence are produced by the coroutine each time a `co_yield` statement is

evaluated. When the `co_yield` statement is of the form `co_yield elements_of(r)`, each element of the range `r` is successively produced as an element of the sequence.

EXAMPLE

```
generator<int> ints(int start = 0) {
    while (true)
        co_yield start++;
}

void f() {
    for (auto i : ints() | views::take(3))
        cout << i << ' ';    // prints 0 1 2
}
```

26.8.2 Header <generator> synopsis

[generator.syn]

```
namespace std {
    // 26.8.3, class template generator
    template<class Ref, class V = void, class Allocator = void>
        class generator;

    namespace pmr {
        template<class R, class V = void>
            using generator = std::generator<R, V, polymorphic_allocator<>>;
    }
}
```

26.8.3 Class template generator

[coro.generator.class]

```
namespace std {
    template<class Ref, class V = void, class Allocator = void>
    class generator : public ranges::view_interface<generator<Ref, V, Allocator>> {
    private:
        using value = conditional_t<is_void_v<V>, remove_cvref_t<Ref>, V>;    // exposition only
        using reference = conditional_t<is_void_v<V>, Ref&&, Ref>;    // exposition only

        // 26.8.6, class generator::iterator
        class iterator;    // exposition only

    public:
        using yielded =
            conditional_t<is_reference_v<reference>, reference, const reference&>;

        // 26.8.5, class generator::promise_type
        class promise_type;

        generator(const generator&) = delete;
        generator(generator&& other) noexcept;

        ~generator();

        generator& operator=(generator other) noexcept;

        iterator begin();
        default_sentinel_t end() const noexcept;

    private:
        coroutine_handle<promise_type> coroutine_ = nullptr;    // exposition only
        unique_ptr<stack<coroutine_handle<>>> active_;    // exposition only
    };
}
```

Mandates:

- If `Allocator` is not `void`, `allocator_traits<Allocator>::pointer` is a pointer type.
- `value` is a cv-unqualified object type.

- *reference* is either a reference type, or a cv-unqualified object type that models `copy_constructible`.
- Let `RRef` denote `remove_reference_t<reference>&&` if *reference* is a reference type, and *reference* otherwise. Each of:
 - `common_reference_with<reference&&, value&>`,
 - `common_reference_with<reference&&, RRef&&>`, and
 - `common_reference_with<RRef&&, const value&>`

is modeled.

NOTE These requirements ensure the exposition-only *iterator* type can model *indirectly_readable* and thus *input_iterator*.

If `Allocator` is not `void`, it shall meet the *Cpp17Allocator* requirements.

Specializations of `generator` model view and `input_range`.

The behavior of a program that adds a specialization for `generator` is undefined.

26.8.4 Members

[`coro.generator.members`]

`generator(generator&& other) noexcept;`

Effects: Initializes `coroutine_` with `exchange(other.coroutine_, {})` and `active_` with `exchange(other.active_, nullptr)`.

NOTE 1 Iterators previously obtained from `other` are not invalidated; they become iterators into `*this`.

`~generator();`

Effects: Equivalent to:

```
if (coroutine_) {
    coroutine_.destroy();
}
```

NOTE 2 Ownership of recursively yielded generators is held in awaitable objects in the coroutine frame of the yielding generator, so destroying the root generator effectively destroys the entire stack of yielded generators.

`generator& operator=(generator other) noexcept;`

Effects: Equivalent to:

```
swap(coroutine_, other.coroutine_);
swap(active_, other.active_);
```

Returns: `*this`.

NOTE 3 Iterators previously obtained from `other` are not invalidated; they become iterators into `*this`.

`iterator begin();`

Preconditions: `coroutine_` refers to a coroutine suspended at its initial suspend point (9.5.4).

Effects: Pushes `coroutine_` into `*active_`, then evaluates `coroutine_.resume()`.

Returns: An *iterator* object whose member `coroutine_` refers to the same coroutine as does `coroutine_`.

NOTE 4 A program that calls `begin` more than once on the same generator has undefined behavior.

`default_sentinel_t end() const noexcept;`

Returns: `default_sentinel`.

26.8.5 Class `generator::promise_type`

[`coro.generator.promise`]

```
namespace std {
    template<class Ref, class V, class Allocator>
    class generator<Ref, V, Allocator>::promise_type {
    public:
        generator get_return_object() noexcept;

        suspend_always initial_suspend() const noexcept { return {}; }
        auto final_suspend() noexcept;
```

```

suspend_always yield_value(yielded val) noexcept;

auto yield_value(const remove_reference_t<yielded>& lval)
    requires is_rvalue_reference_v<yielded> &&
    constructible_from<remove_cvref_t<yielded>, const remove_reference_t<yielded>&>;

template<class R2, class V2, class Alloc2, class Unused>
    requires same_as<typename generator<R2, V2, Alloc2>::yielded, yielded>
    auto yield_value(ranges::elements_of<generator<R2, V2, Alloc2>&&, Unused> g) noexcept;

template<ranges::input_range R, class Alloc>
    requires convertible_to<ranges::range_reference_t<R>, yielded>
    auto yield_value(ranges::elements_of<R, Alloc> r) noexcept;

void await_transform() = delete;

void return_void() const noexcept {}
void unhandled_exception();

void* operator new(size_t size)
    requires same_as<Allocator, void> || default_initializable<Allocator>;

template<class Alloc, class... Args>
    requires same_as<Allocator, void> || convertible_to<const Alloc&, Allocator>
    void* operator new(size_t size, allocator_arg_t, const Alloc& alloc, const Args&...);

template<class This, class Alloc, class... Args>
    requires same_as<Allocator, void> || convertible_to<const Alloc&, Allocator>
    void* operator new(size_t size, const This&, allocator_arg_t, const Alloc& alloc,
        const Args&...);

void operator delete(void* pointer, size_t size) noexcept;

private:
    add_pointer_t<yielded> value_ = nullptr; // exposition only
    exception_ptr except_; // exposition only
};
}

generator get_return_object() noexcept;

Returns: A generator object whose member coroutine_ is coroutine_handle<promise_type>::from_promise(*this), and whose member active_ points to an empty stack.

auto final_suspend() noexcept;

Preconditions: A handle referring to the coroutine whose promise object is *this is at the top of *active_ of some generator object x. This function is called by that coroutine upon reaching its final suspend point (9.5.4).

Returns: An awaitable object of unspecified type (7.6.2.4) whose member functions arrange for the calling coroutine to be suspended, pop the coroutine handle from the top of *x.active_, and resume execution of the coroutine referred to by x.active_→top() if *x.active_ is not empty. If it is empty, control flow returns to the current coroutine caller or resumer (9.5.4).

suspend_always yield_value(yielded val) noexcept;

Effects: Equivalent to value_ = addressof(val).

Returns: {}.

auto yield_value(const remove_reference_t<yielded>& lval)
    requires is_rvalue_reference_v<yielded> &&
    constructible_from<remove_cvref_t<yielded>, const remove_reference_t<yielded>&>;

Preconditions: A handle referring to the coroutine whose promise object is *this is at the top of *active_ of some generator object.

```

Returns: An awaitable object of an unspecified type (7.6.2.4) that stores an object of type `remove_cvref_t<yielded>` direct-non-list-initialized with `lval`, whose member functions arrange for `value_` to point to that stored object and then suspend the coroutine.

Throws: Any exception thrown by the initialization of the stored object.

Remarks: A *yield-expression* that calls this function has type `void` (7.6.17).

```
template<class R2, class V2, class Alloc2, class Unused>
requires same_as<typename generator<R2, V2, Alloc2>::yielded, yielded>
auto yield_value(ranges::elements_of<generator<R2, V2, Alloc2>&&, Unused> g) noexcept;
```

Preconditions: A handle referring to the coroutine whose promise object is `*this` is at the top of `*active_` of some `generator` object `x`. The coroutine referred to by `g.range.coroutine_` is suspended at its initial suspend point.

Returns: An awaitable object of an unspecified type (7.6.2.4) into which `g.range` is moved, whose member `await_ready` returns `false`, whose member `await_suspend` pushes `g.range.coroutine_` into `*x.active_` and resumes execution of the coroutine referred to by `g.range.coroutine_`, and whose member `await_resume` evaluates `rethrow_exception(exception_)` if `bool(exception_)` is true. If `bool(exception_)` is false, the `await_resume` member has no effects.

Remarks: A *yield-expression* that calls this function has type `void` (7.6.17).

```
template<ranges::input_range R, class Alloc>
requires convertible_to<ranges::range_reference_t<R>, yielded>
auto yield_value(ranges::elements_of<R, Alloc> r) noexcept;

Effects: Equivalent to:

    auto nested = [] (allocator_arg_t, Alloc, ranges::iterator_t<R> i, ranges::sentinel_t<R> s)
    -> generator<yielded, ranges::range_value_t<R>, Alloc> {
        for (; i != s; ++i) {
            co_yield static_cast<yielded>(*i);
        }
    };
    return yield_value(ranges::elements_of(nested(
        allocator_arg, r.allocator, ranges::begin(r.range), ranges::end(r.range))));
```

NOTE A *yield-expression* that calls this function has type `void` (7.6.17).

```
void unhandled_exception();
```

Preconditions: A handle referring to the coroutine whose promise object is `*this` is at the top of `*active_` of some `generator` object `x`.

Effects: If the handle referring to the coroutine whose promise object is `*this` is the sole element of `*x.active_`, equivalent to `throw`, otherwise, assigns `current_exception()` to `exception_`.

```
void* operator new(size_t size)
requires same_as<Allocator, void> || default_initializable<Allocator>;

template<class Alloc, class... Args>
requires same_as<Allocator, void> || convertible_to<const Alloc&, Allocator>
void* operator new(size_t size, allocator_arg_t, const Alloc& alloc, const Args&...);

template<class This, class Alloc, class... Args>
requires same_as<Allocator, void> || convertible_to<const Alloc&, Allocator>
void* operator new(size_t size, const This&, allocator_arg_t, const Alloc& alloc,
    const Args&...);
```

Let A be

- `Allocator`, if it is not `void`,
- `Alloc` for the overloads with a template parameter `Alloc`, or
- `allocator<void>` otherwise.

Let B be `allocator_traits<A>::template rebind_alloc<U>` where U is an unspecified type whose size and alignment are both `__STDCPP_DEFAULT_NEW_ALIGNMENT__`.

Mandates: `allocator_traits<B>::pointer` is a pointer type.

Effects: Initializes an allocator `b` of type `B` with `A(alloc)`, for the overloads with a function parameter `alloc`, and with `A()` otherwise. Uses `b` to allocate storage for the smallest array of `U` sufficient to provide storage for a coroutine state of size `size`, and unspecified additional state necessary to ensure that `operator delete` can later deallocate this memory block with an allocator equal to `b`.

Returns: A pointer to the allocated storage.

```
void operator delete(void* pointer, size_t size) noexcept;
```

Preconditions: `pointer` was returned from an invocation of one of the above overloads of `operator new` with a `size` argument equal to `size`.

Effects: Deallocates the storage pointed to by `pointer` using an allocator equivalent to that used to allocate it.

26.8.6 Class `generator::iterator`

[`coro.generator.iterator`]

```
namespace std {
    template<class Ref, class V, class Allocator>
    class generator<Ref, V, Allocator>::iterator {
    public:
        using value_type = value;
        using difference_type = ptrdiff_t;

        iterator(iterator&& other) noexcept;
        iterator& operator=(iterator&& other) noexcept;

        reference operator*() const noexcept(is_nothrow_copy_constructible_v<reference>);
        iterator& operator++();
        void operator++(int);

        friend bool operator==(const iterator& i, default_sentinel_t);

    private:
        coroutine_handle<promise_type> coroutine_; // exposition only
    };
}
```

```
iterator(iterator&& other) noexcept;
```

Effects: Initializes `coroutine_` with `exchange(other.coroutine_, {})`.

```
iterator& operator=(iterator&& other) noexcept;
```

Effects: Equivalent to `coroutine_ = exchange(other.coroutine_, {})`.

Returns: `*this`.

```
reference operator*() const noexcept(is_nothrow_copy_constructible_v<reference>);
```

Preconditions: For some generator object `x`, `coroutine_` is in `*x.active_` and `x.active_>top()` refers to a suspended coroutine with promise object `p`.

Effects: Equivalent to: `return static_cast<reference>(*p.value_);`

```
iterator& operator++();
```

Preconditions: For some generator object `x`, `coroutine_` is in `*x.active_`.

Effects: Equivalent to `x.active_>top().resume()`.

Returns: `*this`.

```
void operator++(int);
```

Effects: Equivalent to `++*this`.

```
friend bool operator==(const iterator& i, default_sentinel_t);
```

Effects: Equivalent to: `return i.coroutine_.done();`

27 Algorithms library

[algorithms]

27.1 General

[algorithms.general]

This Clause describes components that C++ programs may use to perform algorithmic operations on containers (Clause 24) and other sequences.

The following subclauses describe components for non-modifying sequence operations, mutating sequence operations, sorting and related operations, and algorithms from the C library, as summarized in Table 93.

Table 93 — Algorithms library summary [tab:algorithms.summary]

Subclause	Header
27.2 Algorithms requirements	
27.3 Parallel algorithms	
27.5 Algorithm result types	<algorithm>
27.6 Non-modifying sequence operations	
27.7 Mutating sequence operations	
27.8 Sorting and related operations	
27.10 Generalized numeric operations	<numeric>
27.11 Specialized <memory> algorithms	<memory>
27.12 C library algorithms	<cstdlib>

27.2 Algorithms requirements

[algorithms.requirements]

All of the algorithms are separated from the particular implementations of data structures and are parameterized by iterator types. Because of this, they can work with program-defined data structures, as long as these data structures have iterator types satisfying the assumptions on the algorithms.

The entities defined in the `std::ranges` namespace in this Clause are not found by argument-dependent name lookup (6.5.4). When found by unqualified (6.5.3) name lookup for the *postfix-expression* in a function call (7.6.1.3), they inhibit argument-dependent name lookup.

EXAMPLE

```
void foo() {
    using namespace std::ranges;
    std::vector<int> vec{1,2,3};
    find(begin(vec), end(vec), 2);    // #1
}
```

The function call expression at #1 invokes `std::ranges::find`, not `std::find`, despite that (a) the iterator type returned from `begin(vec)` and `end(vec)` may be associated with namespace `std` and (b) `std::find` is more specialized (13.7.7.3) than `std::ranges::find` since the former requires its first two parameters to have the same type.

For purposes of determining the existence of data races, algorithms shall not modify objects referenced through an iterator argument unless the specification requires such modification.

Throughout this Clause, where the template parameters are not constrained, the names of template parameters are used to express type requirements.

- If an algorithm's *Effects* element specifies that a value pointed to by any iterator passed as an argument is modified, then the type of that argument shall meet the requirements of a mutable iterator (25.3).
- If an algorithm's template parameter is named `InputIterator`, `InputIterator1`, or `InputIterator2`, the template argument shall meet the *Cpp17InputIterator* requirements (25.3.5.3).
- If an algorithm's template parameter is named `OutputIterator`, `OutputIterator1`, or `OutputIterator2`, the template argument shall meet the *Cpp17OutputIterator* requirements (25.3.5.4).
- If an algorithm's template parameter is named `ForwardIterator`, `ForwardIterator1`, `ForwardIterator2`, or `NoThrowForwardIterator`, the template argument shall meet the *Cpp17ForwardIterator*

requirements (25.3.5.5) if it is required to be a mutable iterator, or model `forward_iterator` (25.3.4.11) otherwise.

- If an algorithm's template parameter is named `NoThrowForwardIterator`, the template argument is also required to have the property that no exceptions are thrown from increment, assignment, or comparison of, or indirection through, valid iterators.
- If an algorithm's template parameter is named `BidirectionalIterator`, `BidirectionalIterator1`, or `BidirectionalIterator2`, the template argument shall meet the *Cpp17BidirectionalIterator* requirements (25.3.5.6) if it is required to be a mutable iterator, or model `bidirectional_iterator` (25.3.4.12) otherwise.
- If an algorithm's template parameter is named `RandomAccessIterator`, `RandomAccessIterator1`, or `RandomAccessIterator2`, the template argument shall meet the *Cpp17RandomAccessIterator* requirements (25.3.5.7) if it is required to be a mutable iterator, or model `random_access_iterator` (25.3.4.13) otherwise.

NOTE 1 These requirements do not affect iterator arguments that are constrained, for which iterator category and mutability requirements are expressed explicitly.

Both in-place and copying versions are provided for certain algorithms.²¹⁴ When such a version is provided for *algorithm* it is called *algorithm_copy*. Algorithms that take predicates end with the suffix `_if` (which follows the suffix `_copy`).

When not otherwise constrained, the `Predicate` parameter is used whenever an algorithm expects a function object (22.10) that, when applied to the result of dereferencing the corresponding iterator, returns a value testable as `true`. If an algorithm takes `Predicate pred` as its argument and `first` as its iterator argument with value type `T`, the expression `pred(*first)` shall be well-formed and the type `decltype(pred(*first))` shall model *boolean-testable* (18.5.2). The function object `pred` shall not apply any non-constant function through its argument. Given a glvalue `u` of type (possibly `const`) `T` that designates the same object as `*first`, `pred(u)` shall be a valid expression that is equal to `pred(*first)`.

When not otherwise constrained, the `BinaryPredicate` parameter is used whenever an algorithm expects a function object that, when applied to the result of dereferencing two corresponding iterators or to dereferencing an iterator and type `T` when `T` is part of the signature, returns a value testable as `true`. If an algorithm takes `BinaryPredicate binary_pred` as its argument and `first1` and `first2` as its iterator arguments with respective value types `T1` and `T2`, the expression `binary_pred(*first1, *first2)` shall be well-formed and the type `decltype(binary_pred(*first1, *first2))` shall model *boolean-testable*. Unless otherwise specified, `BinaryPredicate` always takes the first iterator's `value_type` as its first argument, that is, in those cases when `T` value is part of the signature, the expression `binary_pred(*first1, value)` shall be well-formed and the type `decltype(binary_pred(*first1, value))` shall model *boolean-testable*. `binary_pred` shall not apply any non-constant function through any of its arguments. Given a glvalue `u` of type (possibly `const`) `T1` that designates the same object as `*first1`, and a glvalue `v` of type (possibly `const`) `T2` that designates the same object as `*first2`, `binary_pred(u, *first2)`, `binary_pred(*first1, v)`, and `binary_pred(u, v)` shall each be a valid expression that is equal to `binary_pred(*first1, *first2)`, and `binary_pred(u, value)` shall be a valid expression that is equal to `binary_pred(*first1, value)`.

The parameters `UnaryOperation`, `BinaryOperation`, `BinaryOperation1`, and `BinaryOperation2` are used whenever an algorithm expects a function object (22.10).

NOTE 2 Unless otherwise specified, algorithms that take function objects as arguments can copy those function objects freely. If object identity is important, a wrapper class that points to a non-copied implementation object such as `reference_wrapper<T>` (22.10.6), or some equivalent solution, can be used.

When the description of an algorithm gives an expression such as `*first == value` for a condition, the expression shall evaluate to either `true` or `false` in boolean contexts.

In the description of the algorithms, operator `+` is used for some of the iterator categories for which it does not have to be defined. In these cases the semantics of `a + n` are the same as those of

```
auto tmp = a;
for (; n < 0; ++n) --tmp;
for (; n > 0; --n) ++tmp;
return tmp;
```

214) The decision whether to include a copying version was usually based on complexity considerations. When the cost of doing the operation dominates the cost of copy, the copying version is not included. For example, `sort_copy` is not included because the cost of sorting is much more significant, and users can invoke `copy` followed by `sort`.

Similarly, operator `-` is used for some combinations of iterators and sentinel types for which it does not have to be defined. If `[a, b)` denotes a range, the semantics of `b - a` in these cases are the same as those of

```
iter_difference_t<decltype(a)> n = 0;
for (auto tmp = a; tmp != b; ++tmp) ++n;
return n;
```

and if `[b, a)` denotes a range, the same as those of

```
iter_difference_t<decltype(b)> n = 0;
for (auto tmp = b; tmp != a; ++tmp) --n;
return n;
```

In the description of the algorithms, given an iterator `a` whose difference type is `D`, and an expression `n` of integer-like type other than *cv* `D`, the semantics of `a + n` and `a - n` are, respectively, those of `a + D(n)` and `a - D(n)`.

In the description of algorithm return values, a sentinel value `s` denoting the end of a range `[i, s)` is sometimes returned where an iterator is expected. In these cases, the semantics are as if the sentinel is converted into an iterator using `ranges::next(i, s)`.

Overloads of algorithms that take `range` arguments (26.4.2) behave as if they are implemented by calling `ranges::begin` and `ranges::end` on the `range(s)` and dispatching to the overload in namespace `ranges` that takes separate iterator and sentinel arguments.

The well-formedness and behavior of a call to an algorithm with an explicitly-specified template argument list is unspecified, except where explicitly stated otherwise.

NOTE 3 Consequently, an implementation can declare an algorithm with different template parameters than those presented.

27.3 Parallel algorithms

[algorithms.parallel]

27.3.1 Preamble

[algorithms.parallel.defns]

Subclause 27.3 describes components that C++ programs may use to perform operations on containers and other sequences in parallel.

A *parallel algorithm* is a function template listed in this document with a template parameter named `ExecutionPolicy`.

Parallel algorithms access objects indirectly accessible via their arguments by invoking the following functions:

- All operations of the categories of the iterators that the algorithm is instantiated with.
- Operations on those sequence elements that are required by its specification.
- User-provided function objects to be applied during the execution of the algorithm, if required by the specification.
- Operations on those function objects required by the specification.

NOTE 1 See 27.2.

These functions are herein called *element access functions*.

EXAMPLE 1 The `sort` function may invoke the following element access functions:

- Operations of the random-access iterator of the actual template argument (as per 25.3.5.7), as implied by the name of the template parameter `RandomAccessIterator`.
- The `swap` function on the elements of the sequence (as per the preconditions specified in 27.8.2.1).
- The user-provided `Compare` function object.

A standard library function is *vectorization-unsafe* if it is specified to synchronize with another function invocation, or another function invocation is specified to synchronize with it, and if it is not a memory allocation or deallocation function.

NOTE 2 Implementations are expected to ensure that internal synchronization inside standard library functions does not prevent forward progress when those functions are executed by threads of execution with weakly parallel forward progress guarantees.

EXAMPLE 2

```
int x = 0;
std::mutex m;
```

```

void f() {
    int a[] = {1,2};
    std::for_each(std::execution::par_unseq, std::begin(a), std::end(a), [&](int) {
        std::lock_guard<mutex> guard(m);           // incorrect: lock_guard constructor calls m.lock()
        ++x;
    });
}

```

The above program may result in two consecutive calls to `m.lock()` on the same thread of execution (which may deadlock), because the applications of the function object are not guaranteed to run on different threads of execution.

27.3.2 Requirements on user-provided function objects [algorithms.parallel.user]

Unless otherwise specified, function objects passed into parallel algorithms as objects of type `Predicate`, `BinaryPredicate`, `Compare`, `UnaryOperation`, `BinaryOperation`, `BinaryOperation1`, `BinaryOperation2`, and the operators used by the analogous overloads to these parallel algorithms that are formed by an invocation with the specified default predicate or operation (where applicable) shall not directly or indirectly modify objects via their arguments, nor shall they rely on the identity of the provided objects.

27.3.3 Effect of execution policies on algorithm execution [algorithms.parallel.exec]

Parallel algorithms have template parameters named `ExecutionPolicy` (22.12) which describe the manner in which the execution of these algorithms may be parallelized and the manner in which they apply the element access functions.

If an object is modified by an element access function, the algorithm will perform no other unsynchronized accesses to that object. The modifying element access functions are those which are specified as modifying the object.

NOTE 1 For example, `swap`, `++`, `--`, `@=`, and assignments modify the object. For the assignment and `@=` operators, only the left argument is modified.

Unless otherwise stated, implementations may make arbitrary copies of elements (with type `T`) from sequences where `is_trivially_copy_constructible_v<T>` and `is_trivially_destructible_v<T>` are `true`.

NOTE 2 This implies that there is no reliable object identity of arguments in user-supplied function objects for such input sequences. If object identity of the arguments to these function objects is important, a wrapping iterator that returns a non-copied implementation object such as `reference_wrapper<T>` (22.10.6), or some equivalent solution, can be used.

The invocations of element access functions in parallel algorithms invoked with an execution policy object of type `execution::sequenced_policy` all occur in the calling thread of execution.

NOTE 3 The invocations are not interleaved; see 6.9.1.

The invocations of element access functions in parallel algorithms invoked with an execution policy object of type `execution::unsequenced_policy` are permitted to execute in an unordered fashion in the calling thread of execution, unsequenced with respect to one another in the calling thread of execution.

NOTE 4 This means that multiple function object invocations can be interleaved on a single thread of execution, which overrides the usual guarantee from 6.9.1 that function executions do not overlap with one another.

The behavior of a program is undefined if it invokes a vectorization-unsafe standard library function from user code called from an `execution::unsequenced_policy` algorithm.

NOTE 5 Because `execution::unsequenced_policy` allows the execution of element access functions to be interleaved on a single thread of execution, blocking synchronization, including the use of mutexes, risks deadlock.

The invocations of element access functions in parallel algorithms invoked with an execution policy object of type `execution::parallel_policy` are permitted to execute either in the invoking thread of execution or in a thread of execution implicitly created by the library to support parallel algorithm execution. If the threads of execution created by `thread` (33.4.3) or `jthread` (33.4.4) provide concurrent forward progress guarantees (6.9.2.3), then a thread of execution implicitly created by the library will provide parallel forward progress guarantees; otherwise, the provided forward progress guarantee is implementation-defined. Any such invocations executing in the same thread of execution are indeterminately sequenced with respect to each other.

NOTE 6 It is the caller's responsibility to ensure that the invocation does not introduce data races or deadlocks.

EXAMPLE 1

```
int a[] = {0,1};
std::vector<int> v;
std::for_each(std::execution::par, std::begin(a), std::end(a), [&](int i) {
    v.push_back(i*2+1);           // incorrect: data race
});
```

The program above has a data race because of the unsynchronized access to the container `v`.

EXAMPLE 2

```
std::atomic<int> x{0};
int a[] = {1,2};
std::for_each(std::execution::par, std::begin(a), std::end(a), [&](int) {
    x.fetch_add(1, std::memory_order::relaxed);
    // spin wait for another iteration to change the value of x
    while (x.load(std::memory_order::relaxed) == 1) { }           // incorrect: assumes execution order
});
```

The above example depends on the order of execution of the iterations, and will not terminate if both iterations are executed sequentially on the same thread of execution.

EXAMPLE 3

```
int x = 0;
std::mutex m;
int a[] = {1,2};
std::for_each(std::execution::par, std::begin(a), std::end(a), [&](int) {
    std::lock_guard<mutex> guard(m);
    ++x;
});
```

The above example synchronizes access to object `x` ensuring that it is incremented correctly.

The invocations of element access functions in parallel algorithms invoked with an execution policy object of type `execution::parallel_unsequenced_policy` are permitted to execute in an unordered fashion in unspecified threads of execution, and unsequenced with respect to one another within each thread of execution. These threads of execution are either the invoking thread of execution or threads of execution implicitly created by the library; the latter will provide weakly parallel forward progress guarantees.

NOTE 7 This means that multiple function object invocations can be interleaved on a single thread of execution, which overrides the usual guarantee from 6.9.1 that function executions do not overlap with one another.

The behavior of a program is undefined if it invokes a vectorization-unsafe standard library function from user code called from an `execution::parallel_unsequenced_policy` algorithm.

NOTE 8 Because `execution::parallel_unsequenced_policy` allows the execution of element access functions to be interleaved on a single thread of execution, blocking synchronization, including the use of mutexes, risks deadlock.

NOTE 9 The semantics of invocation with `execution::unsequenced_policy`, `execution::parallel_policy`, or `execution::parallel_unsequenced_policy` allow the implementation to fall back to sequential execution if the system is unable to parallelize an algorithm invocation, e.g., due to lack of resources.

If an invocation of a parallel algorithm uses threads of execution implicitly created by the library, then the invoking thread of execution will either

- temporarily block with forward progress guarantee delegation (6.9.2.3) on the completion of these library-managed threads of execution, or
- eventually execute an element access function;

the thread of execution will continue to do so until the algorithm is finished.

NOTE 10 In blocking with forward progress guarantee delegation in this context, a thread of execution created by the library is considered to have finished execution as soon as it has finished the execution of the particular element access function that the invoking thread of execution logically depends on.

The semantics of parallel algorithms invoked with an execution policy object of implementation-defined type are implementation-defined.

27.3.4 Parallel algorithm exceptions

[algorithms.parallel.exceptions]

During the execution of a parallel algorithm, if temporary memory resources are required for parallelization and none are available, the algorithm throws a `bad_alloc` exception.

During the execution of a parallel algorithm, if the invocation of an element access function exits via an uncaught exception, the behavior is determined by the `ExecutionPolicy`.

27.3.5 `ExecutionPolicy` algorithm overloads [algorithms.parallel.overloads]

Parallel algorithms are algorithm overloads. Each parallel algorithm overload has an additional template type parameter named `ExecutionPolicy`, which is the first template parameter. Additionally, each parallel algorithm overload has an additional function parameter of type `ExecutionPolicy&&`, which is the first function parameter.

NOTE Not all algorithms have parallel algorithm overloads.

Unless otherwise specified, the semantics of `ExecutionPolicy` algorithm overloads are identical to their overloads without.

Unless otherwise specified, the complexity requirements of `ExecutionPolicy` algorithm overloads are relaxed from the complexity requirements of the overloads without as follows: when the guarantee says “at most *expr*” or “exactly *expr*” and does not specify the number of assignments or swaps, and *expr* is not already expressed with $\mathcal{O}()$ notation, the complexity of the algorithm shall be $\mathcal{O}(expr)$.

Parallel algorithms shall not participate in overload resolution unless `is_execution_policy_v<remove_cvref_t<ExecutionPolicy>>` is true.

27.4 Header `<algorithm>` synopsis [algorithm.syn]

```
#include <initializer_list>           // see 17.10.2

    return {std::move(out), std::move(value)};
}
};
}

```

27.6 Non-modifying sequence operations

[alg.nonmodifying]

27.6.1 All of

[alg.all.of]

```

template<class InputIterator, class Predicate>
    constexpr bool all_of(InputIterator first, InputIterator last, Predicate pred);
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
    bool all_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
                Predicate pred);

template<input_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_unary_predicate<projected<I, Proj>> Pred>
    constexpr bool ranges::all_of(I first, S last, Pred pred, Proj proj = {});
template<input_range R, class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
    constexpr bool ranges::all_of(R&& r, Pred pred, Proj proj = {});

```

Let E be:

- `pred(*i)` for the overloads in namespace `std`;
- `invoke(pred, invoke(proj, *i))` for the overloads in namespace `ranges`.

Returns: `false` if E is `false` for some iterator i in the range $[first, last)$, and `true` otherwise.

Complexity: At most `last - first` applications of the predicate and any projection.

27.6.2 Any of

[alg.any.of]

```

template<class InputIterator, class Predicate>
    constexpr bool any_of(InputIterator first, InputIterator last, Predicate pred);
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
    bool any_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
                Predicate pred);

```

```
template<input_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr bool ranges::any_of(I first, S last, Pred pred, Proj proj = {});
template<input_range R, class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr bool ranges::any_of(R&& r, Pred pred, Proj proj = {});
```

Let E be:

- `pred(*i)` for the overloads in namespace `std`;
- `invoke(pred, invoke(proj, *i))` for the overloads in namespace `ranges`.

Returns: true if E is true for some iterator i in the range $[first, last)$, and false otherwise.

Complexity: At most `last - first` applications of the predicate and any projection.

27.6.3 None of

[alg.none.of]

```
template<class InputIterator, class Predicate>
constexpr bool none_of(InputIterator first, InputIterator last, Predicate pred);
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool none_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
             Predicate pred);
```

```
template<input_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr bool ranges::none_of(I first, S last, Pred pred, Proj proj = {});
template<input_range R, class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr bool ranges::none_of(R&& r, Pred pred, Proj proj = {});
```

Let E be:

- `pred(*i)` for the overloads in namespace `std`;
- `invoke(pred, invoke(proj, *i))` for the overloads in namespace `ranges`.

Returns: false if E is true for some iterator i in the range $[first, last)$, and true otherwise.

Complexity: At most `last - first` applications of the predicate and any projection.

27.6.4 Contains

[alg.contains]

```
template<input_iterator I, sentinel_for<I> S, class T, class Proj = identity>
requires indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T*>
constexpr bool ranges::contains(I first, S last, const T& value, Proj proj = {});
template<input_range R, class T, class Proj = identity>
requires indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T*>
constexpr bool ranges::contains(R&& r, const T& value, Proj proj = {});
```

Returns: `ranges::find(std::move(first), last, value, proj) != last`.

```
template<forward_iterator I1, sentinel_for<I1> S1,
        forward_iterator I2, sentinel_for<I2> S2,
        class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr bool ranges::contains_subrange(I1 first1, S1 last1, I2 first2, S2 last2,
                                         Pred pred = {}, Proj1 proj1 = {}, Proj2 proj2 = {});
template<forward_range R1, forward_range R2,
        class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr bool ranges::contains_subrange(R1&& r1, R2&& r2, Pred pred = {},
                                         Proj1 proj1 = {}, Proj2 proj2 = {});
```

Returns: `first2 == last2 || !ranges::search(first1, last1, first2, last2, pred, proj1, proj2).empty()`.

27.6.5 For each

[alg.foreach]

```
template<class InputIterator, class Function>
```

```
constexpr Function for_each(InputIterator first, InputIterator last, Function f);
```

Preconditions: Function meets the *Cpp17MoveConstructible* requirements (Table 31).

NOTE 1 Function need not meet the requirements of *Cpp17CopyConstructible* (Table 32).

Effects: Applies *f* to the result of dereferencing every iterator in the range [*first*,*last*), starting from *first* and proceeding to *last* - 1.

NOTE 2 If the type of *first* meets the requirements of a mutable iterator, *f* can apply non-constant functions through the dereferenced iterator.

Returns: *f*.

Complexity: Applies *f* exactly *last* - *first* times.

Remarks: If *f* returns a result, the result is ignored.

```
template<class ExecutionPolicy, class ForwardIterator, class Function>
```

```
void for_each(ExecutionPolicy&& exec,
              ForwardIterator first, ForwardIterator last,
              Function f);
```

Preconditions: Function meets the *Cpp17CopyConstructible* requirements.

Effects: Applies *f* to the result of dereferencing every iterator in the range [*first*,*last*).

NOTE 3 If the type of *first* meets the requirements of a mutable iterator, *f* can apply non-constant functions through the dereferenced iterator.

Complexity: Applies *f* exactly *last* - *first* times.

Remarks: If *f* returns a result, the result is ignored. Implementations do not have the freedom granted under 27.3.3 to make arbitrary copies of elements from the input sequence.

NOTE 4 Does not return a copy of its Function parameter, since parallelization often does not permit efficient state accumulation.

```
template<input_iterator I, sentinel_for<I> S, class Proj = identity,
        indirectly_unary_invocable<projected<I, Proj>> Fun>
```

```
constexpr ranges::for_each_result<I, Fun>
ranges::for_each(I first, S last, Fun f, Proj proj = {});
```

```
template<input_range R, class Proj = identity,
        indirectly_unary_invocable<projected<iterator_t<R>, Proj>> Fun>
constexpr ranges::for_each_result<borrowed_iterator_t<R>, Fun>
ranges::for_each(R&& r, Fun f, Proj proj = {});
```

Effects: Calls *invoke(f, invoke(proj, *i))* for every iterator *i* in the range [*first*,*last*), starting from *first* and proceeding to *last* - 1.

NOTE 5 If the result of *invoke(proj, *i)* is a mutable reference, *f* can apply non-constant functions.

Returns: {*last*, *std::move(f)*}.

Complexity: Applies *f* and *proj* exactly *last* - *first* times.

Remarks: If *f* returns a result, the result is ignored.

NOTE 6 The overloads in namespace *ranges* require *Fun* to model *copy_constructible*.

```
template<class InputIterator, class Size, class Function>
```

```
constexpr InputIterator for_each_n(InputIterator first, Size n, Function f);
```

Mandates: The type *Size* is convertible to an integral type (7.3.9, 11.4.8).

Preconditions: *n* >= 0 is true. Function meets the *Cpp17MoveConstructible* requirements.

NOTE 7 Function need not meet the requirements of *Cpp17CopyConstructible*.

Effects: Applies *f* to the result of dereferencing every iterator in the range [*first*,*first* + *n*) in order.

NOTE 8 If the type of *first* meets the requirements of a mutable iterator, *f* can apply non-constant functions through the dereferenced iterator.

Returns: `first + n`.

Remarks: If `f` returns a result, the result is ignored.

```
template<class ExecutionPolicy, class ForwardIterator, class Size, class Function>
ForwardIterator for_each_n(ExecutionPolicy&& exec, ForwardIterator first, Size n,
                          Function f);
```

Mandates: The type `Size` is convertible to an integral type (7.3.9, 11.4.8).

Preconditions: `n >= 0` is true. Function meets the *Cpp17CopyConstructible* requirements.

Effects: Applies `f` to the result of dereferencing every iterator in the range `[first, first + n)`.

NOTE 9 If the type of `first` meets the requirements of a mutable iterator, `f` can apply non-constant functions through the dereferenced iterator.

Returns: `first + n`.

Remarks: If `f` returns a result, the result is ignored. Implementations do not have the freedom granted under 27.3.3 to make arbitrary copies of elements from the input sequence.

```
template<input_iterator I, class Proj = identity,
        indirectly_unary_invocable<projected<I, Proj>> Fun>
constexpr ranges::for_each_n_result<I, Fun>
ranges::for_each_n(I first, iter_difference_t<I> n, Fun f, Proj proj = {});
```

Preconditions: `n >= 0` is true.

Effects: Calls `invoke(f, invoke(proj, *i))` for every iterator `i` in the range `[first, first + n)` in order.

NOTE 10 If the result of `invoke(proj, *i)` is a mutable reference, `f` can apply non-constant functions.

Returns: `{first + n, std::move(f)}`.

Remarks: If `f` returns a result, the result is ignored.

NOTE 11 The overload in namespace `ranges` requires `Fun` to model `copy_constructible`.

27.6.6 Find

[alg.find]

```
template<class InputIterator, class T>
constexpr InputIterator find(InputIterator first, InputIterator last,
                             const T& value);

template<class ExecutionPolicy, class ForwardIterator, class T>
ForwardIterator find(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
                    const T& value);

template<class InputIterator, class Predicate>
constexpr InputIterator find_if(InputIterator first, InputIterator last,
                                Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
ForwardIterator find_if(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
                      Predicate pred);

template<class InputIterator, class Predicate>
constexpr InputIterator find_if_not(InputIterator first, InputIterator last,
                                    Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
ForwardIterator find_if_not(ExecutionPolicy&& exec,
                          ForwardIterator first, ForwardIterator last,
                          Predicate pred);

template<input_iterator I, sentinel_for<I> S, class T, class Proj = identity>
requires indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T*>
constexpr I ranges::find(I first, S last, const T& value, Proj proj = {});

template<input_range R, class T, class Proj = identity>
requires indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T*>
constexpr borrowed_iterator_t<R>
ranges::find(R&& r, const T& value, Proj proj = {});
```

```

template<input_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr I ranges::find_if(I first, S last, Pred pred, Proj proj = {});
template<input_range R, class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr borrowed_iterator_t<R>
    ranges::find_if(R&& r, Pred pred, Proj proj = {});
template<input_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr I ranges::find_if_not(I first, S last, Pred pred, Proj proj = {});
template<input_range R, class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr borrowed_iterator_t<R>
    ranges::find_if_not(R&& r, Pred pred, Proj proj = {});

```

Let E be:

- $*i == \text{value}$ for `find`;
- $\text{pred}(*i) != \text{false}$ for `find_if`;
- $\text{pred}(*i) == \text{false}$ for `find_if_not`;
- $\text{bool}(\text{invoke}(\text{proj}, *i) == \text{value})$ for `ranges::find`;
- $\text{bool}(\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, *i)))$ for `ranges::find_if`;
- $\text{bool}(!\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, *i)))$ for `ranges::find_if_not`.

Returns: The first iterator i in the range $[\text{first}, \text{last})$ for which E is true. Returns `last` if no such iterator is found.

Complexity: At most `last - first` applications of the corresponding predicate and any projection.

27.6.7 Find last

[alg.find.last]

```

template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity>
requires indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T*>
constexpr subrange<I> ranges::find_last(I first, S last, const T& value, Proj proj = {});
template<forward_range R, class T, class Proj = identity>
requires indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T*>
constexpr borrowed_subrange_t<R> ranges::find_last(R&& r, const T& value, Proj proj = {});
template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr subrange<I> ranges::find_last_if(I first, S last, Pred pred, Proj proj = {});
template<forward_range R, class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr borrowed_subrange_t<R> ranges::find_last_if(R&& r, Pred pred, Proj proj = {});
template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr subrange<I> ranges::find_last_if_not(I first, S last, Pred pred, Proj proj = {});
template<forward_range R, class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr borrowed_subrange_t<R> ranges::find_last_if_not(R&& r, Pred pred, Proj proj = {});

```

Let E be:

- $\text{bool}(\text{invoke}(\text{proj}, *i) == \text{value})$ for `ranges::find_last`;
- $\text{bool}(\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, *i)))$ for `ranges::find_last_if`;
- $\text{bool}(!\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, *i)))$ for `ranges::find_last_if_not`.

Returns: Let i be the last iterator in the range $[\text{first}, \text{last})$ for which E is true. Returns $\{i, \text{last}\}$, or $\{\text{last}, \text{last}\}$ if no such iterator is found.

Complexity: At most `last - first` applications of the corresponding predicate and projection.

27.6.8 Find end

[alg.find.end]

```

template<class ForwardIterator1, class ForwardIterator2>
constexpr ForwardIterator1
    find_end(ForwardIterator1 first1, ForwardIterator1 last1,
             ForwardIterator2 first2, ForwardIterator2 last2);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator1
    find_end(ExecutionPolicy&& exec,
             ForwardIterator1 first1, ForwardIterator1 last1,
             ForwardIterator2 first2, ForwardIterator2 last2);

template<class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
constexpr ForwardIterator1
    find_end(ForwardIterator1 first1, ForwardIterator1 last1,
             ForwardIterator2 first2, ForwardIterator2 last2,
             BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
ForwardIterator1
    find_end(ExecutionPolicy&& exec,
             ForwardIterator1 first1, ForwardIterator1 last1,
             ForwardIterator2 first2, ForwardIterator2 last2,
             BinaryPredicate pred);

template<forward_iterator I1, sentinel_for<I1> S1, forward_iterator I2, sentinel_for<I2> S2,
         class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr subrange<I1>
    ranges::find_end(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {},
                    Proj1 proj1 = {}, Proj2 proj2 = {});
template<forward_range R1, forward_range R2,
         class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr borrowed_subrange_t<R1>
    ranges::find_end(R1&& r1, R2&& r2, Pred pred = {},
                    Proj1 proj1 = {}, Proj2 proj2 = {});

```

Let:

- `pred` be `equal_to{}` for the overloads with no parameter `pred`;
- E be:
 - `pred(*(i + n), *(first2 + n))` for the overloads in namespace `std`;
 - `invoke(pred, invoke(proj1, *(i + n)), invoke(proj2, *(first2 + n)))` for the overloads in namespace `ranges`;
- i be `last1` if `[first2, last2)` is empty, or if `(last2 - first2) > (last1 - first1)` is true, or if there is no iterator in the range `[first1, last1 - (last2 - first2))` such that for every non-negative integer $n < (last2 - first2)$, E is true. Otherwise i is the last such iterator in `[first1, last1 - (last2 - first2))`.

Returns:

- i for the overloads in namespace `std`.
- `{i, i + (i == last1 ? 0 : last2 - first2)}` for the overloads in namespace `ranges`.

Complexity: At most $(last2 - first2) * (last1 - first1 - (last2 - first2) + 1)$ applications of the corresponding predicate and any projections.

27.6.9 Find first

[alg.find.first.of]

```

template<class InputIterator, class ForwardIterator>
constexpr InputIterator
    find_first_of(InputIterator first1, InputIterator last1,
                  ForwardIterator first2, ForwardIterator last2);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator1
    find_first_of(ExecutionPolicy&& exec,
                  ForwardIterator1 first1, ForwardIterator1 last1,
                  ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator, class ForwardIterator,
         class BinaryPredicate>
constexpr InputIterator
    find_first_of(InputIterator first1, InputIterator last1,
                  ForwardIterator first2, ForwardIterator last2,
                  BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
ForwardIterator1
    find_first_of(ExecutionPolicy&& exec,
                  ForwardIterator1 first1, ForwardIterator1 last1,
                  ForwardIterator2 first2, ForwardIterator2 last2,
                  BinaryPredicate pred);

template<input_iterator I1, sentinel_for<I1> S1, forward_iterator I2, sentinel_for<I2> S2,
         class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr I1 ranges::find_first_of(I1 first1, S1 last1, I2 first2, S2 last2,
                                   Pred pred = {},
                                   Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, forward_range R2,
         class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr borrowed_iterator_t<R1>
    ranges::find_first_of(R1&& r1, R2&& r2,
                          Pred pred = {},
                          Proj1 proj1 = {}, Proj2 proj2 = {});

```

Let E be:

- $*i == *j$ for the overloads with no parameter `pred`;
- `pred(*i, *j) != false` for the overloads with a parameter `pred` and no parameter `proj1`;
- `bool(invoked(pred, invoke(proj1, *i), invoke(proj2, *j)))` for the overloads with parameters `pred` and `proj1`.

Effects: Finds an element that matches one of a set of values.

Returns: The first iterator i in the range $[first1, last1)$ such that for some iterator j in the range $[first2, last2)$ E holds. Returns `last1` if $[first2, last2)$ is empty or if no such iterator is found.

Complexity: At most $(last1 - first1) * (last2 - first2)$ applications of the corresponding predicate and any projections.

27.6.10 Adjacent find

[alg.adjacent.find]

```

template<class ForwardIterator>
constexpr ForwardIterator
    adjacent_find(ForwardIterator first, ForwardIterator last);
template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
    adjacent_find(ExecutionPolicy&& exec,
                  ForwardIterator first, ForwardIterator last);

```

```

template<class ForwardIterator, class BinaryPredicate>
constexpr ForwardIterator
adjacent_find(ForwardIterator first, ForwardIterator last,
              BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator, class BinaryPredicate>
ForwardIterator
adjacent_find(ExecutionPolicy&& exec,
              ForwardIterator first, ForwardIterator last,
              BinaryPredicate pred);

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_binary_predicate<projected<I, Proj>,
        projected<I, Proj>> Pred = ranges::equal_to>
constexpr I ranges::adjacent_find(I first, S last, Pred pred = {}, Proj proj = {});
template<forward_range R, class Proj = identity,
        indirect_binary_predicate<projected<iterator_t<R>, Proj>,
        projected<iterator_t<R>, Proj>> Pred = ranges::equal_to>
constexpr borrowed_iterator_t<R> ranges::adjacent_find(R&& r, Pred pred = {}, Proj proj = {});

```

Let E be:

- $*i == *(i + 1)$ for the overloads with no parameter `pred`;
- $\text{pred}(*i, *(i + 1)) != \text{false}$ for the overloads with a parameter `pred` and no parameter `proj`;
- $\text{bool}(\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, *i), \text{invoke}(\text{proj}, *(i + 1))))$ for the overloads with both parameters `pred` and `proj`.

Returns: The first iterator i such that both i and $i + 1$ are in the range $[\text{first}, \text{last})$ for which E holds. Returns `last` if no such iterator is found.

Complexity: For the overloads with no `ExecutionPolicy`, exactly

$$\min((i - \text{first}) + 1, (\text{last} - \text{first}) - 1)$$

applications of the corresponding predicate, where i is `adjacent_find`'s return value. For the overloads with an `ExecutionPolicy`, $\mathcal{O}(\text{last} - \text{first})$ applications of the corresponding predicate, and no more than twice as many applications of any projection.

27.6.11 Count

[alg.count]

```

template<class InputIterator, class T>
constexpr typename iterator_traits<InputIterator>::difference_type
count(InputIterator first, InputIterator last, const T& value);
template<class ExecutionPolicy, class ForwardIterator, class T>
typename iterator_traits<ForwardIterator>::difference_type
count(ExecutionPolicy&& exec,
      ForwardIterator first, ForwardIterator last, const T& value);

template<class InputIterator, class Predicate>
constexpr typename iterator_traits<InputIterator>::difference_type
count_if(InputIterator first, InputIterator last, Predicate pred);
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
typename iterator_traits<ForwardIterator>::difference_type
count_if(ExecutionPolicy&& exec,
          ForwardIterator first, ForwardIterator last, Predicate pred);

template<input_iterator I, sentinel_for<I> S, class T, class Proj = identity>
requires indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T*>
constexpr iter_difference_t<I>
ranges::count(I first, S last, const T& value, Proj proj = {});
template<input_range R, class T, class Proj = identity>
requires indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T*>
constexpr range_difference_t<R>
ranges::count(R&& r, const T& value, Proj proj = {});

```

```

template<input_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr iter_difference_t<I>
    ranges::count_if(I first, S last, Pred pred, Proj proj = {});
template<input_range R, class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr range_difference_t<R>
    ranges::count_if(R&& r, Pred pred, Proj proj = {});

```

Let E be:

- $*i == \text{value}$ for the overloads with no parameter `pred` or `proj`;
- $\text{pred}(*i) != \text{false}$ for the overloads with a parameter `pred` but no parameter `proj`;
- $\text{invoke}(\text{proj}, *i) == \text{value}$ for the overloads with a parameter `proj` but no parameter `pred`;
- $\text{bool}(\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, *i)))$ for the overloads with both parameters `proj` and `pred`.

Effects: Returns the number of iterators i in the range $[\text{first}, \text{last})$ for which E holds.

Complexity: Exactly $\text{last} - \text{first}$ applications of the corresponding predicate and any projection.

27.6.12 Mismatch

[mismatch]

```

template<class InputIterator1, class InputIterator2>
constexpr pair<InputIterator1, InputIterator2>
    mismatch(InputIterator1 first1, InputIterator1 last1,
             InputIterator2 first2);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
pair<ForwardIterator1, ForwardIterator2>
    mismatch(ExecutionPolicy&& exec,
             ForwardIterator1 first1, ForwardIterator1 last1,
             ForwardIterator2 first2);

template<class InputIterator1, class InputIterator2,
        class BinaryPredicate>
constexpr pair<InputIterator1, InputIterator2>
    mismatch(InputIterator1 first1, InputIterator1 last1,
             InputIterator2 first2, BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class BinaryPredicate>
pair<ForwardIterator1, ForwardIterator2>
    mismatch(ExecutionPolicy&& exec,
             ForwardIterator1 first1, ForwardIterator1 last1,
             ForwardIterator2 first2, BinaryPredicate pred);

template<class InputIterator1, class InputIterator2>
constexpr pair<InputIterator1, InputIterator2>
    mismatch(InputIterator1 first1, InputIterator1 last1,
             InputIterator2 first2, InputIterator2 last2);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
pair<ForwardIterator1, ForwardIterator2>
    mismatch(ExecutionPolicy&& exec,
             ForwardIterator1 first1, ForwardIterator1 last1,
             ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator1, class InputIterator2,
        class BinaryPredicate>
constexpr pair<InputIterator1, InputIterator2>
    mismatch(InputIterator1 first1, InputIterator1 last1,
             InputIterator2 first2, InputIterator2 last2,
             BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class BinaryPredicate>
pair<ForwardIterator1, ForwardIterator2>
    mismatch(ExecutionPolicy&& exec,

```

```
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
BinaryPredicate pred);
```

```
template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
        class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr ranges::mismatch_result<I1, I2>
    ranges::mismatch(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {},
                    Proj1 proj1 = {}, Proj2 proj2 = {});
template<input_range R1, input_range R2,
        class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr ranges::mismatch_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>>
    ranges::mismatch(R1&& r1, R2&& r2, Pred pred = {},
                    Proj1 proj1 = {}, Proj2 proj2 = {});
```

Let `last2` be `first2 + (last1 - first1)` for the overloads with no parameter `last2` or `r2`.

Let E be:

- `!(*(first1 + n) == *(first2 + n))` for the overloads with no parameter `pred`;
- `pred(*(first1 + n), *(first2 + n)) == false` for the overloads with a parameter `pred` and no parameter `proj1`;
- `!invoke(pred, invoke(proj1, *(first1 + n)), invoke(proj2, *(first2 + n)))` for the overloads with both parameters `pred` and `proj1`.

Let N be `min(last1 - first1, last2 - first2)`.

Returns: `{ first1 + n, first2 + n }`, where n is the smallest integer in $[0, N)$ such that E holds, or N if no such integer exists.

Complexity: At most N applications of the corresponding predicate and any projections.

27.6.13 Equal

[alg.equal]

```
template<class InputIterator1, class InputIterator2>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
                    InputIterator2 first2);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool equal(ExecutionPolicy&& exec,
           ForwardIterator1 first1, ForwardIterator1 last1,
           ForwardIterator2 first2);

template<class InputIterator1, class InputIterator2,
        class BinaryPredicate>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
                    InputIterator2 first2, BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class BinaryPredicate>
bool equal(ExecutionPolicy&& exec,
           ForwardIterator1 first1, ForwardIterator1 last1,
           ForwardIterator2 first2, BinaryPredicate pred);

template<class InputIterator1, class InputIterator2>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
                    InputIterator2 first2, InputIterator2 last2);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool equal(ExecutionPolicy&& exec,
           ForwardIterator1 first1, ForwardIterator1 last1,
           ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator1, class InputIterator2,
        class BinaryPredicate>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
                    InputIterator2 first2, InputIterator2 last2,
```

```

        BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class BinaryPredicate>
bool equal(ExecutionPolicy&& exec,
           ForwardIterator1 first1, ForwardIterator1 last1,
           ForwardIterator2 first2, ForwardIterator2 last2,
           BinaryPredicate pred);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
        class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr bool ranges::equal(I1 first1, S1 last1, I2 first2, S2 last2,
                             Pred pred = {},
                             Proj1 proj1 = {}, Proj2 proj2 = {});
template<input_range R1, input_range R2, class Pred = ranges::equal_to,
        class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr bool ranges::equal(R1&& r1, R2&& r2, Pred pred = {},
                             Proj1 proj1 = {}, Proj2 proj2 = {});

```

Let:

- last2 be first2 + (last1 - first1) for the overloads with no parameter last2 or r2;
- pred be equal_to{} for the overloads with no parameter pred;
- *E* be:
 - pred(*i, *(first2 + (i - first1))) for the overloads with no parameter proj1;
 - invoke(pred, invoke(proj1, *i), invoke(proj2, *(first2 + (i - first1)))) for the overloads with parameter proj1.

Returns: If last1 - first1 != last2 - first2, return false. Otherwise return true if *E* holds for every iterator *i* in the range [first1, last1). Otherwise, returns false.

Complexity: If

- the types of first1, last1, first2, and last2 meet the *Cpp17RandomAccessIterator* requirements (25.3.5.7) and last1 - first1 != last2 - first2 for the overloads in namespace std;
- the types of first1, last1, first2, and last2 pairwise model sized_sentinel_for (25.3.4.8) and last1 - first1 != last2 - first2 for the first overload in namespace ranges,
- R1 and R2 each model sized_range and ranges::distance(r1) != ranges::distance(r2) for the second overload in namespace ranges,

then no applications of the corresponding predicate and each projection; otherwise,

- For the overloads with no ExecutionPolicy, at most min(last1 - first1, last2 - first2) applications of the corresponding predicate and any projections.
- For the overloads with an ExecutionPolicy, $\mathcal{O}(\min(\text{last1} - \text{first1}, \text{last2} - \text{first2}))$ applications of the corresponding predicate.

27.6.14 Is permutation

[alg.is.permutation]

```

template<class ForwardIterator1, class ForwardIterator2>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
                             ForwardIterator2 first2);
template<class ForwardIterator1, class ForwardIterator2,
        class BinaryPredicate>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
                             ForwardIterator2 first2, BinaryPredicate pred);
template<class ForwardIterator1, class ForwardIterator2>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
                             ForwardIterator2 first2, ForwardIterator2 last2);
template<class ForwardIterator1, class ForwardIterator2,
        class BinaryPredicate>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
                             ForwardIterator2 first2, ForwardIterator2 last2,

```

BinaryPredicate pred);

Let `last2` be `first2 + (last1 - first1)` for the overloads with no parameter named `last2`, and let `pred` be `equal_to{}` for the overloads with no parameter `pred`.

Mandates: `ForwardIterator1` and `ForwardIterator2` have the same value type.

Preconditions: The comparison function is an equivalence relation.

Returns: If `last1 - first1 != last2 - first2`, return `false`. Otherwise return `true` if there exists a permutation of the elements in the range `[first2, last2)`, beginning with `ForwardIterator2 begin`, such that `equal(first1, last1, begin, pred)` returns `true`; otherwise, returns `false`.

Complexity: No applications of the corresponding predicate if `ForwardIterator1` and `ForwardIterator2` meet the requirements of random access iterators and `last1 - first1 != last2 - first2`. Otherwise, exactly `last1 - first1` applications of the corresponding predicate if `equal(first1, last1, first2, last2, pred)` would return `true`; otherwise, at worst $\mathcal{O}(N^2)$, where N has the value `last1 - first1`.

```
template<forward_iterator I1, sentinel_for<I1> S1, forward_iterator I2,
        sentinel_for<I2> S2, class Proj1 = identity, class Proj2 = identity,
        indirect_equivalence_relation<projected<I1, Proj1>,
        projected<I2, Proj2>> Pred = ranges::equal_to>
constexpr bool ranges::is_permutation(I1 first1, S1 last1, I2 first2, S2 last2,
        Pred pred = {},
        Proj1 proj1 = {}, Proj2 proj2 = {});

template<forward_range R1, forward_range R2,
        class Proj1 = identity, class Proj2 = identity,
        indirect_equivalence_relation<projected<iterator_t<R1>, Proj1>,
        projected<iterator_t<R2>, Proj2>> Pred = ranges::equal_to>
constexpr bool ranges::is_permutation(R1&& r1, R2&& r2, Pred pred = {},
        Proj1 proj1 = {}, Proj2 proj2 = {});
```

Returns: If `last1 - first1 != last2 - first2`, return `false`. Otherwise return `true` if there exists a permutation of the elements in the range `[first2, last2)`, bounded by `[pfirst, plast)`, such that `ranges::equal(first1, last1, pfirst, plast, pred, proj1, proj2)` returns `true`; otherwise, returns `false`.

Complexity: No applications of the corresponding predicate and projections if

- for the first overload,
 - `S1` and `I1` model `sized_sentinel_for<S1, I1>`,
 - `S2` and `I2` model `sized_sentinel_for<S2, I2>`, and
 - `last1 - first1 != last2 - first2`;
- for the second overload, `R1` and `R2` each model `sized_range`, and `ranges::distance(r1) != ranges::distance(r2)`.

Otherwise, exactly `last1 - first1` applications of the corresponding predicate and projections if `ranges::equal(first1, last1, first2, last2, pred, proj1, proj2)` would return `true`; otherwise, at worst $\mathcal{O}(N^2)$, where N has the value `last1 - first1`.

27.6.15 Search

[alg.search]

```
template<class ForwardIterator1, class ForwardIterator2>
constexpr ForwardIterator1
search(ForwardIterator1 first1, ForwardIterator1 last1,
        ForwardIterator2 first2, ForwardIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator1
search(ExecutionPolicy&& exec,
        ForwardIterator1 first1, ForwardIterator1 last1,
        ForwardIterator2 first2, ForwardIterator2 last2);
```

```

template<class ForwardIterator1, class ForwardIterator2,
        class BinaryPredicate>
constexpr ForwardIterator1
search(ForwardIterator1 first1, ForwardIterator1 last1,
       ForwardIterator2 first2, ForwardIterator2 last2,
       BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class BinaryPredicate>
ForwardIterator1
search(ExecutionPolicy&& exec,
       ForwardIterator1 first1, ForwardIterator1 last1,
       ForwardIterator2 first2, ForwardIterator2 last2,
       BinaryPredicate pred);

```

Returns: The first iterator i in the range $[first1, last1 - (last2 - first2))$ such that for every non-negative integer n less than $last2 - first2$ the following corresponding conditions hold: $*(i + n) == *(first2 + n)$, $pred(*(i + n), *(first2 + n)) != false$. Returns $first1$ if $[first2, last2)$ is empty, otherwise returns $last1$ if no such iterator is found.

Complexity: At most $(last1 - first1) * (last2 - first2)$ applications of the corresponding predicate.

```

template<forward_iterator I1, sentinel_for<I1> S1, forward_iterator I2,
        sentinel_for<I2> S2, class Pred = ranges::equal_to,
        class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr subrange<I1>
ranges::search(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {},
               Proj1 proj1 = {}, Proj2 proj2 = {});
template<forward_range R1, forward_range R2, class Pred = ranges::equal_to,
        class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr borrowed_subrange_t<R1>
ranges::search(R1&& r1, R2&& r2, Pred pred = {},
               Proj1 proj1 = {}, Proj2 proj2 = {});

```

Returns:

- $\{i, i + (last2 - first2)\}$: where i is the first iterator in the range $[first1, last1 - (last2 - first2))$ such that for every non-negative integer n less than $last2 - first2$ the condition $bool(\text{invoke}(\text{pred}, \text{invoke}(\text{proj1}, *(i + n)), \text{invoke}(\text{proj2}, *(first2 + n))))$ is true.
- Returns $\{last1, last1\}$ if no such iterator exists.

Complexity: At most $(last1 - first1) * (last2 - first2)$ applications of the corresponding predicate and projections.

```

template<class ForwardIterator, class Size, class T>
constexpr ForwardIterator
search_n(ForwardIterator first, ForwardIterator last,
         Size count, const T& value);
template<class ExecutionPolicy, class ForwardIterator, class Size, class T>
ForwardIterator
search_n(ExecutionPolicy&& exec,
         ForwardIterator first, ForwardIterator last,
         Size count, const T& value);

template<class ForwardIterator, class Size, class T,
        class BinaryPredicate>
constexpr ForwardIterator
search_n(ForwardIterator first, ForwardIterator last,
         Size count, const T& value,
         BinaryPredicate pred);

```

```
template<class ExecutionPolicy, class ForwardIterator, class Size, class T,
        class BinaryPredicate>
ForwardIterator
search_n(ExecutionPolicy&& exec,
        ForwardIterator first, ForwardIterator last,
        Size count, const T& value,
        BinaryPredicate pred);
```

Mandates: The type `Size` is convertible to an integral type (7.3.9, 11.4.8).

Returns: The first iterator `i` in the range `[first, last - count)` such that for every non-negative integer `n` less than `count` the following corresponding conditions hold: `*(i + n) == value`, `pred(*(i + n), value) != false`. Returns `last` if no such iterator is found.

Complexity: At most `last - first` applications of the corresponding predicate.

```
template<forward_iterator I, sentinel_for<I> S, class T,
        class Pred = ranges::equal_to, class Proj = identity>
requires indirectly_comparable<I, const T*, Pred, Proj>
constexpr subrange<I>
ranges::search_n(I first, S last, iter_difference_t<I> count,
        const T& value, Pred pred = {}, Proj proj = {});
template<forward_range R, class T, class Pred = ranges::equal_to,
        class Proj = identity>
requires indirectly_comparable<iterator_t<R>, const T*, Pred, Proj>
constexpr borrowed_subrange_t<R>
ranges::search_n(R&& r, range_difference_t<R> count,
        const T& value, Pred pred = {}, Proj proj = {});
```

Returns: `{i, i + count}` where `i` is the first iterator in the range `[first, last - count)` such that for every non-negative integer `n` less than `count`, the following condition holds: `invoke(pred, invoke(proj, *(i + n)), value)`. Returns `{last, last}` if no such iterator is found.

Complexity: At most `last - first` applications of the corresponding predicate and projection.

```
template<class ForwardIterator, class Searcher>
constexpr ForwardIterator
search(ForwardIterator first, ForwardIterator last, const Searcher& searcher);
```

Effects: Equivalent to: `return searcher(first, last).first;`

Remarks: `Searcher` need not meet the `Cpp17CopyConstructible` requirements.

27.6.16 Starts with

[alg.starts.with]

```
template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
        class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr bool ranges::starts_with(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {},
        Proj1 proj1 = {}, Proj2 proj2 = {});
template<input_range R1, input_range R2, class Pred = ranges::equal_to, class Proj1 = identity,
        class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr bool ranges::starts_with(R1&& r1, R2&& r2, Pred pred = {},
        Proj1 proj1 = {}, Proj2 proj2 = {});
```

Returns:

```
ranges::mismatch(std::move(first1), last1, std::move(first2), last2,
        pred, proj1, proj2).in2 == last2
```

27.6.17 Ends with

[alg.ends.with]

```
template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
        class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires (forward_iterator<I1> || sized_sentinel_for<S1, I1>) &&
        (forward_iterator<I2> || sized_sentinel_for<S2, I2>) &&
        indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr bool ranges::ends_with(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {},
```

```
Proj1 proj1 = {}, Proj2 proj2 = {});
```

Let N1 be last1 - first1 and N2 be last2 - first2.

Returns: false if N1 < N2, otherwise

```
ranges::equal(std::move(first1) + (N1 - N2), last1, std::move(first2), last2,
              pred, proj1, proj2)
```

```
template<input_range R1, input_range R2, class Pred = ranges::equal_to, class Proj1 = identity,
        class Proj2 = identity>
requires (forward_range<R1> || sized_range<R1>) &&
         (forward_range<R2> || sized_range<R2>) &&
         indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr bool ranges::ends_with(R1&& r1, R2&& r2, Pred pred = {},
                                Proj1 proj1 = {}, Proj2 proj2 = {});
```

Let N1 be ranges::distance(r1) and N2 be ranges::distance(r2).

Returns: false if N1 < N2, otherwise

```
ranges::equal(ranges::drop_view(ranges::ref_view(r1), N1 - N2), r2, pred, proj1, proj2)
```

27.6.18 Fold

[alg.fold]

```
template<input_iterator I, sentinel_for<I> S, class T, indirectly_binary_left_foldable<T, I> F>
constexpr auto ranges::fold_left(I first, S last, T init, F f);
template<input_range R, class T, indirectly_binary_left_foldable<T, iterator_t<R>> F>
constexpr auto ranges::fold_left(R&& r, T init, F f);
```

Returns:

```
ranges::fold_left_with_iter(std::move(first), last, std::move(init), f).value
```

```
template<input_iterator I, sentinel_for<I> S,
        indirectly_binary_left_foldable<iter_value_t<I>, I> F>
requires constructible_from<iter_value_t<I>, iter_reference_t<I>>
constexpr auto ranges::fold_left_first(I first, S last, F f);
template<input_range R, indirectly_binary_left_foldable<range_value_t<R>, iterator_t<R>> F>
requires constructible_from<range_value_t<R>, range_reference_t<R>>
constexpr auto ranges::fold_left_first(R&& r, F f);
```

Returns:

```
ranges::fold_left_first_with_iter(std::move(first), last, f).value
```

```
template<bidirectional_iterator I, sentinel_for<I> S, class T,
        indirectly_binary_right_foldable<T, I> F>
constexpr auto ranges::fold_right(I first, S last, T init, F f);
template<bidirectional_range R, class T,
        indirectly_binary_right_foldable<T, iterator_t<R>> F>
constexpr auto ranges::fold_right(R&& r, T init, F f);
```

Effects: Equivalent to:

```
using U = decay_t<invoke_result_t<F&, iter_reference_t<I>, T>>;
if (first == last)
    return U(std::move(init));
I tail = ranges::next(first, last);
U accum = invoke(f, *--tail, std::move(init));
while (first != tail)
    accum = invoke(f, *--tail, std::move(accum));
return accum;
```

```
template<bidirectional_iterator I, sentinel_for<I> S,
        indirectly_binary_right_foldable<iter_value_t<I>, I> F>
requires constructible_from<iter_value_t<I>, iter_reference_t<I>>
constexpr auto ranges::fold_right_last(I first, S last, F f);
template<bidirectional_range R,
        indirectly_binary_right_foldable<range_value_t<R>, iterator_t<R>> F>
requires constructible_from<range_value_t<R>, range_reference_t<R>>
```

```
constexpr auto ranges::fold_right_last(R&& r, F f);
```

Let U be `decltype(ranges::fold_right(first, last, iter_value_t<I>(*first), f))`.

Effects: Equivalent to:

```
if (first == last)
    return optional<U>();
I tail = ranges::prev(ranges::next(first, std::move(last)));
return optional<U>(in_place,
    ranges::fold_right(std::move(first), tail, iter_value_t<I>(*tail), std::move(f)));
```

```
template<input_iterator I, sentinel_for<I> S, class T,
    indirectly_binary_left_foldable<T, I> F>
```

```
constexpr see below ranges::fold_left_with_iter(I first, S last, T init, F f);
```

```
template<input_range R, class T, indirectly_binary_left_foldable<T, iterator_t<R>> F>
```

```
constexpr see below ranges::fold_left_with_iter(R&& r, T init, F f);
```

Let U be `decay_t<invoke_result_t<F&, T, iter_reference_t<I>>>`.

Effects: Equivalent to:

```
if (first == last)
    return {std::move(first), U(std::move(init))};
U accum = invoke(f, std::move(init), *first);
for (++first; first != last; ++first)
    accum = invoke(f, std::move(accum), *first);
return {std::move(first), std::move(accum)};
```

Remarks: The return type is `fold_left_with_iter_result<I, U>` for the first overload and `fold_left_with_iter_result<borrowed_iterator_t<R>, U>` for the second overload.

```
template<input_iterator I, sentinel_for<I> S,
```

```
    indirectly_binary_left_foldable<iter_value_t<I>, I> F>
```

```
requires constructible_from<iter_value_t<I>, iter_reference_t<I>>
```

```
constexpr see below ranges::fold_left_first_with_iter(I first, S last, F f);
```

```
template<input_range R, indirectly_binary_left_foldable<range_value_t<R>, iterator_t<R>> F>
```

```
requires constructible_from<range_value_t<R>, range_reference_t<R>>
```

```
constexpr see below ranges::fold_left_first_with_iter(R&& r, F f);
```

Let U be

```
decltype(ranges::fold_left(std::move(first), last, iter_value_t<I>(*first), f))
```

Effects: Equivalent to:

```
if (first == last)
    return {std::move(first), optional<U>()};
optional<U> init(in_place, *first);
for (++first; first != last; ++first)
    *init = invoke(f, std::move(*init), *first);
return {std::move(first), std::move(init)};
```

Remarks: The return type is `fold_left_first_with_iter_result<I, optional<U>>` for the first overload and `fold_left_first_with_iter_result<borrowed_iterator_t<R>, optional<U>>` for the second overload.

27.7 Mutating sequence operations

[alg.modifying.operations]

27.7.1 Copy

[alg.copy]

```
template<class InputIterator, class OutputIterator>
```

```
constexpr OutputIterator copy(InputIterator first, InputIterator last,
    OutputIterator result);
```

```
template<input_iterator I, sentinel_for<I> S, weakly_incrementable O>
```

```
requires indirectly_copyable<I, O>
```

```
constexpr ranges::copy_result<I, O> ranges::copy(I first, S last, O result);
```

```
template<input_range R, weakly_incrementable O>
requires indirectly_copyable<iterator_t<R>, O>
constexpr ranges::copy_result<borrowed_iterator_t<R>, O> ranges::copy(R&& r, O result);
```

Let N be `last - first`.

Preconditions: `result` is not in the range `[first, last)`.

Effects: Copies elements in the range `[first, last)` into the range `[result, result + N)` starting from `first` and proceeding to `last`. For each non-negative integer $n < N$, performs `*(result + n) = *(first + n)`.

Returns:

- `result + N` for the overload in namespace `std`.
- `{last, result + N}` for the overloads in namespace `ranges`.

Complexity: Exactly N assignments.

```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 copy(ExecutionPolicy&& policy,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result);
```

Preconditions: The ranges `[first, last)` and `[result, result + (last - first))` do not overlap.

Effects: Copies elements in the range `[first, last)` into the range `[result, result + (last - first))`. For each non-negative integer $n < (last - first)$, performs `*(result + n) = *(first + n)`.

Returns: `result + (last - first)`.

Complexity: Exactly `last - first` assignments.

```
template<class InputIterator, class Size, class OutputIterator>
constexpr OutputIterator copy_n(InputIterator first, Size n,
    OutputIterator result);
template<class ExecutionPolicy, class ForwardIterator1, class Size, class ForwardIterator2>
ForwardIterator2 copy_n(ExecutionPolicy&& exec,
    ForwardIterator1 first, Size n,
    ForwardIterator2 result);
```

```
template<input_iterator I, weakly_incrementable O>
requires indirectly_copyable<I, O>
constexpr ranges::copy_n_result<I, O>
ranges::copy_n(I first, iter_difference_t<I> n, O result);
```

Let N be `max(0, n)`.

Mandates: The type `Size` is convertible to an integral type (7.3.9, 11.4.8).

Effects: For each non-negative integer $i < N$, performs `*(result + i) = *(first + i)`.

Returns:

- `result + N` for the overloads in namespace `std`.
- `{first + N, result + N}` for the overload in namespace `ranges`.

Complexity: Exactly N assignments.

```
template<class InputIterator, class OutputIterator, class Predicate>
constexpr OutputIterator copy_if(InputIterator first, InputIterator last,
    OutputIterator result, Predicate pred);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
    class Predicate>
ForwardIterator2 copy_if(ExecutionPolicy&& exec,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result, Predicate pred);
```

```
template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, class Proj = identity,
    indirect_unary_predicate<projected<I, Proj>> Pred>
requires indirectly_copyable<I, O>
```

```
constexpr ranges::copy_if_result<I, O>
  ranges::copy_if(I first, S last, O result, Pred pred, Proj proj = {});
template<input_range R, weakly_incrementable O, class Proj = identity,
  indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
  requires indirectly_copyable<iterator_t<R>, O>
constexpr ranges::copy_if_result<borrowed_iterator_t<R>, O>
  ranges::copy_if(R&& r, O result, Pred pred, Proj proj = {});
```

Let E be:

- `bool(pred(*i))` for the overloads in namespace `std`;
- `bool(invoker(pred, invoker(proj, *i)))` for the overloads in namespace `ranges`,

and N be the number of iterators i in the range $[first, last)$ for which the condition E holds.

Preconditions: The ranges $[first, last)$ and $[result, result + (last - first))$ do not overlap.

NOTE For the overload with an `ExecutionPolicy`, a performance cost is possible if `iterator_traits<ForwardIterator1>::value_type` is not `Cpp17MoveConstructible` (Table 31).

Effects: Copies all of the elements referred to by the iterator i in the range $[first, last)$ for which E is true.

Returns:

- `result + N` for the overloads in namespace `std`.
- `{last, result + N}` for the overloads in namespace `ranges`.

Complexity: Exactly $last - first$ applications of the corresponding predicate and any projection.

Remarks: Stable (16.4.6.8).

```
template<class BidirectionalIterator1, class BidirectionalIterator2>
constexpr BidirectionalIterator2
  copy_backward(BidirectionalIterator1 first,
    BidirectionalIterator1 last,
    BidirectionalIterator2 result);

template<bidirectional_iterator I1, sentinel_for<I1> S1, bidirectional_iterator I2>
  requires indirectly_copyable<I1, I2>
constexpr ranges::copy_backward_result<I1, I2>
  ranges::copy_backward(I1 first, S1 last, I2 result);
template<bidirectional_range R, bidirectional_iterator I>
  requires indirectly_copyable<iterator_t<R>, I>
constexpr ranges::copy_backward_result<borrowed_iterator_t<R>, I>
  ranges::copy_backward(R&& r, I result);
```

Let N be $last - first$.

Preconditions: `result` is not in the range $(first, last]$.

Effects: Copies elements in the range $[first, last)$ into the range $[result - N, result)$ starting from $last - 1$ and proceeding to $first$.²¹⁵ For each positive integer $n \leq N$, performs $*(result - n) = *(last - n)$.

Returns:

- `result - N` for the overload in namespace `std`.
- `{last, result - N}` for the overloads in namespace `ranges`.

Complexity: Exactly N assignments.

27.7.2 Move

[alg.move]

```
template<class InputIterator, class OutputIterator>
constexpr OutputIterator move(InputIterator first, InputIterator last,
  OutputIterator result);
```

²¹⁵) `copy_backward` can be used instead of `copy` when $last$ is in the range $[result - N, result)$.

```

template<input_iterator I, sentinel_for<I> S, weakly_incrementable O>
requires indirectly_movable<I, O>
constexpr ranges::move_result<I, O>
    ranges::move(I first, S last, O result);
template<input_range R, weakly_incrementable O>
requires indirectly_movable<iterator_t<R>, O>
constexpr ranges::move_result<borrowed_iterator_t<R>, O>
    ranges::move(R&& r, O result);

```

Let E be

- `std::move(*(first + n))` for the overload in namespace `std`;
- `ranges::iter_move(first + n)` for the overloads in namespace `ranges`.

Let N be `last - first`.

Preconditions: `result` is not in the range `[first, last)`.

Effects: Moves elements in the range `[first, last)` into the range `[result, result + N)` starting from `first` and proceeding to `last`. For each non-negative integer $n < N$, performs `*(result + n) = E`.

Returns:

- `result + N` for the overload in namespace `std`.
- `{last, result + N}` for the overloads in namespace `ranges`.

Complexity: Exactly N assignments.

```

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 move(ExecutionPolicy&& policy,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result);

```

Let N be `last - first`.

Preconditions: The ranges `[first, last)` and `[result, result + N)` do not overlap.

Effects: Moves elements in the range `[first, last)` into the range `[result, result + N)`. For each non-negative integer $n < N$, performs `*(result + n) = std::move(*(first + n))`.

Returns: `result + N`.

Complexity: Exactly N assignments.

```

template<class BidirectionalIterator1, class BidirectionalIterator2>
constexpr BidirectionalIterator2
    move_backward(BidirectionalIterator1 first, BidirectionalIterator1 last,
    BidirectionalIterator2 result);

```

```

template<bidirectional_iterator I1, sentinel_for<I1> S1, bidirectional_iterator I2>
requires indirectly_movable<I1, I2>
constexpr ranges::move_backward_result<I1, I2>
    ranges::move_backward(I1 first, S1 last, I2 result);
template<bidirectional_range R, bidirectional_iterator I>
requires indirectly_movable<iterator_t<R>, I>
constexpr ranges::move_backward_result<borrowed_iterator_t<R>, I>
    ranges::move_backward(R&& r, I result);

```

Let E be

- `std::move(*(last - n))` for the overload in namespace `std`;
- `ranges::iter_move(last - n)` for the overloads in namespace `ranges`.

Let N be `last - first`.

Preconditions: `result` is not in the range `(first, last]`.

Effects: Moves elements in the range `[first, last)` into the range `[result - N, result)` starting from `last - 1` and proceeding to `first`.²¹⁶ For each positive integer $n \leq N$, performs `*(result - n) = E`.

²¹⁶⁾ `move_backward` can be used instead of `move` when `last` is in the range `[result - N, result)`.

Returns:

- `result` - N for the overload in namespace `std`.
- `{last, result - N}` for the overloads in namespace `ranges`.

Complexity: Exactly N assignments.

27.7.3 Swap

[alg.swap]

```
template<class ForwardIterator1, class ForwardIterator2>
constexpr ForwardIterator2
    swap_ranges(ForwardIterator1 first1, ForwardIterator1 last1,
                ForwardIterator2 first2);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
    swap_ranges(ExecutionPolicy&& exec,
                ForwardIterator1 first1, ForwardIterator1 last1,
                ForwardIterator2 first2);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2>
requires indirectly_swappable<I1, I2>
constexpr ranges::swap_ranges_result<I1, I2>
    ranges::swap_ranges(I1 first1, S1 last1, I2 first2, S2 last2);
template<input_range R1, input_range R2>
requires indirectly_swappable<iterator_t<R1>, iterator_t<R2>>
constexpr ranges::swap_ranges_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>>
    ranges::swap_ranges(R1&& r1, R2&& r2);
```

Let:

- `last2` be `first2 + (last1 - first1)` for the overloads with no parameter named `last2`;
- M be $\min(\text{last1} - \text{first1}, \text{last2} - \text{first2})$.

Preconditions: The two ranges `[first1, last1)` and `[first2, last2)` do not overlap. For the overloads in namespace `std`, `*(first1 + n)` is swappable with `(16.4.4.3) *(first2 + n)`.

Effects: For each non-negative integer $n < M$ performs:

- `swap(*(first1 + n), *(first2 + n))` for the overloads in namespace `std`;
- `ranges::iter_swap(first1 + n, first2 + n)` for the overloads in namespace `ranges`.

Returns:

- `last2` for the overloads in namespace `std`.
- `{first1 + M, first2 + M}` for the overloads in namespace `ranges`.

Complexity: Exactly M swaps.

```
template<class ForwardIterator1, class ForwardIterator2>
constexpr void iter_swap(ForwardIterator1 a, ForwardIterator2 b);

Preconditions: a and b are dereferenceable. *a is swappable with (16.4.4.3) *b.

Effects: As if by swap(*a, *b).
```

27.7.4 Transform

[alg.transform]

```
template<class InputIterator, class OutputIterator,
        class UnaryOperation>
constexpr OutputIterator
    transform(InputIterator first1, InputIterator last1,
              OutputIterator result, UnaryOperation op);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class UnaryOperation>
ForwardIterator2
    transform(ExecutionPolicy&& exec,
              ForwardIterator1 first1, ForwardIterator1 last1,
              ForwardIterator2 result, UnaryOperation op);
```

```

template<class InputIterator1, class InputIterator2,
        class OutputIterator, class BinaryOperation>
constexpr OutputIterator
    transform(InputIterator1 first1, InputIterator1 last1,
              InputIterator2 first2, OutputIterator result,
              BinaryOperation binary_op);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class ForwardIterator, class BinaryOperation>
ForwardIterator
    transform(ExecutionPolicy&& exec,
              ForwardIterator1 first1, ForwardIterator1 last1,
              ForwardIterator2 first2, ForwardIterator result,
              BinaryOperation binary_op);

template<input_iterator I, sentinel_for<I> S, weakly_increamentable O,
        copy_constructible F, class Proj = identity>
requires indirectly_writable<O, indirect_result_t<F&, projected<I, Proj>>>
constexpr ranges::unary_transform_result<I, O>
    ranges::transform(I first1, S last1, O result, F op, Proj proj = {});
template<input_range R, weakly_increamentable O, copy_constructible F,
        class Proj = identity>
requires indirectly_writable<O, indirect_result_t<F&, projected<iterator_t<R>, Proj>>>
constexpr ranges::unary_transform_result<borrowed_iterator_t<R>, O>
    ranges::transform(R&& r, O result, F op, Proj proj = {});
template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
        weakly_increamentable O, copy_constructible F, class Proj1 = identity,
        class Proj2 = identity>
requires indirectly_writable<O, indirect_result_t<F&, projected<I1, Proj1>,
        projected<I2, Proj2>>>
constexpr ranges::binary_transform_result<I1, I2, O>
    ranges::transform(I1 first1, S1 last1, I2 first2, S2 last2, O result,
                      F binary_op, Proj1 proj1 = {}, Proj2 proj2 = {});
template<input_range R1, input_range R2, weakly_increamentable O,
        copy_constructible F, class Proj1 = identity, class Proj2 = identity>
requires indirectly_writable<O, indirect_result_t<F&, projected<iterator_t<R1>, Proj1>,
        projected<iterator_t<R2>, Proj2>>>
constexpr ranges::binary_transform_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>, O>
    ranges::transform(R1&& r1, R2&& r2, O result,
                      F binary_op, Proj1 proj1 = {}, Proj2 proj2 = {});

```

Let:

- $last2$ be $first2 + (last1 - first1)$ for the overloads with parameter $first2$ but no parameter $last2$;
- N be $last1 - first1$ for unary transforms, or $\min(last1 - first1, last2 - first2)$ for binary transforms;
- E be
 - $op(*(first1 + (i - result)))$ for unary transforms defined in namespace `std`;
 - $binary\_op(*(first1 + (i - result)), *(first2 + (i - result)))$ for binary transforms defined in namespace `std`;
 - $invoke(op, invoke(proj, *(first1 + (i - result))))$ for unary transforms defined in namespace `ranges`;
 - $invoke(binary\_op, invoke(proj1, *(first1 + (i - result))), invoke(proj2, *(first2 + (i - result))))$ for binary transforms defined in namespace `ranges`.

Preconditions: `op` and `binary_op` do not invalidate iterators or subranges, nor modify elements in the ranges

- $[first1, first1 + N]$,
- $[first2, first2 + N]$, and

— `[result, result + N]`.²¹⁷

Effects: Assigns through every iterator `i` in the range `[result, result + N)` a new corresponding value equal to `E`.

Returns:

- `result + N` for the overloads defined in namespace `std`.
- `{first1 + N, result + N}` for unary transforms defined in namespace `ranges`.
- `{first1 + N, first2 + N, result + N}` for binary transforms defined in namespace `ranges`.

Complexity: Exactly `N` applications of `op` or `binary_op`, and any projections. This requirement also applies to the overload with an `ExecutionPolicy`.

Remarks: `result` may be equal to `first1` or `first2`.

27.7.5 Replace

[alg.replace]

```
template<class ForwardIterator, class T>
constexpr void replace(ForwardIterator first, ForwardIterator last,
                      const T& old_value, const T& new_value);
template<class ExecutionPolicy, class ForwardIterator, class T>
void replace(ExecutionPolicy&& exec,
            ForwardIterator first, ForwardIterator last,
            const T& old_value, const T& new_value);

template<class ForwardIterator, class Predicate, class T>
constexpr void replace_if(ForwardIterator first, ForwardIterator last,
                        Predicate pred, const T& new_value);
template<class ExecutionPolicy, class ForwardIterator, class Predicate, class T>
void replace_if(ExecutionPolicy&& exec,
                ForwardIterator first, ForwardIterator last,
                Predicate pred, const T& new_value);

template<input_iterator I, sentinel_for<I> S, class T1, class T2, class Proj = identity>
requires indirectly_writable<I, const T2&> &&
indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T1*>
constexpr I
ranges::replace(I first, S last, const T1& old_value, const T2& new_value, Proj proj = {});
template<input_range R, class T1, class T2, class Proj = identity>
requires indirectly_writable<iterator_t<R>, const T2&> &&
indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T1*>
constexpr borrowed_iterator_t<R>
ranges::replace(R&& r, const T1& old_value, const T2& new_value, Proj proj = {});
template<input_iterator I, sentinel_for<I> S, class T, class Proj = identity,
        indirect_unary_predicate<projected<I, Proj>> Pred>
requires indirectly_writable<I, const T&>
constexpr I ranges::replace_if(I first, S last, Pred pred, const T& new_value, Proj proj = {});
template<input_range R, class T, class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
requires indirectly_writable<iterator_t<R>, const T&>
constexpr borrowed_iterator_t<R>
ranges::replace_if(R&& r, Pred pred, const T& new_value, Proj proj = {});
```

Let `E` be

- `bool(*i == old_value)` for `replace`;
- `bool(pred(*i))` for `replace_if`;
- `bool(invoke(proj, *i) == old_value)` for `ranges::replace`;
- `bool(invoke(pred, invoke(proj, *i)))` for `ranges::replace_if`.

²¹⁷) The use of fully closed ranges is intentional.

Mandates: `new_value` is writable (25.3.1) to `first`.

Effects: Substitutes elements referred by the iterator `i` in the range `[first,last)` with `new_value`, when `E` is true.

Returns: `last` for the overloads in namespace `ranges`.

Complexity: Exactly `last - first` applications of the corresponding predicate and any projection.

```
template<class InputIterator, class OutputIterator, class T>
constexpr OutputIterator
replace_copy(InputIterator first, InputIterator last,
             OutputIterator result,
             const T& old_value, const T& new_value);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T>
ForwardIterator2
replace_copy(ExecutionPolicy&& exec,
             ForwardIterator1 first, ForwardIterator1 last,
             ForwardIterator2 result,
             const T& old_value, const T& new_value);

template<class InputIterator, class OutputIterator, class Predicate, class T>
constexpr OutputIterator
replace_copy_if(InputIterator first, InputIterator last,
                OutputIterator result,
                Predicate pred, const T& new_value);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class Predicate, class T>
ForwardIterator2
replace_copy_if(ExecutionPolicy&& exec,
                ForwardIterator1 first, ForwardIterator1 last,
                ForwardIterator2 result,
                Predicate pred, const T& new_value);

template<input_iterator I, sentinel_for<I> S, class T1, class T2, output_iterator<const T2&> O,
         class Proj = identity>
requires indirectly_copyable<I, O> &&
         indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T1*>
constexpr ranges::replace_copy_result<I, O>
ranges::replace_copy(I first, S last, O result, const T1& old_value, const T2& new_value,
                    Proj proj = {});
template<input_range R, class T1, class T2, output_iterator<const T2&> O,
         class Proj = identity>
requires indirectly_copyable<iterator_t<R>, O> &&
         indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T1*>
constexpr ranges::replace_copy_result<borrowed_iterator_t<R>, O>
ranges::replace_copy(R&& r, O result, const T1& old_value, const T2& new_value,
                    Proj proj = {});

template<input_iterator I, sentinel_for<I> S, class T, output_iterator<const T&> O,
         class Proj = identity, indirect_unary_predicate<projected<I, Proj>> Pred>
requires indirectly_copyable<I, O>
constexpr ranges::replace_copy_if_result<I, O>
ranges::replace_copy_if(I first, S last, O result, Pred pred, const T& new_value,
                       Proj proj = {});
template<input_range R, class T, output_iterator<const T&> O, class Proj = identity,
         indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
requires indirectly_copyable<iterator_t<R>, O>
constexpr ranges::replace_copy_if_result<borrowed_iterator_t<R>, O>
ranges::replace_copy_if(R&& r, O result, Pred pred, const T& new_value,
                       Proj proj = {});
```

Let `E` be

- `bool(*(first + (i - result)) == old_value)` for `replace_copy`;
- `bool(pred(*(first + (i - result))))` for `replace_copy_if`;

- `bool(invoker(proj, *(first + (i - result))) == old_value)` for `ranges::replace_copy`;
- `bool(invoker(pred, invoker(proj, *(first + (i - result))))` for `ranges::replace_copy_if`.

Mandates: The results of the expressions `*first` and `new_value` are writable (25.3.1) to `result`.

Preconditions: The ranges `[first, last)` and `[result, result + (last - first))` do not overlap.

Effects: Assigns through every iterator `i` in the range `[result, result + (last - first))` a new corresponding value

- `new_value` if `E` is true or
- `*(first + (i - result))` otherwise.

Returns:

- `result + (last - first)` for the overloads in namespace `std`.
- `{last, result + (last - first)}` for the overloads in namespace `ranges`.

Complexity: Exactly `last - first` applications of the corresponding predicate and any projection.

27.7.6 Fill

[alg.fill]

```
template<class ForwardIterator, class T>
constexpr void fill(ForwardIterator first, ForwardIterator last, const T& value);
template<class ExecutionPolicy, class ForwardIterator, class T>
void fill(ExecutionPolicy&& exec,
          ForwardIterator first, ForwardIterator last, const T& value);

template<class OutputIterator, class Size, class T>
constexpr OutputIterator fill_n(OutputIterator first, Size n, const T& value);
template<class ExecutionPolicy, class ForwardIterator, class Size, class T>
ForwardIterator fill_n(ExecutionPolicy&& exec,
                      ForwardIterator first, Size n, const T& value);

template<class T, output_iterator<const T&> 0, sentinel_for<0> S>
constexpr 0 ranges::fill(0 first, S last, const T& value);
template<class T, output_range<const T&> R>
constexpr borrowed_iterator_t<R> ranges::fill(R&& r, const T& value);
template<class T, output_iterator<const T&> 0>
constexpr 0 ranges::fill_n(0 first, iter_difference_t<0> n, const T& value);
```

Let N be $\max(0, n)$ for the `fill_n` algorithms, and `last - first` for the `fill` algorithms.

Mandates: The expression `value` is writable (25.3.1) to the output iterator. The type `Size` is convertible to an integral type (7.3.9, 11.4.8).

Effects: Assigns `value` through all the iterators in the range `[first, first + N)`.

Returns: `first + N`.

Complexity: Exactly N assignments.

27.7.7 Generate

[alg.generate]

```
template<class ForwardIterator, class Generator>
constexpr void generate(ForwardIterator first, ForwardIterator last,
                       Generator gen);
template<class ExecutionPolicy, class ForwardIterator, class Generator>
void generate(ExecutionPolicy&& exec,
             ForwardIterator first, ForwardIterator last,
             Generator gen);

template<class OutputIterator, class Size, class Generator>
constexpr OutputIterator generate_n(OutputIterator first, Size n, Generator gen);
template<class ExecutionPolicy, class ForwardIterator, class Size, class Generator>
ForwardIterator generate_n(ExecutionPolicy&& exec,
                          ForwardIterator first, Size n, Generator gen);
```

```

template<input_or_output_iterator O, sentinel_for<O> S, copy_constructible F>
    requires invocable<F&& && indirectly_writable<O, invoke_result_t<F&&>>
    constexpr O ranges::generate(O first, S last, F gen);
template<class R, copy_constructible F>
    requires invocable<F&& && output_range<R, invoke_result_t<F&&>>
    constexpr borrowed_iterator_t<R> ranges::generate(R&& r, F gen);
template<input_or_output_iterator O, copy_constructible F>
    requires invocable<F&& && indirectly_writable<O, invoke_result_t<F&&>>
    constexpr O ranges::generate_n(O first, iter_difference_t<O> n, F gen);

```

Let N be $\max(0, n)$ for the `generate_n` algorithms, and $\text{last} - \text{first}$ for the `generate` algorithms.

Mandates: Size is convertible to an integral type (7.3.9, 11.4.8).

Effects: Assigns the result of successive evaluations of `gen()` through each iterator in the range $[\text{first}, \text{first} + N)$.

Returns: $\text{first} + N$.

Complexity: Exactly N evaluations of `gen()` and assignments.

27.7.8 Remove

[alg.remove]

```

template<class ForwardIterator, class T>
    constexpr ForwardIterator remove(ForwardIterator first, ForwardIterator last,
                                    const T& value);
template<class ExecutionPolicy, class ForwardIterator, class T>
    ForwardIterator remove(ExecutionPolicy&& exec,
                          ForwardIterator first, ForwardIterator last,
                          const T& value);

template<class ForwardIterator, class Predicate>
    constexpr ForwardIterator remove_if(ForwardIterator first, ForwardIterator last,
                                       Predicate pred);
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
    ForwardIterator remove_if(ExecutionPolicy&& exec,
                             ForwardIterator first, ForwardIterator last,
                             Predicate pred);

template<permutable I, sentinel_for<I> S, class T, class Proj = identity>
    requires indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T*>
    constexpr subrange<I> ranges::remove(I first, S last, const T& value, Proj proj = {});
template<forward_range R, class T, class Proj = identity>
    requires permutable<iterator_t<R>> &&
           indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T*>
    constexpr borrowed_subrange_t<R>
        ranges::remove(R&& r, const T& value, Proj proj = {});
template<permutable I, sentinel_for<I> S, class Proj = identity,
        indirect_unary_predicate<projected<I, Proj>> Pred>
    constexpr subrange<I> ranges::remove_if(I first, S last, Pred pred, Proj proj = {});
template<forward_range R, class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
    requires permutable<iterator_t<R>>
    constexpr borrowed_subrange_t<R>
        ranges::remove_if(R&& r, Pred pred, Proj proj = {});

```

Let E be

- `bool(*i == value)` for `remove`;
- `bool(pred(*i))` for `remove_if`;
- `bool(invoker(proj, *i) == value)` for `ranges::remove`;
- `bool(invoker(pred, invoker(proj, *i)))` for `ranges::remove_if`.

Preconditions: For the algorithms in namespace `std`, the type of `*first` meets the *Cpp17MoveAssignable* requirements (Table 33).

Effects: Eliminates all the elements referred to by iterator *i* in the range $[first, last)$ for which *E* holds.

Returns: Let *j* be the end of the resulting range. Returns:

- *j* for the overloads in namespace `std`.
- $\{j, last\}$ for the overloads in namespace `ranges`.

Complexity: Exactly `last - first` applications of the corresponding predicate and any projection.

Remarks: Stable (16.4.6.8).

NOTE 1 Each element in the range $[ret, last)$, where `ret` is the returned value, has a valid but unspecified state, because the algorithms can eliminate elements by moving from elements that were originally in that range.

```
template<class InputIterator, class OutputIterator, class T>
constexpr OutputIterator
    remove_copy(InputIterator first, InputIterator last,
                OutputIterator result, const T& value);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class T>
ForwardIterator2
    remove_copy(ExecutionPolicy&& exec,
                ForwardIterator1 first, ForwardIterator1 last,
                ForwardIterator2 result, const T& value);

template<class InputIterator, class OutputIterator, class Predicate>
constexpr OutputIterator
    remove_copy_if(InputIterator first, InputIterator last,
                   OutputIterator result, Predicate pred);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class Predicate>
ForwardIterator2
    remove_copy_if(ExecutionPolicy&& exec,
                   ForwardIterator1 first, ForwardIterator1 last,
                   ForwardIterator2 result, Predicate pred);

template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, class T,
        class Proj = identity>
requires indirectly_copyable<I, O> &&
    indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T*>
constexpr ranges::remove_copy_result<I, O>
    ranges::remove_copy(I first, S last, O result, const T& value, Proj proj = {});
template<input_range R, weakly_incrementable O, class T, class Proj = identity>
requires indirectly_copyable<iterator_t<R>, O> &&
    indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T*>
constexpr ranges::remove_copy_result<borrowed_iterator_t<R>, O>
    ranges::remove_copy(R&& r, O result, const T& value, Proj proj = {});
template<input_iterator I, sentinel_for<I> S, weakly_incrementable O,
        class Proj = identity, indirect_unary_predicate<projected<I, Proj>> Pred>
requires indirectly_copyable<I, O>
constexpr ranges::remove_copy_if_result<I, O>
    ranges::remove_copy_if(I first, S last, O result, Pred pred, Proj proj = {});
template<input_range R, weakly_incrementable O, class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
requires indirectly_copyable<iterator_t<R>, O>
constexpr ranges::remove_copy_if_result<borrowed_iterator_t<R>, O>
    ranges::remove_copy_if(R&& r, O result, Pred pred, Proj proj = {});
```

Let *E* be

- `bool(*i == value)` for `remove_copy`;
- `bool(pred(*i))` for `remove_copy_if`;
- `bool(invoker(proj, *i) == value)` for `ranges::remove_copy`;
- `bool(invoker(pred, invoker(proj, *i)))` for `ranges::remove_copy_if`.

Let N be the number of elements in $[\text{first}, \text{last})$ for which E is false.

Mandates: *first is writable (25.3.1) to result.

Preconditions: The ranges $[\text{first}, \text{last})$ and $[\text{result}, \text{result} + (\text{last} - \text{first}))$ do not overlap.

NOTE 2 For the overloads with an `ExecutionPolicy`, a performance cost is possible if `iterator_traits<ForwardIterator1>::value_type` does not meet the *Cpp17MoveConstructible* (Table 31) requirements.

Effects: Copies all the elements referred to by the iterator i in the range $[\text{first}, \text{last})$ for which E is false.

Returns:

- $\text{result} + N$, for the algorithms in namespace `std`.
- $\{\text{last}, \text{result} + N\}$, for the algorithms in namespace `ranges`.

Complexity: Exactly $\text{last} - \text{first}$ applications of the corresponding predicate and any projection.

Remarks: Stable (16.4.6.8).

27.7.9 Unique

[alg.unique]

```
template<class ForwardIterator>
constexpr ForwardIterator unique(ForwardIterator first, ForwardIterator last);
template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator unique(ExecutionPolicy&& exec,
                      ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class BinaryPredicate>
constexpr ForwardIterator unique(ForwardIterator first, ForwardIterator last,
                               BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator, class BinaryPredicate>
ForwardIterator unique(ExecutionPolicy&& exec,
                      ForwardIterator first, ForwardIterator last,
                      BinaryPredicate pred);

template<permutable I, sentinel_for<I> S, class Proj = identity,
        indirect_equivalence_relation<projected<I, Proj>> C = ranges::equal_to>
constexpr subrange<I> ranges::unique(I first, S last, C comp = {}, Proj proj = {});
template<forward_range R, class Proj = identity,
        indirect_equivalence_relation<projected<iterator_t<R>, Proj>> C = ranges::equal_to>
requires permutable<iterator_t<R>>
constexpr borrowed_subrange_t<R>
ranges::unique(R&& r, C comp = {}, Proj proj = {});
```

Let `pred` be `equal_to{}` for the overloads with no parameter `pred`, and let E be

- `bool(pred(*(i - 1), *i))` for the overloads in namespace `std`;
- `bool(invoker(comp, invoker(proj, *(i - 1)), invoker(proj, *i)))` for the overloads in namespace `ranges`.

Preconditions: For the overloads in namespace `std`, `pred` is an equivalence relation and the type of *first meets the *Cpp17MoveAssignable* requirements (Table 33).

Effects: For a nonempty range, eliminates all but the first element from every consecutive group of equivalent elements referred to by the iterator i in the range $[\text{first} + 1, \text{last})$ for which E is true.

Returns: Let j be the end of the resulting range. Returns:

- j for the overloads in namespace `std`.
- $\{j, \text{last}\}$ for the overloads in namespace `ranges`.

Complexity: For nonempty ranges, exactly $(\text{last} - \text{first}) - 1$ applications of the corresponding predicate and no more than twice as many applications of any projection.

```
template<class InputIterator, class OutputIterator>
constexpr OutputIterator
unique_copy(InputIterator first, InputIterator last,
           OutputIterator result);
```

```

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
    unique_copy(ExecutionPolicy&& exec,
                ForwardIterator1 first, ForwardIterator1 last,
                ForwardIterator2 result);

template<class InputIterator, class OutputIterator,
         class BinaryPredicate>
constexpr OutputIterator
    unique_copy(InputIterator first, InputIterator last,
                OutputIterator result, BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
ForwardIterator2
    unique_copy(ExecutionPolicy&& exec,
                ForwardIterator1 first, ForwardIterator1 last,
                ForwardIterator2 result, BinaryPredicate pred);

template<input_iterator I, sentinel_for<I> S, weakly_increamentable O, class Proj = identity,
         indirect_equivalence_relation<projected<I, Proj>> C = ranges::equal_to>
requires indirectly_copyable<I, O> &&
    (forward_iterator<I> ||
     (input_iterator<O> && same_as<iter_value_t<I>, iter_value_t<O>>) ||
     indirectly_copyable_storable<I, O>)
constexpr ranges::unique_copy_result<I, O>
    ranges::unique_copy(I first, S last, O result, C comp = {}, Proj proj = {});
template<input_range R, weakly_increamentable O, class Proj = identity,
         indirect_equivalence_relation<projected<iterator_t<R>, Proj>> C = ranges::equal_to>
requires indirectly_copyable<iterator_t<R>, O> &&
    (forward_iterator<iterator_t<R>> ||
     (input_iterator<O> && same_as<range_value_t<R>, iter_value_t<O>>) ||
     indirectly_copyable_storable<iterator_t<R>, O>)
constexpr ranges::unique_copy_result<borrowed_iterator_t<R>, O>
    ranges::unique_copy(R&& r, O result, C comp = {}, Proj proj = {});

```

Let `pred` be `equal_to{}` for the overloads in namespace `std` with no parameter `pred`, and let E be

- `bool(pred(*i, *(i - 1)))` for the overloads in namespace `std`;
- `bool(invoker(comp, invoker(proj, *i), invoker(proj, *(i - 1))))` for the overloads in namespace `ranges`.

Mandates: `*first` is writable (25.3.1) to `result`.

Preconditions:

- The ranges `[first, last)` and `[result, result+(last-first))` do not overlap.
- For the overloads in namespace `std`:
 - The comparison function is an equivalence relation.

For the overloads with no `ExecutionPolicy`, let T be the value type of `InputIterator`. If `InputIterator` models `forward_iterator` (25.3.4.11), then there are no additional requirements for T . Otherwise, if `OutputIterator` meets the *Cpp17ForwardIterator* requirements and its value type is the same as T , then T meets the *Cpp17CopyAssignable* (Table 34) requirements. Otherwise, T meets both the *Cpp17CopyConstructible* (Table 32) and *Cpp17CopyAssignable* requirements.

NOTE For the overloads with an `ExecutionPolicy`, a performance cost is possible if the value type of `ForwardIterator1` does not meet both the *Cpp17CopyConstructible* and *Cpp17CopyAssignable* requirements.

Effects: Copies only the first element from every consecutive group of equal elements referred to by the iterator i in the range `[first, last)` for which E holds.

Returns:

- `result + N` for the overloads in namespace `std`.

— {last, result + N} for the overloads in namespace ranges.

Complexity: Exactly last - first - 1 applications of the corresponding predicate and no more than twice as many applications of any projection.

27.7.10 Reverse

[alg.reverse]

```
template<class BidirectionalIterator>
constexpr void reverse(BidirectionalIterator first, BidirectionalIterator last);
template<class ExecutionPolicy, class BidirectionalIterator>
void reverse(ExecutionPolicy&& exec,
             BidirectionalIterator first, BidirectionalIterator last);
```

```
template<bidirectional_iterator I, sentinel_for<I> S>
requires permutable<I>
constexpr I ranges::reverse(I first, S last);
template<bidirectional_range R>
requires permutable<iterator_t<R>>
constexpr borrowed_iterator_t<R> ranges::reverse(R&& r);
```

Preconditions: For the overloads in namespace std, BidirectionalIterator meets the Cpp17ValueSwappable requirements (16.4.4.3).

Effects: For each non-negative integer $i < (\text{last} - \text{first}) / 2$, applies std::iter_swap, or ranges::iter_swap for the overloads in namespace ranges, to all pairs of iterators first + i, (last - i) - 1.

Returns: last for the overloads in namespace ranges.

Complexity: Exactly (last - first)/2 swaps.

```
template<class BidirectionalIterator, class OutputIterator>
constexpr OutputIterator
reverse_copy(BidirectionalIterator first, BidirectionalIterator last,
            OutputIterator result);
template<class ExecutionPolicy, class BidirectionalIterator, class ForwardIterator>
ForwardIterator
reverse_copy(ExecutionPolicy&& exec,
             BidirectionalIterator first, BidirectionalIterator last,
             ForwardIterator result);
```

```
template<bidirectional_iterator I, sentinel_for<I> S, weakly_incremtable O>
requires indirectly_copyable<I, O>
constexpr ranges::reverse_copy_result<I, O>
ranges::reverse_copy(I first, S last, O result);
template<bidirectional_range R, weakly_incremtable O>
requires indirectly_copyable<iterator_t<R>, O>
constexpr ranges::reverse_copy_result<borrowed_iterator_t<R>, O>
ranges::reverse_copy(R&& r, O result);
```

Let N be last - first.

Preconditions: The ranges [first, last) and [result, result + N) do not overlap.

Effects: Copies the range [first, last) to the range [result, result + N) such that for every non-negative integer $i < N$ the following assignment takes place: $*(\text{result} + N - 1 - i) = *(\text{first} + i)$.

Returns:

— result + N for the overloads in namespace std.

— {last, result + N} for the overloads in namespace ranges.

Complexity: Exactly N assignments.

27.7.11 Rotate

[alg.rotate]

```
template<class ForwardIterator>
constexpr ForwardIterator
rotate(ForwardIterator first, ForwardIterator middle, ForwardIterator last);
template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
rotate(ExecutionPolicy&& exec,
       ForwardIterator first, ForwardIterator middle, ForwardIterator last);
```

```
template<permutable I, sentinel_for<I> S>
constexpr subrange<I> ranges::rotate(I first, I middle, S last);
```

Preconditions: $[first, middle)$ and $[middle, last)$ are valid ranges. For the overloads in namespace `std`, `ForwardIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3), and the type of `*first` meets the *Cpp17MoveConstructible* (Table 31) and *Cpp17MoveAssignable* (Table 33) requirements.

Effects: For each non-negative integer $i < (last - first)$, places the element from the position $first + i$ into position $first + (i + (last - middle)) \% (last - first)$.

NOTE This is a left rotate.

Returns:

- $first + (last - middle)$ for the overloads in namespace `std`.
- $\{first + (last - middle), last\}$ for the overload in namespace `ranges`.

Complexity: At most $last - first$ swaps.

```
template<forward_range R>
requires permutable<iterator_t<R>>
constexpr borrowed_subrange_t<R> ranges::rotate(R&& r, iterator_t<R> middle);
```

Effects: Equivalent to: `return ranges::rotate(ranges::begin(r), middle, ranges::end(r));`

```
template<class ForwardIterator, class OutputIterator>
constexpr OutputIterator
rotate_copy(ForwardIterator first, ForwardIterator middle, ForwardIterator last,
            OutputIterator result);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
rotate_copy(ExecutionPolicy&& exec,
            ForwardIterator1 first, ForwardIterator1 middle, ForwardIterator1 last,
            ForwardIterator2 result);
```

```
template<forward_iterator I, sentinel_for<I> S, weakly_incrementable O>
requires indirectly_copyable<I, O>
constexpr ranges::rotate_copy_result<I, O>
ranges::rotate_copy(I first, I middle, S last, O result);
```

Let N be $last - first$.

Preconditions: $[first, middle)$ and $[middle, last)$ are valid ranges. The ranges $[first, last)$ and $[result, result + N)$ do not overlap.

Effects: Copies the range $[first, last)$ to the range $[result, result + N)$ such that for each non-negative integer $i < N$ the following assignment takes place: $*(result + i) = *(first + (i + (middle - first)) \% N)$.

Returns:

- $result + N$ for the overloads in namespace `std`.
- $\{last, result + N\}$ for the overload in namespace `ranges`.

Complexity: Exactly N assignments.

```
template<forward_range R, weakly_incrementable O>
requires indirectly_copyable<iterator_t<R>, O>
constexpr ranges::rotate_copy_result<borrowed_iterator_t<R>, O>
```

```
ranges::rotate_copy(R&& r, iterator_t<R> middle, O result);
```

Effects: Equivalent to:

```
return ranges::rotate_copy(ranges::begin(r), middle, ranges::end(r), std::move(result));
```

27.7.12 Sample

[alg.random.sample]

```
template<class PopulationIterator, class SampleIterator,
        class Distance, class UniformRandomBitGenerator>
SampleIterator sample(PopulationIterator first, PopulationIterator last,
                    SampleIterator out, Distance n,
                    UniformRandomBitGenerator&& g);

template<input_iterator I, sentinel_for<I> S, weakly_incremtable O, class Gen>
requires (forward_iterator<I> || random_access_iterator<O>) &&
    indirectly_copyable<I, O> &&
    uniform_random_bit_generator<remove_reference_t<Gen>>
O ranges::sample(I first, S last, O out, iter_difference_t<I> n, Gen&& g);
template<input_range R, weakly_incremtable O, class Gen>
requires (forward_range<R> || random_access_iterator<O>) &&
    indirectly_copyable<iterator_t<R>, O> &&
    uniform_random_bit_generator<remove_reference_t<Gen>>
O ranges::sample(R&& r, O out, range_difference_t<R> n, Gen&& g);
```

Mandates: For the overload in namespace `std`, `Distance` is an integer type and `*first` is writable (25.3.1) to `out`.

Preconditions: `out` is not in the range `[first, last)`. For the overload in namespace `std`:

- `PopulationIterator` meets the *Cpp17InputIterator* requirements (25.3.5.3).
- `SampleIterator` meets the *Cpp17OutputIterator* requirements (25.3.5.4).
- `SampleIterator` meets the *Cpp17RandomAccessIterator* requirements (25.3.5.7) unless `PopulationIterator` models *forward_iterator* (25.3.4.11).
- `remove_reference_t<UniformRandomBitGenerator>` meets the requirements of a uniform random bit generator type (28.5.3.3).

Effects: Copies `min(last - first, n)` elements (the *sample*) from `[first, last)` (the *population*) to `out` such that each possible sample has equal probability of appearance.

NOTE Algorithms that obtain such effects include *selection sampling* and *reservoir sampling*.

Returns: The end of the resulting sample range.

Complexity: $\mathcal{O}(\text{last} - \text{first})$.

Remarks:

- For the overload in namespace `std`, stable if and only if `PopulationIterator` models *forward_iterator*. For the first overload in namespace `ranges`, stable if and only if `I` models *forward_iterator*.
- To the extent that the implementation of this function makes use of random numbers, the object `g` serves as the implementation's source of randomness.

27.7.13 Shuffle

[alg.random.shuffle]

```
template<class RandomAccessIterator, class UniformRandomBitGenerator>
void shuffle(RandomAccessIterator first,
            RandomAccessIterator last,
            UniformRandomBitGenerator&& g);

template<random_access_iterator I, sentinel_for<I> S, class Gen>
requires permutable<I> &&
    uniform_random_bit_generator<remove_reference_t<Gen>>
I ranges::shuffle(I first, S last, Gen&& g);
```

```
template<random_access_range R, class Gen>
requires permutable<iterator_t<R>> &&
    uniform_random_bit_generator<remove_reference_t<Gen>>
borrowed_iterator_t<R> ranges::shuffle(R&& r, Gen&& g);
```

Preconditions: For the overload in namespace `std`:

- `RandomAccessIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3).
- The type `remove_reference_t<UniformRandomBitGenerator>` meets the uniform random bit generator (28.5.3.3) requirements.

Effects: Permutes the elements in the range `[first, last)` such that each possible permutation of those elements has equal probability of appearance.

Returns: `last` for the overloads in namespace `ranges`.

Complexity: Exactly $(last - first) - 1$ swaps.

Remarks: To the extent that the implementation of this function makes use of random numbers, the object referenced by `g` shall serve as the implementation's source of randomness.

27.7.14 Shift

[alg.shift]

```
template<class ForwardIterator>
constexpr ForwardIterator
    shift_left(ForwardIterator first, ForwardIterator last,
               typename iterator_traits<ForwardIterator>::difference_type n);
template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
    shift_left(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
               typename iterator_traits<ForwardIterator>::difference_type n);

template<permutable I, sentinel_for<I> S>
constexpr subrange<I> ranges::shift_left(I first, S last, iter_difference_t<I> n);
template<forward_range R>
requires permutable<iterator_t<R>>
constexpr borrowed_subrange_t<R> ranges::shift_left(R&& r, range_difference_t<R> n)
```

Preconditions: $n \geq 0$ is true. For the overloads in namespace `std`, the type of `*first` meets the *Cpp17MoveAssignable* requirements.

Effects: If $n == 0$ or $n \geq last - first$, does nothing. Otherwise, moves the element from position `first + n + i` into position `first + i` for each non-negative integer $i < (last - first) - n$. For the overloads without an `ExecutionPolicy` template parameter, does so in order starting from $i = 0$ and proceeding to $i = (last - first) - n - 1$.

Returns: Let `NEW_LAST` be `first + (last - first - n)` if $n < last - first$, otherwise `first`.

- `NEW_LAST` for the overloads in namespace `std`.
- `{first, NEW_LAST}` for the overloads in namespace `ranges`.

Complexity: At most $(last - first) - n$ assignments.

```
template<class ForwardIterator>
constexpr ForwardIterator
    shift_right(ForwardIterator first, ForwardIterator last,
                typename iterator_traits<ForwardIterator>::difference_type n);
template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
    shift_right(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
                typename iterator_traits<ForwardIterator>::difference_type n);

template<permutable I, sentinel_for<I> S>
constexpr subrange<I> ranges::shift_right(I first, S last, iter_difference_t<I> n);
template<forward_range R>
requires permutable<iterator_t<R>>
```

```
constexpr borrowed_subrange_t<R> ranges::shift_right(R&& r, range_difference_t<R> n);
```

Preconditions: $n \geq 0$ is true. For the overloads in namespace `std`, the type of `*first` meets the *Cpp17MoveAssignable* requirements, and `ForwardIterator` meets the *Cpp17BidirectionalIterator* requirements (25.3.5.6) or the *Cpp17ValueSwappable* requirements.

Effects: If $n == 0$ or $n \geq \text{last} - \text{first}$, does nothing. Otherwise, moves the element from position $\text{first} + i$ into position $\text{first} + n + i$ for each non-negative integer $i < (\text{last} - \text{first}) - n$. Does so in order starting from $i = (\text{last} - \text{first}) - n - 1$ and proceeding to $i = 0$ if

- for the overload in namespace `std` without an `ExecutionPolicy` template parameter, `ForwardIterator` meets the *Cpp17BidirectionalIterator* requirements,
- for the overloads in namespace `ranges`, `I` models `bidirectional_iterator`.

Returns: Let `NEW_FIRST` be $\text{first} + n$ if $n < \text{last} - \text{first}$, otherwise `last`.

- `NEW_FIRST` for the overloads in namespace `std`.
- $\{\text{NEW\_FIRST}, \text{last}\}$ for the overloads in namespace `ranges`.

Complexity: At most $(\text{last} - \text{first}) - n$ assignments or swaps.

27.8 Sorting and related operations

[alg.sorting]

27.8.1 General

[alg.sorting.general]

The operations in 27.8 defined directly in namespace `std` have two versions: one that takes a function object of type `Compare` and one that uses `operator<`.

`Compare` is a function object type (22.10) that meets the requirements for a template parameter named `BinaryPredicate` (27.2). The return value of the function call operation applied to an object of type `Compare`, when converted to `bool`, yields `true` if the first argument of the call is less than the second, and `false` otherwise. `Compare comp` is used throughout for algorithms assuming an ordering relation.

For all algorithms that take `Compare`, there is a version that uses `operator<` instead. That is, `comp(*i, *j) != false` defaults to `*i < *j != false`. For algorithms other than those described in 27.8.4, `comp` shall induce a strict weak ordering on the values.

The term *strict* refers to the requirement of an irreflexive relation ($!\text{comp}(x, x)$ for all x), and the term *weak* to requirements that are not as strong as those for a total ordering, but stronger than those for a partial ordering. If we define `equiv(a, b)` as $!\text{comp}(a, b) \ \&\& \ !\text{comp}(b, a)$, then the requirements are that `comp` and `equiv` both be transitive relations:

- `comp(a, b) &\& comp(b, c)` implies `comp(a, c)`
- `equiv(a, b) &\& equiv(b, c)` implies `equiv(a, c)`

NOTE Under these conditions, it can be shown that

- `equiv` is an equivalence relation,
- `comp` induces a well-defined relation on the equivalence classes determined by `equiv`, and
- the induced relation is a strict total ordering.

A sequence is *sorted with respect to a comp and proj* for a comparator and projection `comp` and `proj` if for every iterator `i` pointing to the sequence and every non-negative integer n such that $i + n$ is a valid iterator pointing to an element of the sequence,

```
bool(invoke(comp, invoke(proj, *(i + n)), invoke(proj, *i)))
```

is false.

A sequence is *sorted with respect to a comparator comp* for a comparator `comp` if it is sorted with respect to `comp` and `identity{}` (the identity projection).

A sequence $[\text{start}, \text{finish})$ is *partitioned with respect to an expression f(e)* if there exists an integer n such that for all $0 \leq i < (\text{finish} - \text{start})$, $f(\text{start} + i)$ is true if and only if $i < n$.

In the descriptions of the functions that deal with ordering relationships we frequently use a notion of equivalence to describe concepts such as stability. The equivalence to which we refer is not necessarily an `operator==`, but an equivalence relation induced by the strict weak ordering. That is, two elements `a` and `b` are considered equivalent if and only if $!(a < b) \ \&\& \ !(b < a)$.

27.8.2 Sorting

[alg.sort]

27.8.2.1 sort

[sort]

```

template<class RandomAccessIterator>
constexpr void sort(RandomAccessIterator first, RandomAccessIterator last);
template<class ExecutionPolicy, class RandomAccessIterator>
void sort(ExecutionPolicy&& exec,
          RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void sort(RandomAccessIterator first, RandomAccessIterator last,
                    Compare comp);
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void sort(ExecutionPolicy&& exec,
          RandomAccessIterator first, RandomAccessIterator last,
          Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
        class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
    ranges::sort(I first, S last, Comp comp = {}, Proj proj = {});
template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
    ranges::sort(R&& r, Comp comp = {}, Proj proj = {});

```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

Preconditions: For the overloads in namespace `std`, `RandomAccessIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3) and the type of `*first` meets the *Cpp17MoveConstructible* (Table 31) and *Cpp17MoveAssignable* (Table 33) requirements.

Effects: Sorts the elements in the range `[first, last)` with respect to `comp` and `proj`.

Returns: `last` for the overloads in namespace `ranges`.

Complexity: Let N be `last - first`. $\mathcal{O}(N \log N)$ comparisons and projections.

27.8.2.2 stable_sort

[stable.sort]

```

template<class RandomAccessIterator>
void stable_sort(RandomAccessIterator first, RandomAccessIterator last);
template<class ExecutionPolicy, class RandomAccessIterator>
void stable_sort(ExecutionPolicy&& exec,
                RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
void stable_sort(RandomAccessIterator first, RandomAccessIterator last,
                Compare comp);
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void stable_sort(ExecutionPolicy&& exec,
                RandomAccessIterator first, RandomAccessIterator last,
                Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
        class Proj = identity>
requires sortable<I, Comp, Proj>
I ranges::stable_sort(I first, S last, Comp comp = {}, Proj proj = {});
template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
borrowed_iterator_t<R>
    ranges::stable_sort(R&& r, Comp comp = {}, Proj proj = {});

```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

Preconditions: For the overloads in namespace `std`, `RandomAccessIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3) and the type of `*first` meets the *Cpp17MoveConstructible* (Table 31) and *Cpp17MoveAssignable* (Table 33) requirements.

Effects: Sorts the elements in the range `[first, last)` with respect to `comp` and `proj`.

Returns: `last` for the overloads in namespace `ranges`.

Complexity: Let N be `last - first`. If enough extra memory is available, $N \log(N)$ comparisons. Otherwise, at most $N \log^2(N)$ comparisons. In either case, twice as many projections as the number of comparisons.

Remarks: Stable (16.4.6.8).

27.8.2.3 `partial_sort`

[partial.sort]

```
template<class RandomAccessIterator>
constexpr void partial_sort(RandomAccessIterator first,
                           RandomAccessIterator middle,
                           RandomAccessIterator last);
template<class ExecutionPolicy, class RandomAccessIterator>
void partial_sort(ExecutionPolicy&& exec,
                 RandomAccessIterator first,
                 RandomAccessIterator middle,
                 RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void partial_sort(RandomAccessIterator first,
                           RandomAccessIterator middle,
                           RandomAccessIterator last,
                           Compare comp);
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void partial_sort(ExecutionPolicy&& exec,
                 RandomAccessIterator first,
                 RandomAccessIterator middle,
                 RandomAccessIterator last,
                 Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
        class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
ranges::partial_sort(I first, I middle, S last, Comp comp = {}, Proj proj = {});
```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

Preconditions: `[first, middle)` and `[middle, last)` are valid ranges. For the overloads in namespace `std`, `RandomAccessIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3) and the type of `*first` meets the *Cpp17MoveConstructible* (Table 31) and *Cpp17MoveAssignable* (Table 33) requirements.

Effects: Places the first `middle - first` elements from the range `[first, last)` as sorted with respect to `comp` and `proj` into the range `[first, middle)`. The rest of the elements in the range `[middle, last)` are placed in an unspecified order.

Returns: `last` for the overload in namespace `ranges`.

Complexity: Approximately $(last - first) * \log(middle - first)$ comparisons, and twice as many projections.

```
template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
ranges::partial_sort(R&& r, iterator_t<R> middle, Comp comp = {}, Proj proj = {});
```

Effects: Equivalent to:

```
return ranges::partial_sort(ranges::begin(r), middle, ranges::end(r), comp, proj);
```

27.8.2.4 partial_sort_copy

[partial.sort.copy]

```

template<class InputIterator, class RandomAccessIterator>
constexpr RandomAccessIterator
    partial_sort_copy(InputIterator first, InputIterator last,
                      RandomAccessIterator result_first,
                      RandomAccessIterator result_last);

template<class ExecutionPolicy, class ForwardIterator, class RandomAccessIterator>
RandomAccessIterator
    partial_sort_copy(ExecutionPolicy&& exec,
                      ForwardIterator first, ForwardIterator last,
                      RandomAccessIterator result_first,
                      RandomAccessIterator result_last);

template<class InputIterator, class RandomAccessIterator,
         class Compare>
constexpr RandomAccessIterator
    partial_sort_copy(InputIterator first, InputIterator last,
                      RandomAccessIterator result_first,
                      RandomAccessIterator result_last,
                      Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class RandomAccessIterator,
         class Compare>
RandomAccessIterator
    partial_sort_copy(ExecutionPolicy&& exec,
                      ForwardIterator first, ForwardIterator last,
                      RandomAccessIterator result_first,
                      RandomAccessIterator result_last,
                      Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, random_access_iterator I2, sentinel_for<I2> S2,
         class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires indirectly_copyable<I1, I2> && sortable<I2, Comp, Proj2> &&
    indirect_strict_weak_order<Comp, projected<I1, Proj1>, projected<I2, Proj2>>
constexpr ranges::partial_sort_copy_result<I1, I2>
    ranges::partial_sort_copy(I1 first, S1 last, I2 result_first, S2 result_last,
                              Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, random_access_range R2, class Comp = ranges::less,
         class Proj1 = identity, class Proj2 = identity>
requires indirectly_copyable<iterator_t<R1>, iterator_t<R2>> &&
    sortable<iterator_t<R2>, Comp, Proj2> &&
    indirect_strict_weak_order<Comp, projected<iterator_t<R1>, Proj1>,
                              projected<iterator_t<R2>, Proj2>>
constexpr ranges::partial_sort_copy_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>>
    ranges::partial_sort_copy(R1&& r, R2&& result_r, Comp comp = {},
                              Proj1 proj1 = {}, Proj2 proj2 = {});

```

Let N be $\min(\text{last} - \text{first}, \text{result\_last} - \text{result\_first})$. Let comp be $\text{less}\{\}$, and proj1 and proj2 be $\text{identity}\{\}$ for the overloads with no parameters by those names.

Mandates: For the overloads in namespace `std`, the expression `*first` is writable (25.3.1) to `result_first`.

Preconditions: For the overloads in namespace `std`, `RandomAccessIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3), the type of `*result_first` meets the *Cpp17MoveConstructible* (Table 31) and *Cpp17MoveAssignable* (Table 33) requirements.

For iterators $a1$ and $b1$ in $[\text{first}, \text{last})$, and iterators $x2$ and $y2$ in $[\text{result\_first}, \text{result\_last})$, after evaluating the assignment `*y2 = *b1`, let E be the value of

```
bool(invoker(comp, invoker(proj1, *a1), invoker(proj2, *y2))).
```

Then, after evaluating the assignment `*x2 = *a1`, E is equal to

```
bool(invoker(comp, invoker(proj2, *x2), invoker(proj2, *y2))).
```

NOTE Writing a value from the input range into the output range does not affect how it is ordered by `comp` and `proj1` or `proj2`.

Effects: Places the first N elements as sorted with respect to `comp` and `proj2` into the range `[result_first, result_first + N)`.

Returns:

- `result_first + N` for the overloads in namespace `std`.
- `{last, result_first + N}` for the overloads in namespace `ranges`.

Complexity: Approximately $(last - first) * \log N$ comparisons, and twice as many projections.

27.8.2.5 `is_sorted`

[is.sorted]

```
template<class ForwardIterator>
constexpr bool is_sorted(ForwardIterator first, ForwardIterator last);

Effects: Equivalent to: return is_sorted_until(first, last) == last;

template<class ExecutionPolicy, class ForwardIterator>
bool is_sorted(ExecutionPolicy&& exec,
               ForwardIterator first, ForwardIterator last);

Effects: Equivalent to:
    return is_sorted_until(std::forward<ExecutionPolicy>(exec), first, last) == last;

template<class ForwardIterator, class Compare>
constexpr bool is_sorted(ForwardIterator first, ForwardIterator last,
                         Compare comp);

Effects: Equivalent to: return is_sorted_until(first, last, comp) == last;

template<class ExecutionPolicy, class ForwardIterator, class Compare>
bool is_sorted(ExecutionPolicy&& exec,
               ForwardIterator first, ForwardIterator last,
               Compare comp);

Effects: Equivalent to:
    return is_sorted_until(std::forward<ExecutionPolicy>(exec), first, last, comp) == last;

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr bool ranges::is_sorted(I first, S last, Comp comp = {}, Proj proj = {});

template<forward_range R, class Proj = identity,
        indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr bool ranges::is_sorted(R&& r, Comp comp = {}, Proj proj = {});

Effects: Equivalent to: return ranges::is_sorted_until(first, last, comp, proj) == last;

template<class ForwardIterator>
constexpr ForwardIterator
    is_sorted_until(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
    is_sorted_until(ExecutionPolicy&& exec,
                   ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
constexpr ForwardIterator
    is_sorted_until(ForwardIterator first, ForwardIterator last,
                   Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class Compare>
ForwardIterator
    is_sorted_until(ExecutionPolicy&& exec,
                   ForwardIterator first, ForwardIterator last,
                   Compare comp);

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::is_sorted_until(I first, S last, Comp comp = {}, Proj proj = {});
```

```
template<forward_range R, class Proj = identity,
        indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr borrowed_iterator_t<R>
ranges::is_sorted_until(R&& r, Comp comp = {}, Proj proj = {});
```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

Returns: The last iterator `i` in `[first, last]` for which the range `[first, i)` is sorted with respect to `comp` and `proj`.

Complexity: Linear.

27.8.3 Nth element

[alg.nth.element]

```
template<class RandomAccessIterator>
constexpr void nth_element(RandomAccessIterator first, RandomAccessIterator nth,
                          RandomAccessIterator last);
template<class ExecutionPolicy, class RandomAccessIterator>
void nth_element(ExecutionPolicy&& exec,
                RandomAccessIterator first, RandomAccessIterator nth,
                RandomAccessIterator last);
```

```
template<class RandomAccessIterator, class Compare>
constexpr void nth_element(RandomAccessIterator first, RandomAccessIterator nth,
                          RandomAccessIterator last, Compare comp);
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void nth_element(ExecutionPolicy&& exec,
                RandomAccessIterator first, RandomAccessIterator nth,
                RandomAccessIterator last, Compare comp);
```

```
template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
        class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
ranges::nth_element(I first, I nth, S last, Comp comp = {}, Proj proj = {});
```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

Preconditions: `[first, nth)` and `[nth, last)` are valid ranges. For the overloads in namespace `std`, `RandomAccessIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3), and the type of `*first` meets the *Cpp17MoveConstructible* (Table 31) and *Cpp17MoveAssignable* (Table 33) requirements.

Effects: After `nth_element` the element in the position pointed to by `nth` is the element that would be in that position if the whole range were sorted with respect to `comp` and `proj`, unless `nth == last`. Also for every iterator `i` in the range `[first, nth)` and every iterator `j` in the range `[nth, last)` it holds that: `bool(invoker(comp, invoker(proj, *j), invoker(proj, *i)))` is false.

Returns: `last` for the overload in namespace `ranges`.

Complexity: For the overloads with no `ExecutionPolicy`, linear on average. For the overloads with an `ExecutionPolicy`, $\mathcal{O}(N)$ applications of the predicate, and $\mathcal{O}(N \log N)$ swaps, where $N = \text{last} - \text{first}$.

```
template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
ranges::nth_element(R&& r, iterator_t<R> nth, Comp comp = {}, Proj proj = {});
```

Effects: Equivalent to:

```
return ranges::nth_element(ranges::begin(r), nth, ranges::end(r), comp, proj);
```

27.8.4 Binary search

[alg.binary.search]

27.8.4.1 General

[alg.binary.search.general]

All of the algorithms in 27.8.4 are versions of binary search and assume that the sequence being searched is partitioned with respect to an expression formed by binding the search key to an argument of the comparison function. They work on non-random access iterators minimizing the number of comparisons, which will be

logarithmic for all types of iterators. They are especially appropriate for random access iterators, because these algorithms do a logarithmic number of steps through the data structure. For non-random access iterators they execute a linear number of steps.

27.8.4.2 lower_bound

[lower_bound]

```
template<class ForwardIterator, class T>
constexpr ForwardIterator
    lower_bound(ForwardIterator first, ForwardIterator last,
                const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr ForwardIterator
    lower_bound(ForwardIterator first, ForwardIterator last,
                const T& value, Compare comp);

template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity,
        indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::lower_bound(I first, S last, const T& value, Comp comp = {},
                                Proj proj = {});

template<forward_range R, class T, class Proj = identity,
        indirect_strict_weak_order<const T*, projected<iterator_t<R>, Proj>> Comp =
        ranges::less>
constexpr borrowed_iterator_t<R>
    ranges::lower_bound(R&& r, const T& value, Comp comp = {}, Proj proj = {});
```

Let `comp` be `less{}` and `proj` be `identity{}` for overloads with no parameters by those names.

Preconditions: The elements `e` of `[first, last)` are partitioned with respect to the expression `bool(invoker(comp, invoker(proj, e), value))`.

Returns: The furthestmost iterator `i` in the range `[first, last]` such that for every iterator `j` in the range `[first, i)`, `bool(invoker(comp, invoker(proj, *j), value))` is true.

Complexity: At most $\log_2(\text{last} - \text{first}) + \mathcal{O}(1)$ comparisons and projections.

27.8.4.3 upper_bound

[upper_bound]

```
template<class ForwardIterator, class T>
constexpr ForwardIterator
    upper_bound(ForwardIterator first, ForwardIterator last,
                const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr ForwardIterator
    upper_bound(ForwardIterator first, ForwardIterator last,
                const T& value, Compare comp);

template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity,
        indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::upper_bound(I first, S last, const T& value, Comp comp = {}, Proj proj = {});

template<forward_range R, class T, class Proj = identity,
        indirect_strict_weak_order<const T*, projected<iterator_t<R>, Proj>> Comp =
        ranges::less>
constexpr borrowed_iterator_t<R>
    ranges::upper_bound(R&& r, const T& value, Comp comp = {}, Proj proj = {});
```

Let `comp` be `less{}` and `proj` be `identity{}` for overloads with no parameters by those names.

Preconditions: The elements `e` of `[first, last)` are partitioned with respect to the expression `!bool(invoker(comp, value, invoker(proj, e)))`.

Returns: The furthestmost iterator `i` in the range `[first, last]` such that for every iterator `j` in the range `[first, i)`, `!bool(invoker(comp, value, invoker(proj, *j)))` is true.

Complexity: At most $\log_2(\text{last} - \text{first}) + \mathcal{O}(1)$ comparisons and projections.

27.8.4.4 equal_range

[equal.range]

```

template<class ForwardIterator, class T>
constexpr pair<ForwardIterator, ForwardIterator>
    equal_range(ForwardIterator first,
                ForwardIterator last, const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr pair<ForwardIterator, ForwardIterator>
    equal_range(ForwardIterator first,
                ForwardIterator last, const T& value,
                Compare comp);

template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity,
        indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr subrange<I>
    ranges::equal_range(I first, S last, const T& value, Comp comp = {}, Proj proj = {});
template<forward_range R, class T, class Proj = identity,
        indirect_strict_weak_order<const T*, projected<iterator_t<R>, Proj>> Comp =
        ranges::less>
constexpr borrowed_subrange_t<R>
    ranges::equal_range(R&& r, const T& value, Comp comp = {}, Proj proj = {});

```

Let `comp` be `less{}` and `proj` be `identity{}` for overloads with no parameters by those names.

Preconditions: The elements `e` of `[first,last)` are partitioned with respect to the expressions `bool(invoker(comp, invoker(proj, e), value))` and `!bool(invoker(comp, value, invoker(proj, e)))`. Also, for all elements `e` of `[first, last)`, `bool(comp(e, value))` implies `!bool(comp(value, e))` for the overloads in namespace `std`.

Returns:

- For the overloads in namespace `std`:

```

{lower_bound(first, last, value, comp),
 upper_bound(first, last, value, comp)}

```

- For the overloads in namespace `ranges`:

```

{ranges::lower_bound(first, last, value, comp, proj),
 ranges::upper_bound(first, last, value, comp, proj)}

```

Complexity: At most $2 * \log_2(\text{last} - \text{first}) + \mathcal{O}(1)$ comparisons and projections.

27.8.4.5 binary_search

[binary.search]

```

template<class ForwardIterator, class T>
constexpr bool
    binary_search(ForwardIterator first, ForwardIterator last,
                  const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr bool
    binary_search(ForwardIterator first, ForwardIterator last,
                  const T& value, Compare comp);

template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity,
        indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr bool ranges::binary_search(I first, S last, const T& value, Comp comp = {},
                                     Proj proj = {});
template<forward_range R, class T, class Proj = identity,
        indirect_strict_weak_order<const T*, projected<iterator_t<R>, Proj>> Comp =
        ranges::less>
constexpr bool ranges::binary_search(R&& r, const T& value, Comp comp = {},
                                     Proj proj = {});

```

Let `comp` be `less{}` and `proj` be `identity{}` for overloads with no parameters by those names.

Preconditions: The elements `e` of `[first,last)` are partitioned with respect to the expressions `bool(invoker(comp, invoker(proj, e), value))` and `!bool(invoker(comp, value, invoker(proj, e)))`.

e))). Also, for all elements *e* of `[first, last)`, `bool(comp(e, value))` implies `!bool(comp(value, e))` for the overloads in namespace `std`.

Returns: true if and only if for some iterator *i* in the range `[first, last)`, `!bool(invoke(comp, invoke(proj, *i), value)) && !bool(invoke(comp, value, invoke(proj, *i)))` is true.

Complexity: At most $\log_2(\text{last} - \text{first}) + \mathcal{O}(1)$ comparisons and projections.

27.8.5 Partitions

[alg.partitions]

```
template<class InputIterator, class Predicate>
constexpr bool is_partitioned(InputIterator first, InputIterator last, Predicate pred);
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool is_partitioned(ExecutionPolicy&& exec,
                   ForwardIterator first, ForwardIterator last, Predicate pred);
```

```
template<input_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr bool ranges::is_partitioned(I first, S last, Pred pred, Proj proj = {});
template<input_range R, class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr bool ranges::is_partitioned(R&& r, Pred pred, Proj proj = {});
```

Let `proj` be `identity{}` for the overloads with no parameter named `proj`.

Returns: true if and only if the elements *e* of `[first, last)` are partitioned with respect to the expression `bool(invoke(pred, invoke(proj, e)))`.

Complexity: Linear. At most `last - first` applications of `pred` and `proj`.

```
template<class ForwardIterator, class Predicate>
constexpr ForwardIterator
partition(ForwardIterator first, ForwardIterator last, Predicate pred);
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
ForwardIterator
partition(ExecutionPolicy&& exec,
         ForwardIterator first, ForwardIterator last, Predicate pred);
```

```
template<permutable I, sentinel_for<I> S, class Proj = identity,
        indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr subrange<I>
ranges::partition(I first, S last, Pred pred, Proj proj = {});
template<forward_range R, class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
requires permutable<iterator_t<R>>
constexpr borrowed_subrange_t<R>
ranges::partition(R&& r, Pred pred, Proj proj = {});
```

Let `proj` be `identity{}` for the overloads with no parameter named `proj` and let $E(x)$ be `bool(invoke(pred, invoke(proj, x)))`.

Preconditions: For the overloads in namespace `std`, `ForwardIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3).

Effects: Places all the elements *e* in `[first, last)` that satisfy $E(e)$ before all the elements that do not.

Returns: Let *i* be an iterator such that $E(*j)$ is true for every iterator *j* in `[first, i)` and false for every iterator *j* in `[i, last)`. Returns:

- *i* for the overloads in namespace `std`.
- `{i, last}` for the overloads in namespace `ranges`.

Complexity: Let $N = \text{last} - \text{first}$:

- For the overload with no `ExecutionPolicy`, exactly N applications of the predicate and projection. At most $N/2$ swaps if the type of `first` meets the *Cpp17BidirectionalIterator* requirements for the overloads in namespace `std` or models `bidirectional_iterator` for the overloads in namespace `ranges`, and at most N swaps otherwise.

- For the overload with an `ExecutionPolicy`, $\mathcal{O}(N \log N)$ swaps and $\mathcal{O}(N)$ applications of the predicate.

```
template<class BidirectionalIterator, class Predicate>
    BidirectionalIterator
        stable_partition(BidirectionalIterator first, BidirectionalIterator last, Predicate pred);
template<class ExecutionPolicy, class BidirectionalIterator, class Predicate>
    BidirectionalIterator
        stable_partition(ExecutionPolicy&& exec,
                        BidirectionalIterator first, BidirectionalIterator last, Predicate pred);

template<bidirectional_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_unary_predicate<projected<I, Proj>> Pred>
    requires permutable<I>
    subrange<I> ranges::stable_partition(I first, S last, Pred pred, Proj proj = {});
template<bidirectional_range R, class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
    requires permutable<iterator_t<R>>
    borrowed_subrange_t<R> ranges::stable_partition(R&& r, Pred pred, Proj proj = {});
```

Let `proj` be `identity{}` for the overloads with no parameter named `proj` and let $E(x)$ be `bool(invoker(pred, invoker(proj, x))).`

Preconditions: For the overloads in namespace `std`, `BidirectionalIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3) and the type of `*first` meets the *Cpp17MoveConstructible* (Table 31) and *Cpp17MoveAssignable* (Table 33) requirements.

Effects: Places all the elements `e` in `[first, last)` that satisfy $E(e)$ before all the elements that do not. The relative order of the elements in both groups is preserved.

Returns: Let `i` be an iterator such that for every iterator `j` in `[first, i)`, $E(*j)$ is true, and for every iterator `j` in the range `[i, last)`, $E(*j)$ is false. Returns:

- `i` for the overloads in namespace `std`.
- `{i, last}` for the overloads in namespace `ranges`.

Complexity: Let $N = \text{last} - \text{first}$:

- For the overloads with no `ExecutionPolicy`, at most $N \log_2 N$ swaps, but only $\mathcal{O}(N)$ swaps if there is enough extra memory. Exactly N applications of the predicate and projection.
- For the overload with an `ExecutionPolicy`, $\mathcal{O}(N \log N)$ swaps and $\mathcal{O}(N)$ applications of the predicate.

```
template<class InputIterator, class OutputIterator1, class OutputIterator2, class Predicate>
    constexpr pair<OutputIterator1, OutputIterator2>
        partition_copy(InputIterator first, InputIterator last,
                      OutputIterator1 out_true, OutputIterator2 out_false, Predicate pred);
template<class ExecutionPolicy, class ForwardIterator, class ForwardIterator1,
        class ForwardIterator2, class Predicate>
    pair<ForwardIterator1, ForwardIterator2>
        partition_copy(ExecutionPolicy&& exec,
                      ForwardIterator first, ForwardIterator last,
                      ForwardIterator1 out_true, ForwardIterator2 out_false, Predicate pred);

template<input_iterator I, sentinel_for<I> S, weakly_incrementable O1, weakly_incrementable O2,
        class Proj = identity, indirect_unary_predicate<projected<I, Proj>> Pred>
    requires indirectly_copyable<I, O1> && indirectly_copyable<I, O2>
    constexpr ranges::partition_copy_result<I, O1, O2>
        ranges::partition_copy(I first, S last, O1 out_true, O2 out_false, Pred pred,
                              Proj proj = {});
template<input_range R, weakly_incrementable O1, weakly_incrementable O2,
        class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
    requires indirectly_copyable<iterator_t<R>, O1> &&
        indirectly_copyable<iterator_t<R>, O2>
    constexpr ranges::partition_copy_result<borrowed_iterator_t<R>, O1, O2>
```

```
ranges::partition_copy(R&& r, 01 out_true, 02 out_false, Pred pred, Proj proj = {});
```

Let `proj` be `identity{}` for the overloads with no parameter named `proj` and let $E(x)$ be `bool(invoker(pred, invoke(proj, x)))`.

Mandates: For the overloads in namespace `std`, the expression `*first` is writable (25.3.1) to `out_true` and `out_false`.

Preconditions: The input range and output ranges do not overlap.

NOTE For the overload with an `ExecutionPolicy`, a performance cost is possible if `first`'s value type does not meet the *Cpp17CopyConstructible* requirements.

Effects: For each iterator `i` in `[first, last)`, copies `*i` to the output range beginning with `out_true` if $E(*i)$ is `true`, or to the output range beginning with `out_false` otherwise.

Returns: Let `o1` be the end of the output range beginning at `out_true`, and `o2` the end of the output range beginning at `out_false`. Returns

- `{o1, o2}` for the overloads in namespace `std`.
- `{last, o1, o2}` for the overloads in namespace `ranges`.

Complexity: Exactly `last - first` applications of `pred` and `proj`.

```
template<class ForwardIterator, class Predicate>
constexpr ForwardIterator
partition_point(ForwardIterator first, ForwardIterator last, Predicate pred);
```

```
template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr I ranges::partition_point(I first, S last, Pred pred, Proj proj = {});
template<forward_range R, class Proj = identity,
        indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr borrowed_iterator_t<R>
ranges::partition_point(R&& r, Pred pred, Proj proj = {});
```

Let `proj` be `identity{}` for the overloads with no parameter named `proj` and let $E(x)$ be `bool(invoker(pred, invoke(proj, x)))`.

Preconditions: The elements `e` of `[first, last)` are partitioned with respect to $E(e)$.

Returns: An iterator `mid` such that $E(*i)$ is `true` for all iterators `i` in `[first, mid)`, and `false` for all iterators `i` in `[mid, last)`.

Complexity: $\mathcal{O}(\log(\text{last} - \text{first}))$ applications of `pred` and `proj`.

27.8.6 Merge

[alg.merge]

```
template<class InputIterator1, class InputIterator2,
        class OutputIterator>
constexpr OutputIterator
merge(InputIterator1 first1, InputIterator1 last1,
      InputIterator2 first2, InputIterator2 last2,
      OutputIterator result);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class ForwardIterator>
ForwardIterator
merge(ExecutionPolicy&& exec,
      ForwardIterator1 first1, ForwardIterator1 last1,
      ForwardIterator2 first2, ForwardIterator2 last2,
      ForwardIterator result);

template<class InputIterator1, class InputIterator2,
        class OutputIterator, class Compare>
constexpr OutputIterator
merge(InputIterator1 first1, InputIterator1 last1,
      InputIterator2 first2, InputIterator2 last2,
      OutputIterator result, Compare comp);
```

```

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class ForwardIterator, class Compare>
ForwardIterator
merge(ExecutionPolicy&& exec,
      ForwardIterator1 first1, ForwardIterator1 last1,
      ForwardIterator2 first2, ForwardIterator2 last2,
      ForwardIterator result, Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
        weakly_incremmentable O, class Comp = ranges::less, class Proj1 = identity,
        class Proj2 = identity>
requires mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::merge_result<I1, I2, O>
ranges::merge(I1 first1, S1 last1, I2 first2, S2 last2, O result,
              Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, weakly_incremmentable O, class Comp = ranges::less,
        class Proj1 = identity, class Proj2 = identity>
requires mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
constexpr ranges::merge_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>, O>
ranges::merge(R1&& r1, R2&& r2, O result,
              Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

```

Let N be $(last1 - first1) + (last2 - first2)$. Let `comp` be `less{}`, `proj1` be `identity{}`, and `proj2` be `identity{}`, for the overloads with no parameters by those names.

Preconditions: The ranges $[first1, last1)$ and $[first2, last2)$ are sorted with respect to `comp` and `proj1` or `proj2`, respectively. The resulting range does not overlap with either of the original ranges.

Effects: Copies all the elements of the two ranges $[first1, last1)$ and $[first2, last2)$ into the range $[result, result\_last)$, where `result\_last` is `result + N`. If an element `a` precedes `b` in an input range, `a` is copied into the output range before `b`. If `e1` is an element of $[first1, last1)$ and `e2` of $[first2, last2)$, `e2` is copied into the output range before `e1` if and only if `bool(invoker(comp, invoker(proj2, e2), invoker(proj1, e1)))` is `true`.

Returns:

- `result\_last` for the overloads in namespace `std`.
- `{last1, last2, result\_last}` for the overloads in namespace `ranges`.

Complexity:

- For the overloads with no `ExecutionPolicy`, at most $N - 1$ comparisons and applications of each projection.
- For the overloads with an `ExecutionPolicy`, $\mathcal{O}(N)$ comparisons.

Remarks: Stable (16.4.6.8).

```

template<class BidirectionalIterator>
void inplace_merge(BidirectionalIterator first,
                  BidirectionalIterator middle,
                  BidirectionalIterator last);

template<class ExecutionPolicy, class BidirectionalIterator>
void inplace_merge(ExecutionPolicy&& exec,
                  BidirectionalIterator first,
                  BidirectionalIterator middle,
                  BidirectionalIterator last);

template<class BidirectionalIterator, class Compare>
void inplace_merge(BidirectionalIterator first,
                  BidirectionalIterator middle,
                  BidirectionalIterator last, Compare comp);

template<class ExecutionPolicy, class BidirectionalIterator, class Compare>
void inplace_merge(ExecutionPolicy&& exec,
                  BidirectionalIterator first,
                  BidirectionalIterator middle,
                  BidirectionalIterator last, Compare comp);

```

```
template<bidirectional_iterator I, sentinel_for<I> S, class Comp = ranges::less,
        class Proj = identity>
requires sortable<I, Comp, Proj>
I ranges::inplace_merge(I first, I middle, S last, Comp comp = {}, Proj proj = {});
```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

Preconditions: `[first,middle)` and `[middle,last)` are valid ranges sorted with respect to `comp` and `proj`. For the overloads in namespace `std`, `BidirectionalIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3) and the type of `*first` meets the *Cpp17MoveConstructible* (Table 31) and *Cpp17MoveAssignable* (Table 33) requirements.

Effects: Merges two sorted consecutive ranges `[first,middle)` and `[middle,last)`, putting the result of the merge into the range `[first,last)`. The resulting range is sorted with respect to `comp` and `proj`.

Returns: `last` for the overload in namespace `ranges`.

Complexity: Let $N = \text{last} - \text{first}$:

- For the overloads with no `ExecutionPolicy`, and if enough additional memory is available, exactly $N - 1$ comparisons.
- Otherwise, $\mathcal{O}(N \log N)$ comparisons.

In either case, twice as many projections as comparisons.

Remarks: Stable (16.4.6.8).

```
template<bidirectional_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
borrowed_iterator_t<R>
ranges::inplace_merge(R&& r, iterator_t<R> middle, Comp comp = {}, Proj proj = {});
```

Effects: Equivalent to:

```
return ranges::inplace_merge(ranges::begin(r), middle, ranges::end(r), comp, proj);
```

27.8.7 Set operations on sorted structures [alg.set.operations]

27.8.7.1 General [alg.set.operations.general]

Subclause 27.8.7 defines all the basic set operations on sorted structures. They also work with *multisets* (24.4.7) containing multiple copies of equivalent elements. The semantics of the set operations are generalized to *multisets* in a standard way by defining `set_union` to contain the maximum number of occurrences of every element, `set_intersection` to contain the minimum, and so on.

27.8.7.2 includes [includes]

```
template<class InputIterator1, class InputIterator2>
constexpr bool includes(InputIterator1 first1, InputIterator1 last1,
                        InputIterator2 first2, InputIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool includes(ExecutionPolicy&& exec,
              ForwardIterator1 first1, ForwardIterator1 last1,
              ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator1, class InputIterator2, class Compare>
constexpr bool includes(InputIterator1 first1, InputIterator1 last1,
                        InputIterator2 first2, InputIterator2 last2,
                        Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class Compare>
bool includes(ExecutionPolicy&& exec,
              ForwardIterator1 first1, ForwardIterator1 last1,
              ForwardIterator2 first2, ForwardIterator2 last2,
              Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
        class Proj1 = identity, class Proj2 = identity,
        indirect_strict_weak_order<projected<I1, Proj1>,
                                   projected<I2, Proj2>> Comp = ranges::less>
constexpr bool ranges::includes(I1 first1, S1 last1, I2 first2, S2 last2, Comp comp = {},
```

```

        Proj1 proj1 = {}, Proj2 proj2 = {});
template<input_range R1, input_range R2, class Proj1 = identity,
        class Proj2 = identity,
        indirect_strict_weak_order<projected<iterator_t<R1>, Proj1>,
        projected<iterator_t<R2>, Proj2>> Comp = ranges::less>
constexpr bool ranges::includes(R1&& r1, R2&& r2, Comp comp = {},
        Proj1 proj1 = {}, Proj2 proj2 = {});

```

Let `comp` be `less{}`, `proj1` be `identity{}`, and `proj2` be `identity{}`, for the overloads with no parameters by those names.

Preconditions: The ranges `[first1, last1)` and `[first2, last2)` are sorted with respect to `comp` and `proj1` or `proj2`, respectively.

Returns: `true` if and only if `[first2, last2)` is a subsequence of `[first1, last1)`.

NOTE A sequence *S* is a subsequence of another sequence *T* if *S* can be obtained from *T* by removing some, all, or none of *T*'s elements and keeping the remaining elements in the same order.

Complexity: At most $2 * ((last1 - first1) + (last2 - first2)) - 1$ comparisons and applications of each projection.

27.8.7.3 set_union

[set.union]

```

template<class InputIterator1, class InputIterator2, class OutputIterator>
constexpr OutputIterator
    set_union(InputIterator1 first1, InputIterator1 last1,
              InputIterator2 first2, InputIterator2 last2,
              OutputIterator result);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class ForwardIterator>
ForwardIterator
    set_union(ExecutionPolicy&& exec,
              ForwardIterator1 first1, ForwardIterator1 last1,
              ForwardIterator2 first2, ForwardIterator2 last2,
              ForwardIterator result);

template<class InputIterator1, class InputIterator2, class OutputIterator, class Compare>
constexpr OutputIterator
    set_union(InputIterator1 first1, InputIterator1 last1,
              InputIterator2 first2, InputIterator2 last2,
              OutputIterator result, Compare comp);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class ForwardIterator, class Compare>
ForwardIterator
    set_union(ExecutionPolicy&& exec,
              ForwardIterator1 first1, ForwardIterator1 last1,
              ForwardIterator2 first2, ForwardIterator2 last2,
              ForwardIterator result, Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
        weakly_incrementable O, class Comp = ranges::less,
        class Proj1 = identity, class Proj2 = identity>
requires mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::set_union_result<I1, I2, O>
    ranges::set_union(I1 first1, S1 last1, I2 first2, S2 last2, O result, Comp comp = {},
                      Proj1 proj1 = {}, Proj2 proj2 = {});
template<input_range R1, input_range R2, weakly_incrementable O,
        class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
constexpr ranges::set_union_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>, O>
    ranges::set_union(R1&& r1, R2&& r2, O result, Comp comp = {},
                      Proj1 proj1 = {}, Proj2 proj2 = {});

```

Let `comp` be `less{}`, and `proj1` and `proj2` be `identity{}` for the overloads with no parameters by those names.

Preconditions: The ranges $[first1, last1)$ and $[first2, last2)$ are sorted with respect to `comp` and `proj1` or `proj2`, respectively. The resulting range does not overlap with either of the original ranges.

Effects: Constructs a sorted union of the elements from the two ranges; that is, the set of elements that are present in one or both of the ranges.

Returns: Let `result_last` be the end of the constructed range. Returns

- `result_last` for the overloads in namespace `std`.
- $\{last1, last2, result\_last\}$ for the overloads in namespace `ranges`.

Complexity: At most $2 * ((last1 - first1) + (last2 - first2)) - 1$ comparisons and applications of each projection.

Remarks: Stable (16.4.6.8). If $[first1, last1)$ contains m elements that are equivalent to each other and $[first2, last2)$ contains n elements that are equivalent to them, then all m elements from the first range are copied to the output range, in order, and then the final $\max(n - m, 0)$ elements from the second range are copied to the output range, in order.

27.8.7.4 `set_intersection`

[`set.intersection`]

```
template<class InputIterator1, class InputIterator2,
        class OutputIterator>
constexpr OutputIterator
set_intersection(InputIterator1 first1, InputIterator1 last1,
                InputIterator2 first2, InputIterator2 last2,
                OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class ForwardIterator>
ForwardIterator
set_intersection(ExecutionPolicy&& exec,
                ForwardIterator1 first1, ForwardIterator1 last1,
                ForwardIterator2 first2, ForwardIterator2 last2,
                ForwardIterator result);

template<class InputIterator1, class InputIterator2,
        class OutputIterator, class Compare>
constexpr OutputIterator
set_intersection(InputIterator1 first1, InputIterator1 last1,
                InputIterator2 first2, InputIterator2 last2,
                OutputIterator result, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class ForwardIterator, class Compare>
ForwardIterator
set_intersection(ExecutionPolicy&& exec,
                ForwardIterator1 first1, ForwardIterator1 last1,
                ForwardIterator2 first2, ForwardIterator2 last2,
                ForwardIterator result, Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
        weakly_incrementable O, class Comp = ranges::less,
        class Proj1 = identity, class Proj2 = identity>
requires mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::set_intersection_result<I1, I2, O>
ranges::set_intersection(I1 first1, S1 last1, I2 first2, S2 last2, O result,
                        Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, weakly_incrementable O,
        class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
constexpr ranges::set_intersection_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>, O>
ranges::set_intersection(R1&& r1, R2&& r2, O result,
                        Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});
```

Let `comp` be `less{}`, and `proj1` and `proj2` be `identity{}` for the overloads with no parameters by those names.

Preconditions: The ranges $[first1, last1)$ and $[first2, last2)$ are sorted with respect to `comp` and `proj1` or `proj2`, respectively. The resulting range does not overlap with either of the original ranges.

Effects: Constructs a sorted intersection of the elements from the two ranges; that is, the set of elements that are present in both of the ranges.

Returns: Let `result_last` be the end of the constructed range. Returns

- `result_last` for the overloads in namespace `std`.
- $\{last1, last2, result\_last\}$ for the overloads in namespace `ranges`.

Complexity: At most $2 * ((last1 - first1) + (last2 - first2)) - 1$ comparisons and applications of each projection.

Remarks: Stable (16.4.6.8). If $[first1, last1)$ contains m elements that are equivalent to each other and $[first2, last2)$ contains n elements that are equivalent to them, the first $\min(m, n)$ elements are copied from the first range to the output range, in order.

27.8.7.5 `set_difference`

[`set.difference`]

```
template<class InputIterator1, class InputIterator2,
        class OutputIterator>
constexpr OutputIterator
    set_difference(InputIterator1 first1, InputIterator1 last1,
                  InputIterator2 first2, InputIterator2 last2,
                  OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class ForwardIterator>
ForwardIterator
    set_difference(ExecutionPolicy&& exec,
                  ForwardIterator1 first1, ForwardIterator1 last1,
                  ForwardIterator2 first2, ForwardIterator2 last2,
                  ForwardIterator result);

template<class InputIterator1, class InputIterator2,
        class OutputIterator, class Compare>
constexpr OutputIterator
    set_difference(InputIterator1 first1, InputIterator1 last1,
                  InputIterator2 first2, InputIterator2 last2,
                  OutputIterator result, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class ForwardIterator, class Compare>
ForwardIterator
    set_difference(ExecutionPolicy&& exec,
                  ForwardIterator1 first1, ForwardIterator1 last1,
                  ForwardIterator2 first2, ForwardIterator2 last2,
                  ForwardIterator result, Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
        weakly_incremmentable O, class Comp = ranges::less,
        class Proj1 = identity, class Proj2 = identity>
requires mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::set_difference_result<I1, O>
    ranges::set_difference(I1 first1, S1 last1, I2 first2, S2 last2, O result,
                          Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, weakly_incremmentable O,
        class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
constexpr ranges::set_difference_result<borrowed_iterator_t<R1>, O>
    ranges::set_difference(R1&& r1, R2&& r2, O result,
                          Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});
```

Let `comp` be `less{}`, and `proj1` and `proj2` be `identity{}` for the overloads with no parameters by those names.

Preconditions: The ranges $[first1, last1)$ and $[first2, last2)$ are sorted with respect to `comp` and `proj1` or `proj2`, respectively. The resulting range does not overlap with either of the original ranges.

Effects: Copies the elements of the range `[first1, last1)` which are not present in the range `[first2, last2)` to the range beginning at `result`. The elements in the constructed range are sorted.

Returns: Let `result_last` be the end of the constructed range. Returns

- `result_last` for the overloads in namespace `std`.
- `{last1, result_last}` for the overloads in namespace `ranges`.

Complexity: At most $2 * ((last1 - first1) + (last2 - first2)) - 1$ comparisons and applications of each projection.

Remarks: If `[first1, last1)` contains m elements that are equivalent to each other and `[first2, last2)` contains n elements that are equivalent to them, the last $\max(m - n, 0)$ elements from `[first1, last1)` are copied to the output range, in order.

27.8.7.6 `set_symmetric_difference`

[`set.symmetric.difference`]

```
template<class InputIterator1, class InputIterator2,
        class OutputIterator>
constexpr OutputIterator
set_symmetric_difference(InputIterator1 first1, InputIterator1 last1,
                        InputIterator2 first2, InputIterator2 last2,
                        OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class ForwardIterator>
ForwardIterator
set_symmetric_difference(ExecutionPolicy&& exec,
                        ForwardIterator1 first1, ForwardIterator1 last1,
                        ForwardIterator2 first2, ForwardIterator2 last2,
                        ForwardIterator result);

template<class InputIterator1, class InputIterator2,
        class OutputIterator, class Compare>
constexpr OutputIterator
set_symmetric_difference(InputIterator1 first1, InputIterator1 last1,
                        InputIterator2 first2, InputIterator2 last2,
                        OutputIterator result, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class ForwardIterator, class Compare>
ForwardIterator
set_symmetric_difference(ExecutionPolicy&& exec,
                        ForwardIterator1 first1, ForwardIterator1 last1,
                        ForwardIterator2 first2, ForwardIterator2 last2,
                        ForwardIterator result, Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
        weakly_increamentable O, class Comp = ranges::less,
        class Proj1 = identity, class Proj2 = identity>
requires mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::set_symmetric_difference_result<I1, I2, O>
ranges::set_symmetric_difference(I1 first1, S1 last1, I2 first2, S2 last2, O result,
                                Comp comp = {}, Proj1 proj1 = {},
                                Proj2 proj2 = {});

template<input_range R1, input_range R2, weakly_increamentable O,
        class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
constexpr ranges::set_symmetric_difference_result<borrowed_iterator_t<R1>,
        borrowed_iterator_t<R2>, O>
ranges::set_symmetric_difference(R1&& r1, R2&& r2, O result, Comp comp = {},
                                Proj1 proj1 = {}, Proj2 proj2 = {});
```

Let `comp` be `less{}`, and `proj1` and `proj2` be `identity{}` for the overloads with no parameters by those names.

Preconditions: The ranges `[first1, last1)` and `[first2, last2)` are sorted with respect to `comp` and `proj1` or `proj2`, respectively. The resulting range does not overlap with either of the original ranges.

Effects: Copies the elements of the range `[first1, last1)` that are not present in the range `[first2, last2)`, and the elements of the range `[first2, last2)` that are not present in the range `[first1, last1)` to the range beginning at `result`. The elements in the constructed range are sorted.

Returns: Let `result_last` be the end of the constructed range. Returns

- `result_last` for the overloads in namespace `std`.
- `{last1, last2, result_last}` for the overloads in namespace `ranges`.

Complexity: At most $2 * ((last1 - first1) + (last2 - first2)) - 1$ comparisons and applications of each projection.

Remarks: Stable (16.4.6.8). If `[first1, last1)` contains m elements that are equivalent to each other and `[first2, last2)` contains n elements that are equivalent to them, then $|m - n|$ of those elements shall be copied to the output range: the last $m - n$ of these elements from `[first1, last1)` if $m > n$, and the last $n - m$ of these elements from `[first2, last2)` if $m < n$. In either case, the elements are copied in order.

27.8.8 Heap operations

[alg.heap.operations]

27.8.8.1 General

[alg.heap.operations.general]

A random access range `[a, b)` is a *heap with respect to `comp` and `proj`* for a comparator and projection `comp` and `proj` if its elements are organized such that:

- With $N = b - a$, for all i , $0 < i < N$, `bool(invoker(comp, invoker(proj, a[ $\lfloor \frac{i-1}{2} \rfloor$ )]), invoker(proj, a[i]))` is false.
- `*a` may be removed by `pop_heap`, or a new element added by `push_heap`, in $\mathcal{O}(\log N)$ time.

These properties make heaps useful as priority queues.

`make_heap` converts a range into a heap and `sort_heap` turns a heap into a sorted sequence.

27.8.8.2 push_heap

[push.heap]

```
template<class RandomAccessIterator>
constexpr void push_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void push_heap(RandomAccessIterator first, RandomAccessIterator last,
                        Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
        class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
    ranges::push_heap(I first, S last, Comp comp = {}, Proj proj = {});

template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
    ranges::push_heap(R&& r, Comp comp = {}, Proj proj = {});
```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

Preconditions: The range `[first, last - 1)` is a valid heap with respect to `comp` and `proj`. For the overloads in namespace `std`, `RandomAccessIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3) and the type of `*first` meets the *Cpp17MoveConstructible* requirements (Table 31) and the *Cpp17MoveAssignable* requirements (Table 33).

Effects: Places the value in the location `last - 1` into the resulting heap `[first, last)`.

Returns: `last` for the overloads in namespace `ranges`.

Complexity: At most $\log(last - first)$ comparisons and twice as many projections.

27.8.8.3 pop_heap

[pop.heap]

```
template<class RandomAccessIterator>
constexpr void pop_heap(RandomAccessIterator first, RandomAccessIterator last);
```

```

template<class RandomAccessIterator, class Compare>
constexpr void pop_heap(RandomAccessIterator first, RandomAccessIterator last,
                        Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
        class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
    ranges::pop_heap(I first, S last, Comp comp = {}, Proj proj = {});
template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
    ranges::pop_heap(R&& r, Comp comp = {}, Proj proj = {});

```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

Preconditions: The range `[first,last)` is a valid non-empty heap with respect to `comp` and `proj`. For the overloads in namespace `std`, `RandomAccessIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3) and the type of `*first` meets the *Cpp17MoveConstructible* (Table 31) and *Cpp17MoveAssignable* (Table 33) requirements.

Effects: Swaps the value in the location `first` with the value in the location `last - 1` and makes `[first,last - 1)` into a heap with respect to `comp` and `proj`.

Returns: `last` for the overloads in namespace `ranges`.

Complexity: At most $2 \log(\text{last} - \text{first})$ comparisons and twice as many projections.

27.8.8.4 `make_heap`

[make.heap]

```

template<class RandomAccessIterator>
constexpr void make_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void make_heap(RandomAccessIterator first, RandomAccessIterator last,
                        Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
        class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
    ranges::make_heap(I first, S last, Comp comp = {}, Proj proj = {});
template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
    ranges::make_heap(R&& r, Comp comp = {}, Proj proj = {});

```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

Preconditions: For the overloads in namespace `std`, `RandomAccessIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3) and the type of `*first` meets the *Cpp17MoveConstructible* (Table 31) and *Cpp17MoveAssignable* (Table 33) requirements.

Effects: Constructs a heap with respect to `comp` and `proj` out of the range `[first,last)`.

Returns: `last` for the overloads in namespace `ranges`.

Complexity: At most $3(\text{last} - \text{first})$ comparisons and twice as many projections.

27.8.8.5 `sort_heap`

[sort.heap]

```

template<class RandomAccessIterator>
constexpr void sort_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void sort_heap(RandomAccessIterator first, RandomAccessIterator last,
                        Compare comp);

```

```
template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
        class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
    ranges::sort_heap(I first, S last, Comp comp = {}, Proj proj = {});
template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
    ranges::sort_heap(R&& r, Comp comp = {}, Proj proj = {});
```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

Preconditions: The range `[first, last)` is a valid heap with respect to `comp` and `proj`. For the overloads in namespace `std`, `RandomAccessIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3) and the type of `*first` meets the *Cpp17MoveConstructible* (Table 31) and *Cpp17MoveAssignable* (Table 33) requirements.

Effects: Sorts elements in the heap `[first, last)` with respect to `comp` and `proj`.

Returns: `last` for the overloads in namespace `ranges`.

Complexity: At most $2N \log N$ comparisons, where $N = \text{last} - \text{first}$, and twice as many projections.

27.8.8.6 `is_heap`

[is.heap]

```
template<class RandomAccessIterator>
constexpr bool is_heap(RandomAccessIterator first, RandomAccessIterator last);
```

Effects: Equivalent to: `return is_heap_until(first, last) == last;`

```
template<class ExecutionPolicy, class RandomAccessIterator>
bool is_heap(ExecutionPolicy&& exec,
             RandomAccessIterator first, RandomAccessIterator last);
```

Effects: Equivalent to:

```
return is_heap_until(std::forward<ExecutionPolicy>(exec), first, last) == last;
```

```
template<class RandomAccessIterator, class Compare>
constexpr bool is_heap(RandomAccessIterator first, RandomAccessIterator last,
                      Compare comp);
```

Effects: Equivalent to: `return is_heap_until(first, last, comp) == last;`

```
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
bool is_heap(ExecutionPolicy&& exec,
             RandomAccessIterator first, RandomAccessIterator last,
             Compare comp);
```

Effects: Equivalent to:

```
return is_heap_until(std::forward<ExecutionPolicy>(exec), first, last, comp) == last;
```

```
template<random_access_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr bool ranges::is_heap(I first, S last, Comp comp = {}, Proj proj = {});
template<random_access_range R, class Proj = identity,
        indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr bool ranges::is_heap(R&& r, Comp comp = {}, Proj proj = {});
```

Effects: Equivalent to: `return ranges::is_heap_until(first, last, comp, proj) == last;`

```
template<class RandomAccessIterator>
constexpr RandomAccessIterator
    is_heap_until(RandomAccessIterator first, RandomAccessIterator last);
template<class ExecutionPolicy, class RandomAccessIterator>
RandomAccessIterator
    is_heap_until(ExecutionPolicy&& exec,
                  RandomAccessIterator first, RandomAccessIterator last);
```

```

template<class RandomAccessIterator, class Compare>
constexpr RandomAccessIterator
    is_heap_until(RandomAccessIterator first, RandomAccessIterator last,
                  Compare comp);
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
RandomAccessIterator
    is_heap_until(ExecutionPolicy&& exec,
                  RandomAccessIterator first, RandomAccessIterator last,
                  Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::is_heap_until(I first, S last, Comp comp = {}, Proj proj = {});
template<random_access_range R, class Proj = identity,
        indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr borrowed_iterator_t<R>
    ranges::is_heap_until(R&& r, Comp comp = {}, Proj proj = {});

```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

Returns: The last iterator `i` in `[first, last]` for which the range `[first, i)` is a heap with respect to `comp` and `proj`.

Complexity: Linear.

27.8.9 Minimum and maximum

[alg.min.max]

```

template<class T>
constexpr const T& min(const T& a, const T& b);
template<class T, class Compare>
constexpr const T& min(const T& a, const T& b, Compare comp);

template<class T, class Proj = identity,
        indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr const T& ranges::min(const T& a, const T& b, Comp comp = {}, Proj proj = {});

```

Preconditions: For the first form, `T` meets the *Cpp17LessThanComparable* requirements (Table 29).

Returns: The smaller value. Returns the first argument when the arguments are equivalent.

Complexity: Exactly one comparison and two applications of the projection, if any.

Remarks: An invocation may explicitly specify an argument for the template parameter `T` of the overloads in namespace `std`.

```

template<class T>
constexpr T min(initializer_list<T> r);
template<class T, class Compare>
constexpr T min(initializer_list<T> r, Compare comp);

template<copyable T, class Proj = identity,
        indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr T ranges::min(initializer_list<T> r, Comp comp = {}, Proj proj = {});
template<input_range R, class Proj = identity,
        indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
requires indirectly_copyable_storable<iterator_t<R>, range_value_t<R>*>
constexpr range_value_t<R>
    ranges::min(R&& r, Comp comp = {}, Proj proj = {});

```

Preconditions: `ranges::distance(r) > 0`. For the overloads in namespace `std`, `T` meets the *Cpp17-CopyConstructible* requirements. For the first form, `T` meets the *Cpp17LessThanComparable* requirements (Table 29).

Returns: The smallest value in the input range. Returns a copy of the leftmost element when several elements are equivalent to the smallest.

Complexity: Exactly `ranges::distance(r) - 1` comparisons and twice as many applications of the projection, if any.

Remarks: An invocation may explicitly specify an argument for the template parameter `T` of the overloads in namespace `std`.

```
template<class T>
constexpr const T& max(const T& a, const T& b);
template<class T, class Compare>
constexpr const T& max(const T& a, const T& b, Compare comp);

template<class T, class Proj = identity,
        indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr const T& ranges::max(const T& a, const T& b, Comp comp = {}, Proj proj = {});
```

Preconditions: For the first form, `T` meets the *Cpp17LessThanComparable* requirements (Table 29).

Returns: The larger value. Returns the first argument when the arguments are equivalent.

Complexity: Exactly one comparison and two applications of the projection, if any.

Remarks: An invocation may explicitly specify an argument for the template parameter `T` of the overloads in namespace `std`.

```
template<class T>
constexpr T max(initializer_list<T> r);
template<class T, class Compare>
constexpr T max(initializer_list<T> r, Compare comp);

template<copyable T, class Proj = identity,
        indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr T ranges::max(initializer_list<T> r, Comp comp = {}, Proj proj = {});

template<input_range R, class Proj = identity,
        indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
requires indirectly_copyable_storable<iterator_t<R>, range_value_t<R>*>
constexpr range_value_t<R>
ranges::max(R&& r, Comp comp = {}, Proj proj = {});
```

Preconditions: `ranges::distance(r) > 0`. For the overloads in namespace `std`, `T` meets the *Cpp17-CopyConstructible* requirements. For the first form, `T` meets the *Cpp17LessThanComparable* requirements (Table 29).

Returns: The largest value in the input range. Returns a copy of the leftmost element when several elements are equivalent to the largest.

Complexity: Exactly `ranges::distance(r) - 1` comparisons and twice as many applications of the projection, if any.

Remarks: An invocation may explicitly specify an argument for the template parameter `T` of the overloads in namespace `std`.

```
template<class T>
constexpr pair<const T&, const T&> minmax(const T& a, const T& b);
template<class T, class Compare>
constexpr pair<const T&, const T&> minmax(const T& a, const T& b, Compare comp);

template<class T, class Proj = identity,
        indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr ranges::minmax_result<const T&>
ranges::minmax(const T& a, const T& b, Comp comp = {}, Proj proj = {});
```

Preconditions: For the first form, `T` meets the *Cpp17LessThanComparable* requirements (Table 29).

Returns: `{b, a}` if `b` is smaller than `a`, and `{a, b}` otherwise.

Complexity: Exactly one comparison and two applications of the projection, if any.

Remarks: An invocation may explicitly specify an argument for the template parameter `T` of the overloads in namespace `std`.

```
template<class T>
constexpr pair<T, T> minmax(initializer_list<T> t);
```

```

template<class T, class Compare>
constexpr pair<T, T> minmax(initializer_list<T> t, Compare comp);

template<copyable T, class Proj = identity,
        indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr ranges::minmax_result<T>
    ranges::minmax(initializer_list<T> r, Comp comp = {}, Proj proj = {});

template<input_range R, class Proj = identity,
        indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
requires indirectly_copyable_storable<iterator_t<R>, range_value_t<R>*>
constexpr ranges::minmax_result<range_value_t<R>>
    ranges::minmax(R&& r, Comp comp = {}, Proj proj = {});

```

Preconditions: `ranges::distance(r) > 0`. For the overloads in namespace `std`, `T` meets the *Cpp17-CopyConstructible* requirements. For the first form, type `T` meets the *Cpp17LessThanComparable* requirements (Table 29).

Returns: Let `X` be the return type. Returns `X{x, y}`, where `x` is a copy of the leftmost element with the smallest value and `y` a copy of the rightmost element with the largest value in the input range.

Complexity: At most $(3/2)\text{ranges::distance}(r)$ applications of the corresponding predicate and twice as many applications of the projection, if any.

Remarks: An invocation may explicitly specify an argument for the template parameter `T` of the overloads in namespace `std`.

```

template<class ForwardIterator>
constexpr ForwardIterator min_element(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator min_element(ExecutionPolicy&& exec,
                           ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
constexpr ForwardIterator min_element(ForwardIterator first, ForwardIterator last,
                                     Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class Compare>
ForwardIterator min_element(ExecutionPolicy&& exec,
                           ForwardIterator first, ForwardIterator last, Compare comp);

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::min_element(I first, S last, Comp comp = {}, Proj proj = {});

template<forward_range R, class Proj = identity,
        indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr borrowed_iterator_t<R>
    ranges::min_element(R&& r, Comp comp = {}, Proj proj = {});

```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

Returns: The first iterator `i` in the range `[first,last)` such that for every iterator `j` in the range `[first,last)`,

```

bool(involve(comp, involve(proj, *j), involve(proj, *i)))
is false. Returns last if first == last.

```

Complexity: Exactly $\max(\text{last} - \text{first} - 1, 0)$ comparisons and twice as many projections.

```

template<class ForwardIterator>
constexpr ForwardIterator max_element(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator max_element(ExecutionPolicy&& exec,
                           ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
constexpr ForwardIterator max_element(ForwardIterator first, ForwardIterator last,
                                     Compare comp);

```

```

template<class ExecutionPolicy, class ForwardIterator, class Compare>
ForwardIterator max_element(ExecutionPolicy&& exec,
                           ForwardIterator first, ForwardIterator last,
                           Compare comp);

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::max_element(I first, S last, Comp comp = {}, Proj proj = {});
template<forward_range R, class Proj = identity,
        indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr borrowed_iterator_t<R>
ranges::max_element(R&& r, Comp comp = {}, Proj proj = {});

```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

Returns: The first iterator `i` in the range `[first,last)` such that for every iterator `j` in the range `[first,last)`,

`bool(invoker(comp, invoker(proj, *i), invoker(proj, *j)))`

is false. Returns `last` if `first == last`.

Complexity: Exactly $\max(\text{last} - \text{first} - 1, 0)$ comparisons and twice as many projections.

```

template<class ForwardIterator>
constexpr pair<ForwardIterator, ForwardIterator>
minmax_element(ForwardIterator first, ForwardIterator last);
template<class ExecutionPolicy, class ForwardIterator>
pair<ForwardIterator, ForwardIterator>
minmax_element(ExecutionPolicy&& exec,
               ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
constexpr pair<ForwardIterator, ForwardIterator>
minmax_element(ForwardIterator first, ForwardIterator last, Compare comp);
template<class ExecutionPolicy, class ForwardIterator, class Compare>
pair<ForwardIterator, ForwardIterator>
minmax_element(ExecutionPolicy&& exec,
               ForwardIterator first, ForwardIterator last, Compare comp);

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
        indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr ranges::minmax_element_result<I>
ranges::minmax_element(I first, S last, Comp comp = {}, Proj proj = {});
template<forward_range R, class Proj = identity,
        indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr ranges::minmax_element_result<borrowed_iterator_t<R>>
ranges::minmax_element(R&& r, Comp comp = {}, Proj proj = {});

```

Returns: `{first, first}` if `[first,last)` is empty, otherwise `{m, M}`, where `m` is the first iterator in `[first,last)` such that no iterator in the range refers to a smaller element, and where `M` is the last iterator²¹⁸ in `[first,last)` such that no iterator in the range refers to a larger element.

Complexity: Let N be `last - first`. At most $\max(\lfloor \frac{3}{2}(N-1) \rfloor, 0)$ comparisons and twice as many applications of the projection, if any.

27.8.10 Bounded value

[alg.clamp]

```

template<class T>
constexpr const T& clamp(const T& v, const T& lo, const T& hi);
template<class T, class Compare>
constexpr const T& clamp(const T& v, const T& lo, const T& hi, Compare comp);

```

²¹⁸) This behavior intentionally differs from `max_element`.

```
template<class T, class Proj = identity,
        indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr const T&
ranges::clamp(const T& v, const T& lo, const T& hi, Comp comp = {}, Proj proj = {});
```

Let `comp` be `less{}` for the overloads with no parameter `comp`, and let `proj` be `identity{}` for the overloads with no parameter `proj`.

Preconditions: `bool(invoker(comp, invoker(proj, hi), invoker(proj, lo)))` is false. For the first form, type `T` meets the *Cpp17LessThanComparable* requirements (Table 29).

Returns: `lo` if `bool(invoker(comp, invoker(proj, v), invoker(proj, lo)))` is true, `hi` if `bool(invoker(comp, invoker(proj, hi), invoker(proj, v)))` is true, otherwise `v`.

NOTE If NaN is avoided, `T` can be a floating-point type.

Complexity: At most two comparisons and three applications of the projection.

27.8.11 Lexicographical comparison

[alg.lex.comparison]

```
template<class InputIterator1, class InputIterator2>
constexpr bool
lexicographical_compare(InputIterator1 first1, InputIterator1 last1,
                        InputIterator2 first2, InputIterator2 last2);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool
lexicographical_compare(ExecutionPolicy&& exec,
                        ForwardIterator1 first1, ForwardIterator1 last1,
                        ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator1, class InputIterator2, class Compare>
constexpr bool
lexicographical_compare(InputIterator1 first1, InputIterator1 last1,
                        InputIterator2 first2, InputIterator2 last2,
                        Compare comp);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class Compare>
bool
lexicographical_compare(ExecutionPolicy&& exec,
                        ForwardIterator1 first1, ForwardIterator1 last1,
                        ForwardIterator2 first2, ForwardIterator2 last2,
                        Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
        class Proj1 = identity, class Proj2 = identity,
        indirect_strict_weak_order<projected<I1, Proj1>,
        projected<I2, Proj2>> Comp = ranges::less>
constexpr bool
ranges::lexicographical_compare(I1 first1, S1 last1, I2 first2, S2 last2,
                                Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});
template<input_range R1, input_range R2, class Proj1 = identity,
        class Proj2 = identity,
        indirect_strict_weak_order<projected<iterator_t<R1>, Proj1>,
        projected<iterator_t<R2>, Proj2>> Comp = ranges::less>
constexpr bool
ranges::lexicographical_compare(R1&& r1, R2&& r2, Comp comp = {},
                                Proj1 proj1 = {}, Proj2 proj2 = {});
```

Returns: true if and only if the sequence of elements defined by the range `[first1, last1)` is lexicographically less than the sequence of elements defined by the range `[first2, last2)`.

Complexity: At most $2 \min(\text{last1} - \text{first1}, \text{last2} - \text{first2})$ applications of the corresponding comparison and each projection, if any.

Remarks: If two sequences have the same number of elements and their corresponding elements (if any) are equivalent, then neither sequence is lexicographically less than the other. If one sequence is a proper prefix of the other, then the shorter sequence is lexicographically less than the longer sequence.

Otherwise, the lexicographical comparison of the sequences yields the same result as the comparison of the first corresponding pair of elements that are not equivalent.

EXAMPLE `ranges::lexicographical_compare(I1, S1, I2, S2, Comp, Proj1, Proj2)` can be implemented as:

```
for ( ; first1 != last1 && first2 != last2 ; ++first1, (void) ++first2) {
    if (invoke(comp, invoke(proj1, *first1), invoke(proj2, *first2))) return true;
    if (invoke(comp, invoke(proj2, *first2), invoke(proj1, *first1))) return false;
}
return first1 == last1 && first2 != last2;
```

NOTE An empty sequence is lexicographically less than any non-empty sequence, but not less than any empty sequence.

27.8.12 Three-way comparison algorithms

[alg.three.way]

```
template<class InputIterator1, class InputIterator2, class Cmp>
```

```
constexpr auto
```

```
lexicographical_compare_three_way(InputIterator1 b1, InputIterator1 e1,
                                   InputIterator2 b2, InputIterator2 e2,
                                   Cmp comp)
```

```
-> decltype(comp(*b1, *b2));
```

Let N be $\min(e1 - b1, e2 - b2)$. Let $E(n)$ be $\text{comp}(*(b1 + n), *(b2 + n))$.

Mandates: $\text{decltype}(\text{comp}(*b1, *b2))$ is a comparison category type.

Returns: $E(i)$, where i is the smallest integer in $[0, N)$ such that $E(i) \neq 0$ is true, or $(e1 - b1) <= (e2 - b2)$ if no such integer exists.

Complexity: At most N applications of `comp`.

```
template<class InputIterator1, class InputIterator2>
```

```
constexpr auto
```

```
lexicographical_compare_three_way(InputIterator1 b1, InputIterator1 e1,
                                   InputIterator2 b2, InputIterator2 e2);
```

Effects: Equivalent to:

```
return lexicographical_compare_three_way(b1, e1, b2, e2, compare_three_way());
```

27.8.13 Permutation generators

[alg.permutation.generators]

```
template<class BidirectionalIterator>
```

```
constexpr bool next_permutation(BidirectionalIterator first,
                                BidirectionalIterator last);
```

```
template<class BidirectionalIterator, class Compare>
```

```
constexpr bool next_permutation(BidirectionalIterator first,
                                BidirectionalIterator last, Compare comp);
```

```
template<bidirectional_iterator I, sentinel_for<I> S, class Comp = ranges::less,
        class Proj = identity>
```

```
requires sortable<I, Comp, Proj>
```

```
constexpr ranges::next_permutation_result<I>
```

```
ranges::next_permutation(I first, S last, Comp comp = {}, Proj proj = {});
```

```
template<bidirectional_range R, class Comp = ranges::less,
```

```
        class Proj = identity>
```

```
requires sortable<iterator_t<R>, Comp, Proj>
```

```
constexpr ranges::next_permutation_result<borrowed_iterator_t<R>>
```

```
ranges::next_permutation(R&& r, Comp comp = {}, Proj proj = {});
```

Let `comp` be `less{}` and `proj` be `identity{}` for overloads with no parameters by those names.

Preconditions: For the overloads in namespace `std`, `BidirectionalIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3).

Effects: Takes a sequence defined by the range `[first, last)` and transforms it into the next permutation. The next permutation is found by assuming that the set of all permutations is lexicographically sorted

with respect to `comp` and `proj`. If no such permutation exists, transforms the sequence into the first permutation; that is, the ascendingly-sorted one.

Returns: Let `B` be `true` if a next permutation was found and otherwise `false`. Returns:

- `B` for the overloads in namespace `std`.
- `{ last, B }` for the overloads in namespace `ranges`.

Complexity: At most $(\text{last} - \text{first}) / 2$ swaps.

```
template<class BidirectionalIterator>
constexpr bool prev_permutation(BidirectionalIterator first,
                                BidirectionalIterator last);

template<class BidirectionalIterator, class Compare>
constexpr bool prev_permutation(BidirectionalIterator first,
                                BidirectionalIterator last, Compare comp);

template<bidirectional_iterator I, sentinel_for<I> S, class Comp = ranges::less,
        class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr ranges::prev_permutation_result<I>
    ranges::prev_permutation(I first, S last, Comp comp = {}, Proj proj = {});
template<bidirectional_range R, class Comp = ranges::less,
        class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr ranges::prev_permutation_result<borrowed_iterator_t<R>>
    ranges::prev_permutation(R&& r, Comp comp = {}, Proj proj = {});
```

Let `comp` be `less{}` and `proj` be `identity{}` for overloads with no parameters by those names.

Preconditions: For the overloads in namespace `std`, `BidirectionalIterator` meets the *Cpp17ValueSwappable* requirements (16.4.4.3).

Effects: Takes a sequence defined by the range `[first, last)` and transforms it into the previous permutation. The previous permutation is found by assuming that the set of all permutations is lexicographically sorted with respect to `comp` and `proj`. If no such permutation exists, transforms the sequence into the last permutation; that is, the descendingly-sorted one.

Returns: Let `B` be `true` if a previous permutation was found and otherwise `false`. Returns:

- `B` for the overloads in namespace `std`.
- `{ last, B }` for the overloads in namespace `ranges`.

Complexity: At most $(\text{last} - \text{first}) / 2$ swaps.

27.9 Header `<numeric>` synopsis

[numeric.ops.overview]

template<class T>
constexpr T* midpoint(T* a, T* b);
}

```

27.10 Generalized numeric operations [numeric.ops]

27.10.1 General [numeric.ops.general]

NOTE The use of closed ranges as well as semi-open ranges to specify requirements throughout 27.10 is intentional.

27.10.2 Definitions [numeric.defns]

Define *GENERALIZED_NONCOMMUTATIVE_SUM*(op, a1, ..., aN) as follows:

- a1 when N is 1, otherwise
- op(*GENERALIZED_NONCOMMUTATIVE_SUM*(op, a1, ..., aK),
GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN)) for any K where $1 < K + 1 = M \leq N$.

Define *GENERALIZED_SUM*(op, a1, ..., aN) as *GENERALIZED_NONCOMMUTATIVE_SUM*(op, b1, ..., bN), where b1, ..., bN may be any permutation of a1, ..., aN.

27.10.3 Accumulate [accumulate]

```

template<class InputIterator, class T>
constexpr T accumulate(InputIterator first, InputIterator last, T init);
template<class InputIterator, class T, class BinaryOperation>
constexpr T accumulate(InputIterator first, InputIterator last, T init,
    BinaryOperation binary_op);

```

Preconditions: T meets the *Cpp17CopyConstructible* (Table 32) and *Cpp17CopyAssignable* (Table 34) requirements. In the range [first, last], binary_op neither modifies elements nor invalidates iterators or subranges.²¹⁹

Effects: Computes its result by initializing the accumulator acc with the initial value init and then modifies it with acc = std::move(acc) + *i or acc = binary_op(std::move(acc), *i) for every iterator i in the range [first, last) in order.²²⁰

27.10.4 Reduce [reduce]

```

template<class InputIterator>
constexpr typename iterator_traits<InputIterator>::value_type
    reduce(InputIterator first, InputIterator last);

Effects: Equivalent to:

    return reduce(first, last,
        typename iterator_traits<InputIterator>::value_type{});

```

²¹⁹) The use of fully closed ranges is intentional.

²²⁰) *accumulate* is similar to the APL reduction operator and Common Lisp reduce function, but it avoids the difficulty of defining the result of reduction on an empty sequence by always requiring an initial value.

```
template<class ExecutionPolicy, class ForwardIterator>
typename iterator_traits<ForwardIterator>::value_type
reduce(ExecutionPolicy&& exec,
       ForwardIterator first, ForwardIterator last);
```

Effects: Equivalent to:

```
return reduce(std::forward<ExecutionPolicy>(exec), first, last,
             typename iterator_traits<ForwardIterator>::value_type{});
```

```
template<class InputIterator, class T>
constexpr T reduce(InputIterator first, InputIterator last, T init);
```

Effects: Equivalent to:

```
return reduce(first, last, init, plus<>());
```

```
template<class ExecutionPolicy, class ForwardIterator, class T>
T reduce(ExecutionPolicy&& exec,
        ForwardIterator first, ForwardIterator last, T init);
```

Effects: Equivalent to:

```
return reduce(std::forward<ExecutionPolicy>(exec), first, last, init, plus<>());
```

```
template<class InputIterator, class T, class BinaryOperation>
constexpr T reduce(InputIterator first, InputIterator last, T init,
                  BinaryOperation binary_op);
```

```
template<class ExecutionPolicy, class ForwardIterator, class T, class BinaryOperation>
T reduce(ExecutionPolicy&& exec,
        ForwardIterator first, ForwardIterator last, T init,
        BinaryOperation binary_op);
```

Mandates: All of

- `binary_op`(init, *first),
- `binary_op`(*first, init),
- `binary_op`(init, init), and
- `binary_op`(*first, *first)

are convertible to `T`.

Preconditions:

- `T` meets the *Cpp17MoveConstructible* (Table 31) requirements.
- `binary_op` neither invalidates iterators or subranges, nor modifies elements in the range `[first, last]`.

Returns: `GENERALIZED_SUM(binary_op, init, *i, ...)` for every `i` in `[first, last)`.

Complexity: $O(\text{last} - \text{first})$ applications of `binary_op`.

NOTE The difference between `reduce` and `accumulate` is that `reduce` applies `binary_op` in an unspecified order, which yields a nondeterministic result for non-associative or non-commutative `binary_op` such as floating-point addition.

27.10.5 Inner product

[inner.product]

```
template<class InputIterator1, class InputIterator2, class T>
constexpr T inner_product(InputIterator1 first1, InputIterator1 last1,
                          InputIterator2 first2, T init);
template<class InputIterator1, class InputIterator2, class T,
        class BinaryOperation1, class BinaryOperation2>
constexpr T inner_product(InputIterator1 first1, InputIterator1 last1,
                          InputIterator2 first2, T init,
                          BinaryOperation1 binary_op1,
                          BinaryOperation2 binary_op2);
```

Preconditions: `T` meets the *Cpp17CopyConstructible* (Table 32) and *Cpp17CopyAssignable* (Table 34) requirements. In the ranges `[first1, last1]` and `[first2, first2 + (last1 - first1)]` `binary_op1`

and `binary_op2` neither modifies elements nor invalidates iterators or subranges.²²¹

Effects: Computes its result by initializing the accumulator `acc` with the initial value `init` and then modifying it with `acc = std::move(acc) + (*i1) * (*i2)` or `acc = binary_op1(std::move(acc), binary_op2(*i1, *i2))` for every iterator `i1` in the range `[first1, last1)` and iterator `i2` in the range `[first2, first2 + (last1 - first1))` in order.

27.10.6 Transform reduce

[transform.reduce]

```
template<class InputIterator1, class InputIterator2, class T>
constexpr T transform_reduce(InputIterator1 first1, InputIterator1 last1,
                             InputIterator2 first2,
                             T init);
```

Effects: Equivalent to:

```
return transform_reduce(first1, last1, first2, init, plus<>(), multiplies<>());
```

```
template<class ExecutionPolicy,
         class ForwardIterator1, class ForwardIterator2, class T>
T transform_reduce(ExecutionPolicy&& exec,
                  ForwardIterator1 first1, ForwardIterator1 last1,
                  ForwardIterator2 first2,
                  T init);
```

Effects: Equivalent to:

```
return transform_reduce(std::forward<ExecutionPolicy>(exec),
                       first1, last1, first2, init, plus<>(), multiplies<>());
```

```
template<class InputIterator1, class InputIterator2, class T,
         class BinaryOperation1, class BinaryOperation2>
constexpr T transform_reduce(InputIterator1 first1, InputIterator1 last1,
                             InputIterator2 first2,
                             T init,
                             BinaryOperation1 binary_op1,
                             BinaryOperation2 binary_op2);
```

```
template<class ExecutionPolicy,
         class ForwardIterator1, class ForwardIterator2, class T,
         class BinaryOperation1, class BinaryOperation2>
T transform_reduce(ExecutionPolicy&& exec,
                  ForwardIterator1 first1, ForwardIterator1 last1,
                  ForwardIterator2 first2,
                  T init,
                  BinaryOperation1 binary_op1,
                  BinaryOperation2 binary_op2);
```

Mandates: All of

- `binary_op1`(`init`, `init`),
- `binary_op1`(`init`, `binary_op2(*first1, *first2)`),
- `binary_op1`(`binary_op2(*first1, *first2)`, `init`), and
- `binary_op1`(`binary_op2(*first1, *first2)`, `binary_op2(*first1, *first2)`)

are convertible to `T`.

Preconditions:

- `T` meets the *Cpp17MoveConstructible* (Table 31) requirements.
- Neither `binary_op1` nor `binary_op2` invalidates subranges, nor modifies elements in the ranges `[first1, last1]` and `[first2, first2 + (last1 - first1)]`.

Returns:

```
GENERALIZED_SUM(binary_op1, init, binary_op2(*i, *(first2 + (i - first1))), ...)
```

for every iterator `i` in `[first1, last1)`.

²²¹) The use of fully closed ranges is intentional.

Complexity: $\mathcal{O}(\text{last1} - \text{first1})$ applications each of `binary_op1` and `binary_op2`.

```
template<class InputIterator, class T,
        class BinaryOperation, class UnaryOperation>
constexpr T transform_reduce(InputIterator first, InputIterator last, T init,
                            BinaryOperation binary_op, UnaryOperation unary_op);

template<class ExecutionPolicy,
        class ForwardIterator, class T,
        class BinaryOperation, class UnaryOperation>
T transform_reduce(ExecutionPolicy&& exec,
                  ForwardIterator first, ForwardIterator last,
                  T init, BinaryOperation binary_op, UnaryOperation unary_op);
```

Mandates: All of

- `binary_op(init, init)`,
- `binary_op(init, unary_op(*first))`,
- `binary_op(unary_op(*first), init)`, and
- `binary_op(unary_op(*first), unary_op(*first))`

are convertible to `T`.

Preconditions:

- `T` meets the *Cpp17MoveConstructible* (Table 31) requirements.
- Neither `unary_op` nor `binary_op` invalidates subranges, nor modifies elements in the range `[first, last]`.

Returns:

`GENERALIZED_SUM(binary_op, init, unary_op(*i), ...)`

for every iterator `i` in `[first, last)`.

Complexity: $\mathcal{O}(\text{last} - \text{first})$ applications each of `unary_op` and `binary_op`.

NOTE `transform_reduce` does not apply `unary_op` to `init`.

27.10.7 Partial sum

[partial.sum]

```
template<class InputIterator, class OutputIterator>
constexpr OutputIterator
partial_sum(InputIterator first, InputIterator last,
            OutputIterator result);

template<class InputIterator, class OutputIterator, class BinaryOperation>
constexpr OutputIterator
partial_sum(InputIterator first, InputIterator last,
            OutputIterator result, BinaryOperation binary_op);
```

Mandates: `InputIterator`'s value type is constructible from `*first`. The result of the expression `std::move(acc) + *i` or `binary_op(std::move(acc), *i)` is implicitly convertible to `InputIterator`'s value type. `acc` is writable (25.3.1) to `result`.

Preconditions: In the ranges `[first, last]` and `[result, result + (last - first)]` `binary_op` neither modifies elements nor invalidates iterators or subranges. ²²²

Effects: For a non-empty range, the function creates an accumulator `acc` whose type is `InputIterator`'s value type, initializes it with `*first`, and assigns the result to `*result`. For every iterator `i` in `[first + 1, last)` in order, `acc` is then modified by `acc = std::move(acc) + *i` or `acc = binary_op(std::move(acc), *i)` and the result is assigned to `*(result + (i - first))`.

Returns: `result + (last - first)`.

Complexity: Exactly $(\text{last} - \text{first}) - 1$ applications of the binary operation.

Remarks: `result` may be equal to `first`.

²²²) The use of fully closed ranges is intentional.

27.10.8 Exclusive scan

[exclusive.scan]

```
template<class InputIterator, class OutputIterator, class T>
constexpr OutputIterator
exclusive_scan(InputIterator first, InputIterator last,
               OutputIterator result, T init);
```

Effects: Equivalent to:

```
return exclusive_scan(first, last, result, init, plus<>());
```

```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T>
ForwardIterator2
exclusive_scan(ExecutionPolicy&& exec,
               ForwardIterator1 first, ForwardIterator1 last,
               ForwardIterator2 result, T init);
```

Effects: Equivalent to:

```
return exclusive_scan(std::forward<ExecutionPolicy>(exec),
                     first, last, result, init, plus<>());
```

```
template<class InputIterator, class OutputIterator, class T, class BinaryOperation>
constexpr OutputIterator
exclusive_scan(InputIterator first, InputIterator last,
               OutputIterator result, T init, BinaryOperation binary_op);
template<class ExecutionPolicy,
         class ForwardIterator1, class ForwardIterator2, class T, class BinaryOperation>
ForwardIterator2
exclusive_scan(ExecutionPolicy&& exec,
               ForwardIterator1 first, ForwardIterator1 last,
               ForwardIterator2 result, T init, BinaryOperation binary_op);
```

Mandates: All of

- `binary_op`(`init`, `init`),
- `binary_op`(`init`, `*first`), and
- `binary_op`(`*first`, `*first`)

are convertible to `T`.

Preconditions:

- `T` meets the *Cpp17MoveConstructible* (Table 31) requirements.
- `binary_op` neither invalidates iterators or subranges, nor modifies elements in the ranges [`first`, `last`] or [`result`, `result + (last - first)`].

Effects: For each integer `K` in $[0, \text{last} - \text{first})$ assigns through `result + K` the value of:

```
GENERALIZED_NONCOMMUTATIVE_SUM(
    binary_op, init, *(first + 0), *(first + 1), ..., *(first + K - 1))
```

Returns: The end of the resulting range beginning at `result`.

Complexity: $\mathcal{O}(\text{last} - \text{first})$ applications of `binary_op`.

Remarks: `result` may be equal to `first`.

NOTE The difference between `exclusive_scan` and `inclusive_scan` is that `exclusive_scan` excludes the i^{th} input element from the i^{th} sum. If `binary_op` is not mathematically associative, the behavior of `exclusive_scan` can be nondeterministic.

27.10.9 Inclusive scan

[inclusive.scan]

```
template<class InputIterator, class OutputIterator>
constexpr OutputIterator
inclusive_scan(InputIterator first, InputIterator last,
               OutputIterator result);
```

Effects: Equivalent to:

```
return inclusive_scan(first, last, result, plus<>());
```

```

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
    inclusive_scan(ExecutionPolicy&& exec,
                  ForwardIterator1 first, ForwardIterator1 last,
                  ForwardIterator2 result);

Effects: Equivalent to:

    return inclusive_scan(std::forward<ExecutionPolicy>(exec), first, last, result, plus<>());

template<class InputIterator, class OutputIterator, class BinaryOperation>
constexpr OutputIterator
    inclusive_scan(InputIterator first, InputIterator last,
                  OutputIterator result, BinaryOperation binary_op);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class BinaryOperation>
ForwardIterator2
    inclusive_scan(ExecutionPolicy&& exec,
                  ForwardIterator1 first, ForwardIterator1 last,
                  ForwardIterator2 result, BinaryOperation binary_op);

template<class InputIterator, class OutputIterator, class BinaryOperation, class T>
constexpr OutputIterator
    inclusive_scan(InputIterator first, InputIterator last,
                  OutputIterator result, BinaryOperation binary_op, T init);
template<class ExecutionPolicy,
        class ForwardIterator1, class ForwardIterator2, class BinaryOperation, class T>
ForwardIterator2
    inclusive_scan(ExecutionPolicy&& exec,
                  ForwardIterator1 first, ForwardIterator1 last,
                  ForwardIterator2 result, BinaryOperation binary_op, T init);

```

Let *U* be the value type of `decltype(first)`.

Mandates: If *init* is provided, all of

- `binary_op(init, init)`,
- `binary_op(init, *first)`, and
- `binary_op(*first, *first)`;

are convertible to *T*; otherwise, `binary_op(*first, *first)` is convertible to *U*.

Preconditions:

- If *init* is provided, *T* meets the *Cpp17MoveConstructible* (Table 31) requirements; otherwise, *U* meets the *Cpp17MoveConstructible* requirements.
- `binary_op` neither invalidates iterators or subranges, nor modifies elements in the ranges [*first*, *last*] or [*result*, *result* + (*last* - *first*)].

Effects: For each integer *K* in [0, *last* - *first*) assigns through *result* + *K* the value of

- `GENERALIZED_NONCOMMUTATIVE_SUM(`
`binary_op, init, *(first + 0), *(first + 1), ..., *(first + K))`
if *init* is provided, or
- `GENERALIZED_NONCOMMUTATIVE_SUM(`
`binary_op, *(first + 0), *(first + 1), ..., *(first + K))`
otherwise.

Returns: The end of the resulting range beginning at *result*.

Complexity: $\mathcal{O}(\text{last} - \text{first})$ applications of `binary_op`.

Remarks: *result* may be equal to *first*.

NOTE The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the i^{th} input element in the i^{th} sum. If `binary_op` is not mathematically associative, the behavior of `inclusive_scan` can be nondeterministic.

27.10.10 Transform exclusive scan

[transform.exclusive.scan]

```

template<class InputIterator, class OutputIterator, class T,
        class BinaryOperation, class UnaryOperation>
constexpr OutputIterator
    transform_exclusive_scan(InputIterator first, InputIterator last,
                            OutputIterator result, T init,
                            BinaryOperation binary_op, UnaryOperation unary_op);

template<class ExecutionPolicy,
        class ForwardIterator1, class ForwardIterator2, class T,
        class BinaryOperation, class UnaryOperation>
ForwardIterator2
    transform_exclusive_scan(ExecutionPolicy&& exec,
                            ForwardIterator1 first, ForwardIterator1 last,
                            ForwardIterator2 result, T init,
                            BinaryOperation binary_op, UnaryOperation unary_op);

```

Mandates: All of

- `binary_op`(`init`, `init`),
- `binary_op`(`init`, `unary_op`(*`first`)), and
- `binary_op`(`unary_op`(*`first`), `unary_op`(*`first`))

are convertible to `T`.

Preconditions:

- `T` meets the *Cpp17MoveConstructible* (Table 31) requirements.
- Neither `unary_op` nor `binary_op` invalidates iterators or subranges, nor modifies elements in the ranges [`first`,`last`] or [`result`,`result` + (`last` - `first`)).

Effects: For each integer `K` in $[0, \text{last} - \text{first})$ assigns through `result` + `K` the value of:

```

GENERALIZED_NONCOMMUTATIVE_SUM(
    binary_op, init,
    unary_op(*(first + 0)), unary_op(*(first + 1)), ..., unary_op(*(first + K - 1)))

```

Returns: The end of the resulting range beginning at `result`.

Complexity: $\mathcal{O}(\text{last} - \text{first})$ applications each of `unary_op` and `binary_op`.

Remarks: `result` may be equal to `first`.

NOTE The difference between `transform_exclusive_scan` and `transform_inclusive_scan` is that `transform_exclusive_scan` excludes the i^{th} input element from the i^{th} sum. If `binary_op` is not mathematically associative, the behavior of `transform_exclusive_scan` can be nondeterministic. `transform_exclusive_scan` does not apply `unary_op` to `init`.

27.10.11 Transform inclusive scan

[transform.inclusive.scan]

```

template<class InputIterator, class OutputIterator,
        class BinaryOperation, class UnaryOperation>
constexpr OutputIterator
    transform_inclusive_scan(InputIterator first, InputIterator last,
                            OutputIterator result,
                            BinaryOperation binary_op, UnaryOperation unary_op);

template<class ExecutionPolicy,
        class ForwardIterator1, class ForwardIterator2,
        class BinaryOperation, class UnaryOperation>
ForwardIterator2
    transform_inclusive_scan(ExecutionPolicy&& exec,
                            ForwardIterator1 first, ForwardIterator1 last,
                            ForwardIterator2 result,
                            BinaryOperation binary_op, UnaryOperation unary_op);

template<class InputIterator, class OutputIterator,
        class BinaryOperation, class UnaryOperation, class T>
constexpr OutputIterator
    transform_inclusive_scan(InputIterator first, InputIterator last,
                            OutputIterator result,

```

```

        BinaryOperation binary_op, UnaryOperation unary_op,
        T init);
template<class ExecutionPolicy,
        class ForwardIterator1, class ForwardIterator2,
        class BinaryOperation, class UnaryOperation, class T>
ForwardIterator2
transform_inclusive_scan(ExecutionPolicy&& exec,
                        ForwardIterator1 first, ForwardIterator1 last,
                        ForwardIterator2 result,
                        BinaryOperation binary_op, UnaryOperation unary_op,
                        T init);

```

Let U be the value type of `decltype(first)`.

Mandates: If `init` is provided, all of

- `binary_op(init, init)`,
- `binary_op(init, unary_op(*first))`, and
- `binary_op(unary_op(*first), unary_op(*first))`

are convertible to T; otherwise, `binary_op(unary_op(*first), unary_op(*first))` is convertible to U.

Preconditions:

- If `init` is provided, T meets the *Cpp17MoveConstructible* (Table 31) requirements; otherwise, U meets the *Cpp17MoveConstructible* requirements.
- Neither `unary_op` nor `binary_op` invalidates iterators or subranges, nor modifies elements in the ranges `[first, last]` or `[result, result + (last - first)]`.

Effects: For each integer K in `[0, last - first)` assigns through `result + K` the value of

- `GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, unary_op(*(first + 0)), unary_op(*(first + 1)), ..., unary_op(*(first + K)))` if `init` is provided, or
- `GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, unary_op(*(first + 0)), unary_op(*(first + 1)), ..., unary_op(*(first + K)))` otherwise.

Returns: The end of the resulting range beginning at `result`.

Complexity: $\mathcal{O}(\text{last} - \text{first})$ applications each of `unary_op` and `binary_op`.

Remarks: `result` may be equal to `first`.

NOTE The difference between `transform_exclusive_scan` and `transform_inclusive_scan` is that `transform_inclusive_scan` includes the i^{th} input element in the i^{th} sum. If `binary_op` is not mathematically associative, the behavior of `transform_inclusive_scan` can be nondeterministic. `transform_inclusive_scan` does not apply `unary_op` to `init`.

27.10.12 Adjacent difference

[adjacent.difference]

```

template<class InputIterator, class OutputIterator>
constexpr OutputIterator
adjacent_difference(InputIterator first, InputIterator last,
                    OutputIterator result);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
adjacent_difference(ExecutionPolicy&& exec,
                    ForwardIterator1 first, ForwardIterator1 last, ForwardIterator2 result);

template<class InputIterator, class OutputIterator, class BinaryOperation>
constexpr OutputIterator
adjacent_difference(InputIterator first, InputIterator last,
                    OutputIterator result, BinaryOperation binary_op);

```

```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class BinaryOperation>
ForwardIterator2
adjacent_difference(ExecutionPolicy&& exec,
                   ForwardIterator1 first, ForwardIterator1 last,
                   ForwardIterator2 result, BinaryOperation binary_op);
```

Let *T* be the value type of `decltype(first)`. For the overloads that do not take an argument `binary_op`, let `binary_op` be an lvalue that denotes an object of type `minus<>`.

Mandates:

- For the overloads with no `ExecutionPolicy`, *T* is constructible from `*first`. `acc` (defined below) is writable (25.3.1) to the `result` output iterator. The result of the expression `binary_op(val, std::move(acc))` is writable to `result`.
- For the overloads with an `ExecutionPolicy`, the result of the expressions `binary_op(*first, *first)` and `*first` are writable to `result`.

Preconditions:

- For the overloads with no `ExecutionPolicy`, *T* meets the *Cpp17MoveAssignable* (Table 33) requirements.
- For all overloads, in the ranges `[first, last]` and `[result, result + (last - first)]`, `binary_op` neither modifies elements nor invalidates iterators or subranges.²²³

Effects: For the overloads with no `ExecutionPolicy` and a non-empty range, the function creates an accumulator `acc` of type *T*, initializes it with `*first`, and assigns the result to `*result`. For every iterator *i* in `[first + 1, last)` in order, creates an object `val` whose type is *T*, initializes it with `*i`, computes `binary_op(val, std::move(acc))`, assigns the result to `*(result + (i - first))`, and move assigns from `val` to `acc`.

For the overloads with an `ExecutionPolicy` and a non-empty range, performs `*result = *first`. Then, for every *d* in `[1, last - first - 1]`, performs `*(result + d) = binary_op(*(first + d), *(first + (d - 1)))`.

Returns: `result + (last - first)`.

Complexity: Exactly `(last - first) - 1` applications of the binary operation.

Remarks: For the overloads with no `ExecutionPolicy`, `result` may be equal to `first`. For the overloads with an `ExecutionPolicy`, the ranges `[first, last)` and `[result, result + (last - first))` shall not overlap.

27.10.13 Iota

[numeric.iota]

```
template<class ForwardIterator, class T>
constexpr void iota(ForwardIterator first, ForwardIterator last, T value);
```

Mandates: *T* is convertible to `ForwardIterator`'s value type. The expression `++val`, where `val` has type *T*, is well-formed.

Effects: For each element referred to by the iterator *i* in the range `[first, last)`, assigns `*i = value` and increments `value` as if by `++value`.

Complexity: Exactly `last - first` increments and assignments.

```
template<input_or_output_iterator O, sentinel_for<O> S, weakly_incrementable T>
requires indirectly_writable<O, const T&>
constexpr ranges::iota_result<O, T> ranges::iota(O first, S last, T value);
template<weakly_incrementable T, output_range<const T&> R>
constexpr ranges::iota_result<borrowed_iterator_t<R>, T> ranges::iota(R&& r, T value);
```

Effects: Equivalent to:

```
while (first != last) {
    *first = as_const(value);
    ++first;
```

²²³) The use of fully closed ranges is intentional.

```

    ++value;
}
return {std::move(first), std::move(value)};

```

27.10.14 Greatest common divisor

[numeric.ops.gcd]

```

template<class M, class N>
constexpr common_type_t<M, N> gcd(M m, N n);

```

Mandates: M and N both are integer types other than *cv bool*.

Preconditions: $|m|$ and $|n|$ are representable as a value of `common_type_t<M, N>`.

NOTE These requirements ensure, for example, that `gcd(m, m) = |m|` is representable as a value of type M.

Returns: Zero when `m` and `n` are both zero. Otherwise, returns the greatest common divisor of $|m|$ and $|n|$.

Throws: Nothing.

27.10.15 Least common multiple

[numeric.ops.lcm]

```

template<class M, class N>
constexpr common_type_t<M, N> lcm(M m, N n);

```

Mandates: M and N both are integer types other than *cv bool*.

Preconditions: $|m|$ and $|n|$ are representable as a value of `common_type_t<M, N>`. The least common multiple of $|m|$ and $|n|$ is representable as a value of type `common_type_t<M, N>`.

Returns: Zero when either `m` or `n` is zero. Otherwise, returns the least common multiple of $|m|$ and $|n|$.

Throws: Nothing.

27.10.16 Midpoint

[numeric.ops.midpoint]

```

template<class T>
constexpr T midpoint(T a, T b) noexcept;

```

Constraints: T is an arithmetic type other than *bool*.

Returns: Half the sum of `a` and `b`. If T is an integer type and the sum is odd, the result is rounded towards `a`.

Remarks: No overflow occurs. If T is a floating-point type, at most one inexact operation occurs.

```

template<class T>
constexpr T* midpoint(T* a, T* b);

```

Constraints: T is an object type.

Mandates: T is a complete type.

Preconditions: `a` and `b` point to, respectively, elements *i* and *j* of the same array object `x`.

NOTE As specified in 6.8.4, an object that is not an array element is considered to belong to a single-element array for this purpose and a pointer past the last element of an array of *n* elements is considered to be equivalent to a pointer to a hypothetical array element *n* for this purpose.

Returns: A pointer to array element $i + \frac{j-i}{2}$ of `x`, where the result of the division is truncated towards zero.

27.11 Specialized <memory> algorithms

[specialized.algorithms]

27.11.1 General

[specialized.algorithms.general]

The contents specified in 27.11 are declared in the header `<memory>` (20.2.2).

Unless otherwise specified, if an exception is thrown in the following algorithms, objects constructed by a placement *new-expression* (7.6.2.8) are destroyed in an unspecified order before allowing the exception to propagate.

Some algorithms specified in 27.11 make use of the exposition-only function `voidify`:

```
template<class T>
constexpr void* voidify(T& obj) noexcept {
    return addressof(obj);
}
```

27.11.2 Special memory concepts

[special.mem.concepts]

Some algorithms in this subclause are constrained with the following exposition-only concepts:

```
template<class I>
concept nothrow-input-iterator = // exposition only
    input_iterator<I> &&
    is_lvalue_reference_v<iter_reference_t<I>> &&
    same_as<remove_cvref_t<iter_reference_t<I>>, iter_value_t<I>>;
```

A type *I* models *nothrow-input-iterator* only if no exceptions are thrown from increment, copy construction, move construction, copy assignment, move assignment, or indirection through valid iterators.

NOTE 1 This concept allows some *input_iterator* (25.3.4.9) operations to throw exceptions.

```
template<class S, class I>
concept nothrow-sentinel-for = sentinel_for<S, I>; // exposition only
```

Types *S* and *I* model *nothrow-sentinel-for* only if no exceptions are thrown from copy construction, move construction, copy assignment, move assignment, or comparisons between valid values of type *I* and *S*.

NOTE 2 This concept allows some *sentinel_for* (25.3.4.7) operations to throw exceptions.

```
template<class R>
concept nothrow-input-range = // exposition only
    range<R> &&
    nothrow-input-iterator<iterator_t<R>> &&
    nothrow-sentinel-for<sentinel_t<R>, iterator_t<R>>;
```

A type *R* models *nothrow-input-range* only if no exceptions are thrown from calls to *ranges::begin* and *ranges::end* on an object of type *R*.

```
template<class I>
concept nothrow-forward-iterator = // exposition only
    nothrow-input-iterator<I> &&
    forward_iterator<I> &&
    nothrow-sentinel-for<I, I>;
```

NOTE 3 This concept allows some *forward_iterator* (25.3.4.11) operations to throw exceptions.

```
template<class R>
concept nothrow-forward-range = // exposition only
    nothrow-input-range<R> &&
    nothrow-forward-iterator<iterator_t<R>>;
```

27.11.3 uninitialized_default_construct

[uninitialized.construct.default]

```
template<class NoThrowForwardIterator>
void uninitialized_default_construct(NoThrowForwardIterator first, NoThrowForwardIterator last);
```

Effects: Equivalent to:

```
for (; first != last; ++first)
    ::new (voidify(*first))
        typename iterator_traits<NoThrowForwardIterator>::value_type;
```

```
namespace ranges {
    template<nothrow-forward-iterator I, nothrow-sentinel-for<I> S>
    requires default_initializable<iter_value_t<I>>
    I uninitialized_default_construct(I first, S last);
}
```

```
template<nothrow-forward-range R>
  requires default_initializable<range_value_t<R>>
  borrowed_iterator_t<R> uninitialized_default_construct(R&& r);
}
```

Effects: Equivalent to:

```
for (; first != last; ++first)
  ::new (voidify(*first)) remove_reference_t<iter_reference_t<I>>;
return first;
```

```
template<class NoThrowForwardIterator, class Size>
  NoThrowForwardIterator uninitialized_default_construct_n(NoThrowForwardIterator first, Size n);
```

Effects: Equivalent to:

```
for (; n > 0; (void)++first, --n)
  ::new (voidify(*first))
    typename iterator_traits<NoThrowForwardIterator>::value_type;
return first;
```

```
namespace ranges {
  template<nothrow-forward-iterator I>
    requires default_initializable<iter_value_t<I>>
    I uninitialized_default_construct_n(I first, iter_difference_t<I> n);
}
```

Effects: Equivalent to:

```
return uninitialized_default_construct(counted_iterator(first, n),
                                     default_sentinel).base();
```

27.11.4 uninitialized_value_construct [uninitialized.construct.value]

```
template<class NoThrowForwardIterator>
  void uninitialized_value_construct(NoThrowForwardIterator first, NoThrowForwardIterator last);
```

Effects: Equivalent to:

```
for (; first != last; ++first)
  ::new (voidify(*first))
    typename iterator_traits<NoThrowForwardIterator>::value_type();
```

```
namespace ranges {
  template<nothrow-forward-iterator I, nothrow-sentinel-for<I> S>
    requires default_initializable<iter_value_t<I>>
    I uninitialized_value_construct(I first, S last);
  template<nothrow-forward-range R>
    requires default_initializable<range_value_t<R>>
    borrowed_iterator_t<R> uninitialized_value_construct(R&& r);
}
```

Effects: Equivalent to:

```
for (; first != last; ++first)
  ::new (voidify(*first)) remove_reference_t<iter_reference_t<I>>();
return first;
```

```
template<class NoThrowForwardIterator, class Size>
  NoThrowForwardIterator uninitialized_value_construct_n(NoThrowForwardIterator first, Size n);
```

Effects: Equivalent to:

```
for (; n > 0; (void)++first, --n)
  ::new (voidify(*first))
    typename iterator_traits<NoThrowForwardIterator>::value_type();
return first;
```

```
namespace ranges {
  template<nothrow-forward-iterator I>
    requires default_initializable<iter_value_t<I>>
    I uninitialized_value_construct_n(I first, iter_difference_t<I> n);
}
```

}

Effects: Equivalent to:

```
return uninitialized_value_construct(counted_iterator(first, n),
                                   default_sentinel).base();
```

27.11.5 uninitialized_copy**[uninitialized.copy]**

```
template<class InputIterator, class NoThrowForwardIterator>
NoThrowForwardIterator uninitialized_copy(InputIterator first, InputIterator last,
                                       NoThrowForwardIterator result);
```

Preconditions: $\text{result} + [0, (\text{last} - \text{first}))$ does not overlap with $[\text{first}, \text{last})$.*Effects:* Equivalent to:

```
for (; first != last; ++result, (void) ++first)
    ::new (voidify(*result))
        typename iterator_traits<NoThrowForwardIterator>::value_type(*first);
```

Returns: result.

```
namespace ranges {
template<input_iterator I, sentinel_for<I> S1,
        nothrow_forward_iterator O, nothrow_sentinel_for<O> S2>
requires constructible_from<iter_value_t<O>, iter_reference_t<I>>
uninitialized_copy_result<I, O>
    uninitialized_copy(I ifirst, S1 ilast, O ofirst, S2 olast);
template<input_range IR, nothrow_forward_range OR>
requires constructible_from<range_value_t<OR>, range_reference_t<IR>>
uninitialized_copy_result<borrowed_iterator_t<IR>, borrowed_iterator_t<OR>>
    uninitialized_copy(IR&& in_range, OR&& out_range);
}
```

Preconditions: $[\text{ofirst}, \text{olast})$ does not overlap with $[\text{ifirst}, \text{ilast})$.*Effects:* Equivalent to:

```
for (; ifirst != ilast && ofirst != olast; ++ofirst, (void)++ifirst)
    ::new (voidify(*ofirst)) remove_reference_t<iter_reference_t<O>>(*ifirst);
return {std::move(ifirst), ofirst};
```

```
template<class InputIterator, class Size, class NoThrowForwardIterator>
NoThrowForwardIterator uninitialized_copy_n(InputIterator first, Size n,
                                       NoThrowForwardIterator result);
```

Preconditions: $\text{result} + [0, n)$ does not overlap with $\text{first} + [0, n)$.*Effects:* Equivalent to:

```
for (; n > 0; ++result, (void) ++first, --n)
    ::new (voidify(*result))
        typename iterator_traits<NoThrowForwardIterator>::value_type(*first);
```

Returns: result.

```
namespace ranges {
template<input_iterator I, nothrow_forward_iterator O, nothrow_sentinel_for<O> S>
requires constructible_from<iter_value_t<O>, iter_reference_t<I>>
uninitialized_copy_n_result<I, O>
    uninitialized_copy_n(I ifirst, iter_difference_t<I> n, O ofirst, S olast);
}
```

Preconditions: $[\text{ofirst}, \text{olast})$ does not overlap with $\text{ifirst} + [0, n)$.*Effects:* Equivalent to:

```
auto t = uninitialized_copy(counted_iterator(std::move(ifirst), n),
                           default_sentinel, ofirst, olast);
return {std::move(t.in).base(), t.out};
```

27.11.6 uninitialized_move

[uninitialized.move]

```
template<class InputIterator, class NoThrowForwardIterator>
NoThrowForwardIterator uninitialized_move(InputIterator first, InputIterator last,
                                         NoThrowForwardIterator result);
```

Preconditions: result + [0, (last - first)) does not overlap with [first, last).

Effects: Equivalent to:

```
for (; first != last; (void)++result, ++first)
    ::new (voidify(*result))
        typename iterator_traits<NoThrowForwardIterator>::value_type(std::move(*first));
return result;
```

```
namespace ranges {
template<input_iterator I, sentinel_for<I> S1,
        nothrow_forward_iterator O, nothrow_sentinel_for<O> S2>
requires constructible_from<iter_value_t<O>, iter_rvalue_reference_t<I>>
uninitialized_move_result<I, O>
    uninitialized_move(I ifirst, S1 ilast, O ofirst, S2 olast);
template<input_range IR, nothrow_forward_range OR>
requires constructible_from<range_value_t<OR>, range_rvalue_reference_t<IR>>
uninitialized_move_result<borrowed_iterator_t<IR>, borrowed_iterator_t<OR>>
    uninitialized_move(IR&& in_range, OR&& out_range);
}
```

Preconditions: [ofirst, olast) does not overlap with [ifirst, ilast).

Effects: Equivalent to:

```
for (; ifirst != ilast && ofirst != olast; ++ofirst, (void)++ifirst)
    ::new (voidify(*ofirst))
        remove_reference_t<iter_reference_t<O>>(ranges::iter_move(ifirst));
return {std::move(ifirst), ofirst};
```

NOTE 1 If an exception is thrown, some objects in the range [ifirst, ilast) are left in a valid, but unspecified state.

```
template<class InputIterator, class Size, class NoThrowForwardIterator>
pair<InputIterator, NoThrowForwardIterator>
uninitialized_move_n(InputIterator first, Size n, NoThrowForwardIterator result);
```

Preconditions: result + [0, n) does not overlap with first + [0, n).

Effects: Equivalent to:

```
for (; n > 0; ++result, (void) ++first, --n)
    ::new (voidify(*result))
        typename iterator_traits<NoThrowForwardIterator>::value_type(std::move(*first));
return {first, result};
```

```
namespace ranges {
template<input_iterator I, nothrow_forward_iterator O, nothrow_sentinel_for<O> S>
requires constructible_from<iter_value_t<O>, iter_rvalue_reference_t<I>>
uninitialized_move_n_result<I, O>
    uninitialized_move_n(I ifirst, iter_difference_t<I> n, O ofirst, S olast);
}
```

Preconditions: [ofirst, olast) does not overlap with ifirst + [0, n).

Effects: Equivalent to:

```
auto t = uninitialized_move(counted_iterator(std::move(ifirst), n),
                                     default_sentinel, ofirst, olast);
return {std::move(t.in).base(), t.out};
```

NOTE 2 If an exception is thrown, some objects in the range ifirst + [0, n) are left in a valid but unspecified state.

27.11.7 uninitialized_fill**[uninitialized.fill]**

```
template<class NoThrowForwardIterator, class T>
void uninitialized_fill(NoThrowForwardIterator first, NoThrowForwardIterator last, const T& x);
```

Effects: Equivalent to:

```
for (; first != last; ++first)
    ::new (voidify(*first))
        typename iterator_traits<NoThrowForwardIterator>::value_type(x);
```

```
namespace ranges {
    template<nothrow-forward-iterator I, nothrow-sentinel-for<I> S, class T>
        requires constructible_from<iter_value_t<I>, const T&>
        I uninitialized_fill(I first, S last, const T& x);
    template<nothrow-forward-range R, class T>
        requires constructible_from<range_value_t<R>, const T&>
        borrowed_iterator_t<R> uninitialized_fill(R&& r, const T& x);
}
```

Effects: Equivalent to:

```
for (; first != last; ++first)
    ::new (voidify(*first)) remove_reference_t<iter_reference_t<I>>(x);
return first;
```

```
template<class NoThrowForwardIterator, class Size, class T>
NoThrowForwardIterator uninitialized_fill_n(NoThrowForwardIterator first, Size n, const T& x);
```

Effects: Equivalent to:

```
for (; n--; ++first)
    ::new (voidify(*first))
        typename iterator_traits<NoThrowForwardIterator>::value_type(x);
return first;
```

```
namespace ranges {
    template<nothrow-forward-iterator I, class T>
        requires constructible_from<iter_value_t<I>, const T&>
        I uninitialized_fill_n(I first, iter_difference_t<I> n, const T& x);
}
```

Effects: Equivalent to:

```
return uninitialized_fill(counted_iterator(first, n), default_sentinel, x).base();
```

27.11.8 construct_at**[specialized.construct]**

```
template<class T, class... Args>
constexpr T* construct_at(T* location, Args&&... args);
```

```
namespace ranges {
    template<class T, class... Args>
        constexpr T* construct_at(T* location, Args&&... args);
}
```

Constraints: The expression `::new (declval<void*>()) T(declval<Args>())...` is well-formed when treated as an unevaluated operand (7.2.3).

Effects: Equivalent to:

```
return ::new (voidify(*location)) T(std::forward<Args>(args)...);
```

27.11.9 destroy**[specialized.destroy]**

```
template<class T>
constexpr void destroy_at(T* location);
namespace ranges {
    template<destructible T>
        constexpr void destroy_at(T* location) noexcept;
```

}

Effects:

- If T is an array type, equivalent to `destroy(begin(*location), end(*location))`.
- Otherwise, equivalent to `location->~T()`.

```
template<class NoThrowForwardIterator>
constexpr void destroy(NoThrowForwardIterator first, NoThrowForwardIterator last);
```

Effects: Equivalent to:

```
for (; first != last; ++first)
    destroy_at(addressof(*first));
```

```
namespace ranges {
    template<nothrow-input-iterator I, nothrow-sentinel-for<I> S>
        requires destructible<iter_value_t<I>>
        constexpr I destroy(I first, S last) noexcept;
    template<nothrow-input-range R>
        requires destructible<range_value_t<R>>
        constexpr borrowed_iterator_t<R> destroy(R&& r) noexcept;
}
```

Effects: Equivalent to:

```
for (; first != last; ++first)
    destroy_at(addressof(*first));
return first;
```

```
template<class NoThrowForwardIterator, class Size>
constexpr NoThrowForwardIterator destroy_n(NoThrowForwardIterator first, Size n);
```

Effects: Equivalent to:

```
for (; n > 0; (void)++first, --n)
    destroy_at(addressof(*first));
return first;
```

```
namespace ranges {
    template<nothrow-input-iterator I>
        requires destructible<iter_value_t<I>>
        constexpr I destroy_n(I first, iter_difference_t<I> n) noexcept;
}
```

Effects: Equivalent to:

```
return destroy(counted_iterator(std::move(first), n), default_sentinel).base();
```

27.12 C library algorithms

[alg.c.library]

NOTE The header `<cstdlib>` (17.2.2) declares the functions described in this subclause.

```
void* bsearch(const void* key, const void* base, size_t nmemb, size_t size,
    c-compare-pred* compar);
void* bsearch(const void* key, const void* base, size_t nmemb, size_t size,
    compare-pred* compar);
void qsort(void* base, size_t nmemb, size_t size, c-compare-pred* compar);
void qsort(void* base, size_t nmemb, size_t size, compare-pred* compar);
```

Preconditions: For `qsort`, the objects in the array pointed to by `base` are of trivially copyable type.

Effects: These functions have the semantics specified in the C standard library.

Throws: Any exception thrown by `compar` (16.4.6.13).

See also ISO/IEC 9899:2018, 7.22.5.

28 Numerics library

[numerics]

28.1 General

[numerics.general]

This Clause describes components that C++ programs may use to perform seminumerical operations.

The following subclauses describe components for complex number types, random number generation, numeric (*n*-at-a-time) arrays, generalized numeric algorithms, and mathematical constants and functions for floating-point types, as summarized in Table 94.

Table 94 — Numerics library summary [tab:numerics.summary]

Subclause	Header
28.2 Requirements	
28.3 Floating-point environment	<cfenv>
28.4 Complex numbers	<complex>
28.5 Random number generation	<random>
28.6 Numeric arrays	<valarray>
28.7 Mathematical functions for floating-point types	<cmath>, <cstdlib>
28.8 Numbers	<numbers>

28.2 Numeric type requirements

[numeric.requirements]

The `complex` and `valarray` components are parameterized by the type of information they contain and manipulate. A C++ program shall instantiate these components only with a numeric type. A *numeric type* is a cv-unqualified object type *T* that meets the *Cpp17DefaultConstructible*, *Cpp17CopyConstructible*, *Cpp17CopyAssignable*, and *Cpp17Destructible* requirements (16.4.4.2).²²⁴

If any operation on *T* throws an exception the effects are undefined.

In addition, many member and related functions of `valarray<T>` can be successfully instantiated and will exhibit well-defined behavior if and only if *T* meets additional requirements specified for each such member or related function.

EXAMPLE It is valid to instantiate `valarray<complex>`, but `operator>()` will not be successfully instantiated for `valarray<complex>` operands, since `complex` does not have any ordering operators.

28.3 The floating-point environment

[cfenv]

28.3.1 Header <cfenv> synopsis

[cfenv.syn]

```
#define FE_ALL_EXCEPT see below
#define FE_DIVBYZERO see below    // optional
#define FE_INEXACT see below      // optional
#define FE_INVALID see below      // optional
#define FE_OVERFLOW see below     // optional
#define FE_UNDERFLOW see below    // optional

#define FE_DOWNWARD see below     // optional
#define FE_TONEAREST see below    // optional
#define FE_TOWARDZERO see below   // optional
#define FE_UPWARD see below       // optional

#define FE_DFL_ENV see below

namespace std {
    // types
    using fenv_t    = object type;
    using fexcept_t = integer type;
```

²²⁴) In other words, value types. These include arithmetic types, pointers, the library class `complex`, and instantiations of `valarray` for value types.

```

// functions
int feclearexcept(int except);
int fegetexceptflag(fexcept_t* pflag, int except);
int feraiseexcept(int except);
int fesetexceptflag(const fexcept_t* pflag, int except);
int fetestexcept(int except);

int fegetround();
int fesetround(int mode);

int fegetenv(fenv_t* penv);
int feholdexcept(fenv_t* penv);
int fesetenv(const fenv_t* penv);
int feupdateenv(const fenv_t* penv);
}

```

The contents and meaning of the header `<cfenv>` are the same as the C standard library header `<fenv.h>`.

NOTE This document does not require an implementation to support the `FENV_ACCESS` pragma; it is implementation-defined (15.9) whether the pragma is supported. As a consequence, it is implementation-defined whether these functions can be used to test floating-point status flags, set floating-point control modes, or run under non-default mode settings. If the pragma is used to enable control over the floating-point environment, this document does not specify the effect on floating-point evaluation in constant expressions.

See also ISO/IEC 9899:2018, 7.6.

28.3.2 Threads

[cfenv.thread]

The floating-point environment has thread storage duration (6.7.5.3). The initial state for a thread's floating-point environment is the state of the floating-point environment of the thread that constructs the corresponding `thread` object (33.4.3) or `jthread` object (33.4.4) at the time it constructed the object.

NOTE That is, the child thread gets the floating-point state of the parent thread at the time of the child's creation.

A separate floating-point environment is maintained for each thread. Each function accesses the environment corresponding to its calling thread.

28.4 Complex numbers

[complex.numbers]

28.4.1 General

[complex.numbers.general]

The header `<complex>` defines a class template, and numerous functions for representing and manipulating complex numbers.

The effect of instantiating the template `complex` for any type that is not a cv-unqualified floating-point type (6.8.2) is unspecified. Specializations of `complex` for cv-unqualified floating-point types are trivially-copyable literal types (6.8.1).

If the result of a function is not mathematically defined or not in the range of representable values for its type, the behavior is undefined.

If `z` is an lvalue of type `cv complex<T>` then:

- the expression `reinterpret_cast<cv T(&)[2]>(z)` is well-formed,
- `reinterpret_cast<cv T(&)[2]>(z)[0]` designates the real part of `z`, and
- `reinterpret_cast<cv T(&)[2]>(z)[1]` designates the imaginary part of `z`.

Moreover, if `a` is an expression of type `cv complex<T>*` and the expression `a[i]` is well-defined for an integer expression `i`, then:

- `reinterpret_cast<cv T*>(a)[2*i]` designates the real part of `a[i]`, and
- `reinterpret_cast<cv T*>(a)[2*i + 1]` designates the imaginary part of `a[i]`.

28.4.2 Header `<complex>` synopsis

[complex.syn]

```

namespace std {
    // 28.4.3, class template complex
    template<class T> class complex;
}

```

// 28.4.6, operators

```
template<class T> constexpr complex<T> operator+(const complex<T>&, const complex<T>&);
template<class T> constexpr complex<T> operator+(const complex<T>&, const T&);
template<class T> constexpr complex<T> operator+(const T&, const complex<T>&);

template<class T> constexpr complex<T> operator-(const complex<T>&, const complex<T>&);
template<class T> constexpr complex<T> operator-(const complex<T>&, const T&);
template<class T> constexpr complex<T> operator-(const T&, const complex<T>&);

template<class T> constexpr complex<T> operator*(const complex<T>&, const complex<T>&);
template<class T> constexpr complex<T> operator*(const complex<T>&, const T&);
template<class T> constexpr complex<T> operator*(const T&, const complex<T>&);

template<class T> constexpr complex<T> operator/(const complex<T>&, const complex<T>&);
template<class T> constexpr complex<T> operator/(const complex<T>&, const T&);
template<class T> constexpr complex<T> operator/(const T&, const complex<T>&);

template<class T> constexpr complex<T> operator+(const complex<T>&);
template<class T> constexpr complex<T> operator-(const complex<T>&);

template<class T> constexpr bool operator==(const complex<T>&, const complex<T>&);
template<class T> constexpr bool operator==(const complex<T>&, const T&);

template<class T, class charT, class traits>
    basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>&, complex<T>&);

template<class T, class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>&, const complex<T>&);
```

// 28.4.7, values

```
template<class T> constexpr T real(const complex<T>&);
template<class T> constexpr T imag(const complex<T>&);

template<class T> T abs(const complex<T>&);
template<class T> T arg(const complex<T>&);
template<class T> constexpr T norm(const complex<T>&);

template<class T> constexpr complex<T> conj(const complex<T>&);
template<class T> complex<T> proj(const complex<T>&);
template<class T> complex<T> polar(const T&, const T& = T());
```

// 28.4.8, transcendentals

```
template<class T> complex<T> acos(const complex<T>&);
template<class T> complex<T> asin(const complex<T>&);
template<class T> complex<T> atan(const complex<T>&);

template<class T> complex<T> acosh(const complex<T>&);
template<class T> complex<T> asinh(const complex<T>&);
template<class T> complex<T> atanh(const complex<T>&);

template<class T> complex<T> cos (const complex<T>&);
template<class T> complex<T> cosh (const complex<T>&);
template<class T> complex<T> exp (const complex<T>&);
template<class T> complex<T> log (const complex<T>&);
template<class T> complex<T> log10(const complex<T>&);

template<class T> complex<T> pow (const complex<T>&, const T&);
template<class T> complex<T> pow (const complex<T>&, const complex<T>&);
template<class T> complex<T> pow (const T&, const complex<T>&);

template<class T> complex<T> sin (const complex<T>&);
template<class T> complex<T> sinh (const complex<T>&);
template<class T> complex<T> sqrt (const complex<T>&);
template<class T> complex<T> tan (const complex<T>&);
```

```

template<class T> complex<T> tanh (const complex<T>&);

// 28.4.10, complex literals
inline namespace literals {
inline namespace complex_literals {
    constexpr complex<long double> operator""il(long double);
    constexpr complex<long double> operator""il(unsigned long long);
    constexpr complex<double> operator""i(long double);
    constexpr complex<double> operator""i(unsigned long long);
    constexpr complex<float> operator""if(long double);
    constexpr complex<float> operator""if(unsigned long long);
}
}
}

```

28.4.3 Class template complex

[complex]

```

namespace std {
    template<class T> class complex {
    public:
        using value_type = T;

        constexpr complex(const T& re = T(), const T& im = T());
        constexpr complex(const complex&) = default;
        template<class X> constexpr explicit(see below) complex(const complex<X>&);

        constexpr T real() const;
        constexpr void real(T);
        constexpr T imag() const;
        constexpr void imag(T);

        constexpr complex& operator= (const T&);
        constexpr complex& operator+=(const T&);
        constexpr complex& operator-=(const T&);
        constexpr complex& operator*=(const T&);
        constexpr complex& operator/=(const T&);

        constexpr complex& operator=(const complex&);
        template<class X> constexpr complex& operator= (const complex<X>&);
        template<class X> constexpr complex& operator+=(const complex<X>&);
        template<class X> constexpr complex& operator-=(const complex<X>&);
        template<class X> constexpr complex& operator*=(const complex<X>&);
        template<class X> constexpr complex& operator/=(const complex<X>&);
    };
}

```

The class `complex` describes an object that can store the Cartesian components, `real()` and `imag()`, of a complex number.

28.4.4 Member functions

[complex.members]

```
constexpr complex(const T& re = T(), const T& im = T());
```

Postconditions: `real() == re && imag() == im` is true.

```
template<class X> constexpr explicit(see below) complex(const complex<X>& other);
```

Effects: Initializes the real part with `other.real()` and the imaginary part with `other.imag()`.

Remarks: The expression inside `explicit` evaluates to `false` if and only if the floating-point conversion rank of `T` is greater than or equal to the floating-point conversion rank of `X`.

```
constexpr T real() const;
```

Returns: The value of the real component.

```
constexpr void real(T val);
```

Effects: Assigns `val` to the real component.

```
constexpr T imag() const;
```

Returns: The value of the imaginary component.

```
constexpr void imag(T val);
```

Effects: Assigns `val` to the imaginary component.

28.4.5 Member operators

[complex.member.ops]

```
constexpr complex& operator+=(const T& rhs);
```

Effects: Adds the scalar value `rhs` to the real part of the complex value `*this` and stores the result in the real part of `*this`, leaving the imaginary part unchanged.

Returns: `*this`.

```
constexpr complex& operator-=(const T& rhs);
```

Effects: Subtracts the scalar value `rhs` from the real part of the complex value `*this` and stores the result in the real part of `*this`, leaving the imaginary part unchanged.

Returns: `*this`.

```
constexpr complex& operator*=(const T& rhs);
```

Effects: Multiplies the scalar value `rhs` by the complex value `*this` and stores the result in `*this`.

Returns: `*this`.

```
constexpr complex& operator/=(const T& rhs);
```

Effects: Divides the scalar value `rhs` into the complex value `*this` and stores the result in `*this`.

Returns: `*this`.

```
template<class X> constexpr complex& operator+=(const complex<X>& rhs);
```

Effects: Adds the complex value `rhs` to the complex value `*this` and stores the sum in `*this`.

Returns: `*this`.

```
template<class X> constexpr complex& operator-=(const complex<X>& rhs);
```

Effects: Subtracts the complex value `rhs` from the complex value `*this` and stores the difference in `*this`.

Returns: `*this`.

```
template<class X> constexpr complex& operator*=(const complex<X>& rhs);
```

Effects: Multiplies the complex value `rhs` by the complex value `*this` and stores the product in `*this`.

Returns: `*this`.

```
template<class X> constexpr complex& operator/=(const complex<X>& rhs);
```

Effects: Divides the complex value `rhs` into the complex value `*this` and stores the quotient in `*this`.

Returns: `*this`.

28.4.6 Non-member operations

[complex.ops]

```
template<class T> constexpr complex<T> operator+(const complex<T>& lhs);
```

Returns: `complex<T>(lhs)`.

```
template<class T> constexpr complex<T> operator+(const complex<T>& lhs, const complex<T>& rhs);
```

```
template<class T> constexpr complex<T> operator+(const complex<T>& lhs, const T& rhs);
```

```
template<class T> constexpr complex<T> operator+(const T& lhs, const complex<T>& rhs);
```

Returns: `complex<T>(lhs) += rhs`.

```
template<class T> constexpr complex<T> operator-(const complex<T>& lhs);
```

Returns: `complex<T>(-lhs.real(), -lhs.imag())`.

```
template<class T> constexpr complex<T> operator-(const complex<T>& lhs, const complex<T>& rhs);
template<class T> constexpr complex<T> operator-(const complex<T>& lhs, const T& rhs);
template<class T> constexpr complex<T> operator-(const T& lhs, const complex<T>& rhs);
```

Returns: `complex<T>(lhs) -= rhs`.

```
template<class T> constexpr complex<T> operator*(const complex<T>& lhs, const complex<T>& rhs);
template<class T> constexpr complex<T> operator*(const complex<T>& lhs, const T& rhs);
template<class T> constexpr complex<T> operator*(const T& lhs, const complex<T>& rhs);
```

Returns: `complex<T>(lhs) *= rhs`.

```
template<class T> constexpr complex<T> operator/(const complex<T>& lhs, const complex<T>& rhs);
template<class T> constexpr complex<T> operator/(const complex<T>& lhs, const T& rhs);
template<class T> constexpr complex<T> operator/(const T& lhs, const complex<T>& rhs);
```

Returns: `complex<T>(lhs) /= rhs`.

```
template<class T> constexpr bool operator==(const complex<T>& lhs, const complex<T>& rhs);
template<class T> constexpr bool operator==(const complex<T>& lhs, const T& rhs);
```

Returns: `lhs.real() == rhs.real() && lhs.imag() == rhs.imag()`.

Remarks: The imaginary part is assumed to be `T()`, or 0.0, for the `T` arguments.

```
template<class T, class charT, class traits>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, complex<T>& x);
```

Preconditions: The input values are convertible to `T`.

Effects: Extracts a complex number `x` of the form: `u`, `(u)`, or `(u,v)`, where `u` is the real part and `v` is the imaginary part (31.7.5.3).

If bad input is encountered, calls `is.setstate(ios_base::failbit)` (which may throw `ios_base::failure` (31.5.4.4)).

Returns: `is`.

Remarks: This extraction is performed as a series of simpler extractions. Therefore, the skipping of whitespace is specified to be the same for each of the simpler extractions.

```
template<class T, class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& o, const complex<T>& x);
```

Effects: Inserts the complex number `x` onto the stream `o` as if it were implemented as follows:

```
basic_ostringstream<charT, traits> s;
s.flags(o.flags());
s.imbue(o.getloc());
s.precision(o.precision());
s << '(' << x.real() << ',' << x.imag() << ')';
return o << s.str();
```

NOTE In a locale in which comma is used as a decimal point character, the use of comma as a field separator can be ambiguous. Inserting `showpoint` into the output stream forces all outputs to show an explicit decimal point character; as a result, all inserted sequences of complex numbers can be extracted unambiguously.

28.4.7 Value operations

[complex.value.ops]

```
template<class T> constexpr T real(const complex<T>& x);
```

Returns: `x.real()`.

```
template<class T> constexpr T imag(const complex<T>& x);
```

Returns: `x.imag()`.

```
template<class T> T abs(const complex<T>& x);
```

Returns: The magnitude of `x`.

```
template<class T> T arg(const complex<T>& x);
```

Returns: The phase angle of x , or $\text{atan2}(\text{imag}(x), \text{real}(x))$.

```
template<class T> constexpr T norm(const complex<T>& x);
```

Returns: The squared magnitude of x .

```
template<class T> constexpr complex<T> conj(const complex<T>& x);
```

Returns: The complex conjugate of x .

```
template<class T> complex<T> proj(const complex<T>& x);
```

Returns: The projection of x onto the Riemann sphere.

Remarks: Behaves the same as the C function `cproj`. See also ISO/IEC 9899:2018, 7.3.9.5.

```
template<class T> complex<T> polar(const T& rho, const T& theta = T());
```

Preconditions: rho is non-negative and non-NaN. theta is finite.

Returns: The complex value corresponding to a complex number whose magnitude is rho and whose phase angle is theta .

28.4.8 Transcendentals

[`complex.transcendentals`]

```
template<class T> complex<T> acos(const complex<T>& x);
```

Returns: The complex arc cosine of x .

Remarks: Behaves the same as the C function `cacos`. See also ISO/IEC 9899:2018, 7.3.5.1.

```
template<class T> complex<T> asin(const complex<T>& x);
```

Returns: The complex arc sine of x .

Remarks: Behaves the same as the C function `casin`. See also ISO/IEC 9899:2018, 7.3.5.2.

```
template<class T> complex<T> atan(const complex<T>& x);
```

Returns: The complex arc tangent of x .

Remarks: Behaves the same as the C function `catan`. See also ISO/IEC 9899:2018, 7.3.5.3.

```
template<class T> complex<T> acosh(const complex<T>& x);
```

Returns: The complex arc hyperbolic cosine of x .

Remarks: Behaves the same as the C function `cacosh`. See also ISO/IEC 9899:2018, 7.3.6.1.

```
template<class T> complex<T> asinh(const complex<T>& x);
```

Returns: The complex arc hyperbolic sine of x .

Remarks: Behaves the same as the C function `casinh`. See also ISO/IEC 9899:2018, 7.3.6.2.

```
template<class T> complex<T> atanh(const complex<T>& x);
```

Returns: The complex arc hyperbolic tangent of x .

Remarks: Behaves the same as the C function `catanh`. See also ISO/IEC 9899:2018, 7.3.6.3.

```
template<class T> complex<T> cos(const complex<T>& x);
```

Returns: The complex cosine of x .

```
template<class T> complex<T> cosh(const complex<T>& x);
```

Returns: The complex hyperbolic cosine of x .

```
template<class T> complex<T> exp(const complex<T>& x);
```

Returns: The complex base- e exponential of x .

```
template<class T> complex<T> log(const complex<T>& x);
```

Returns: The complex natural (base- e) logarithm of x . For all x , $\text{imag}(\log(x))$ lies in the interval $[-\pi, \pi]$.

NOTE 1 The semantics of this function are intended to be the same in C++ as they are for `clog` in C.

Remarks: The branch cuts are along the negative real axis.

```
template<class T> complex<T> log10(const complex<T>& x);
```

Returns: The complex common (base-10) logarithm of `x`, defined as $\log(x) / \log(10)$.

Remarks: The branch cuts are along the negative real axis.

```
template<class T> complex<T> pow(const complex<T>& x, const complex<T>& y);
```

```
template<class T> complex<T> pow(const complex<T>& x, const T& y);
```

```
template<class T> complex<T> pow(const T& x, const complex<T>& y);
```

Returns: The complex power of base `x` raised to the y^{th} power, defined as $\exp(y * \log(x))$. The value returned for `pow(0, 0)` is implementation-defined.

Remarks: The branch cuts are along the negative real axis.

```
template<class T> complex<T> sin(const complex<T>& x);
```

Returns: The complex sine of `x`.

```
template<class T> complex<T> sinh(const complex<T>& x);
```

Returns: The complex hyperbolic sine of `x`.

```
template<class T> complex<T> sqrt(const complex<T>& x);
```

Returns: The complex square root of `x`, in the range of the right half-plane.

NOTE 2 The semantics of this function are intended to be the same in C++ as they are for `csqrt` in C.

Remarks: The branch cuts are along the negative real axis.

```
template<class T> complex<T> tan(const complex<T>& x);
```

Returns: The complex tangent of `x`.

```
template<class T> complex<T> tanh(const complex<T>& x);
```

Returns: The complex hyperbolic tangent of `x`.

28.4.9 Additional overloads

[`cmplx.over`]

The following function templates shall have additional overloads:

<code>arg</code>	<code>norm</code>
<code>conj</code>	<code>proj</code>
<code>imag</code>	<code>real</code>

where `norm`, `conj`, `imag`, and `real` are `constexpr` overloads.

The additional overloads shall be sufficient to ensure:

- If the argument has a floating-point type `T`, then it is effectively cast to `complex<T>`.
- Otherwise, if the argument has integer type, then it is effectively cast to `complex<double>`.

Function template `pow` has additional overloads sufficient to ensure, for a call with one argument of type `complex<T1>` and the other argument of type `T2` or `complex<T2>`, both arguments are effectively cast to `complex<common_type_t<T1, T2>>`. If `common_type_t<T1, T2>` is not well-formed, then the program is ill-formed.

28.4.10 Suffixes for complex number literals

[`complex.literals`]

This subclause describes literal suffixes for constructing complex number literals. The suffixes `i`, `il`, and `if` create complex numbers of the types `complex<double>`, `complex<long double>`, and `complex<float>` respectively, with their imaginary part denoted by the given literal number and the real part being zero.

```
constexpr complex<long double> operator""il(long double d);
```

```
constexpr complex<long double> operator""il(unsigned long long d);
```

Returns: `complex<long double>{0.0L, static_cast<long double>(d)}`.

```
constexpr complex<double> operator""i(long double d);
constexpr complex<double> operator""i(unsigned long long d);
```

Returns: `complex<double>{0.0, static_cast<double>(d)}`.

```
constexpr complex<float> operator""if(long double d);
constexpr complex<float> operator""if(unsigned long long d);
```

Returns: `complex<float>{0.0f, static_cast<float>(d)}`.

28.5 Random number generation

[rand]

28.5.1 General

[rand.general]

Subclause 28.5 defines a facility for generating (pseudo-)random numbers.

In addition to a few utilities, four categories of entities are described: *uniform random bit generators*, *random number engines*, *random number engine adaptors*, and *random number distributions*. These categorizations are applicable to types that meet the corresponding requirements, to objects instantiated from such types, and to templates producing such types when instantiated.

NOTE These entities are specified in such a way as to permit the binding of any uniform random bit generator object `e` as the argument to any random number distribution object `d`, thus producing a zero-argument function object such as given by `bind(d,e)`.

Each of the entities specified in 28.5 has an associated arithmetic type (6.8.2) identified as `result_type`. With `T` as the `result_type` thus associated with such an entity, that entity is characterized:

- as *boolean* or equivalently as *boolean-valued*, if `T` is `bool`;
- otherwise as *integral* or equivalently as *integer-valued*, if `numeric_limits<T>::is_integer` is `true`;
- otherwise as *floating-point* or equivalently as *real-valued*.

If integer-valued, an entity may optionally be further characterized as *signed* or *unsigned*, according to `numeric_limits<T>::is_signed`.

Unless otherwise specified, all descriptions of calculations in 28.5 use mathematical real numbers.

Throughout 28.5, the operators `bitand`, `bitor`, and `xor` denote the respective conventional bitwise operations. Further:

- the operator `rshift` denotes a bitwise right shift with zero-valued bits appearing in the high bits of the result, and
- the operator `lshiftw` denotes a bitwise left shift with zero-valued bits appearing in the low bits of the result, and whose result is always taken modulo 2^w .

28.5.2 Header <random> synopsis

[rand.synopsis]

```
#include <initializer_list> // see 17.10.2

namespace std {
    // 28.5.3.3, uniform random bit generator requirements
    template<class G>
        concept uniform_random_bit_generator = see below;

}

```

28.5.3 Requirements

[rand.req]

28.5.3.1 General requirements

[rand.req.genl]

Throughout 28.5, the effect of instantiating a template:

- that has a template type parameter named `Sseq` is undefined unless the corresponding template argument is cv-unqualified and meets the requirements of seed sequence (28.5.3.2).
- that has a template type parameter named `URBG` is undefined unless the corresponding template argument is cv-unqualified and meets the requirements of uniform random bit generator (28.5.3.3).

- that has a template type parameter named **Engine** is undefined unless the corresponding template argument is cv-unqualified and meets the requirements of random number engine (28.5.3.4).
- that has a template type parameter named **RealType** is undefined unless the corresponding template argument is cv-unqualified and is one of **float**, **double**, or **long double**.
- that has a template type parameter named **IntType** is undefined unless the corresponding template argument is cv-unqualified and is one of **short**, **int**, **long**, **long long**, **unsigned short**, **unsigned int**, **unsigned long**, or **unsigned long long**.
- that has a template type parameter named **UIntType** is undefined unless the corresponding template argument is cv-unqualified and is one of **unsigned short**, **unsigned int**, **unsigned long**, or **unsigned long long**.

Throughout 28.5, phrases of the form “**x** is an iterator of a specific kind” shall be interpreted as equivalent to the more formal requirement that “**x** is a value of a type meeting the requirements of the specified iterator type”.

Throughout 28.5, any constructor that can be called with a single argument and that meets a requirement specified in this subclause shall be declared **explicit**.

28.5.3.2 Seed sequence requirements [rand.req.seedseq]

A *seed sequence* is an object that consumes a sequence of integer-valued data and produces a requested number of unsigned integer values i , $0 \leq i < 2^{32}$, based on the consumed data.

NOTE Such an object provides a mechanism to avoid replication of streams of random variates. This can be useful, for example, in applications requiring large numbers of random number engines.

A class **S** meets the requirements of a seed sequence if the expressions shown in Table 95 are valid and have the indicated semantics, and if **S** also meets all other requirements of 28.5.3.2. In Table 95 and throughout this subclause:

- **T** is the type named by **S**’s associated **result_type**;
- **q** is a value of type **S** and **r** is a value of type **S** or **const S**;
- **ib** and **ie** are input iterators with an unsigned integer **value_type** of at least 32 bits;
- **rb** and **re** are mutable random access iterators with an unsigned integer **value_type** of at least 32 bits;
- **ob** is an output iterator; and
- **il** is a value of type **initializer_list<T>**.

Table 95 — Seed sequence requirements [tab:rand.req.seedseq]

Expression	Return type	Pre/post-condition	Complexity
S::result_type	T	T is an unsigned integer type (6.8.2) of at least 32 bits.	compile-time
S()		Creates a seed sequence with the same initial state as all other default-constructed seed sequences of type S .	constant
S(ib, ie)		Creates a seed sequence having internal state that depends on some or all of the bits of the supplied sequence [ib, ie).	$\mathcal{O}(\text{ie} - \text{ib})$
S(il)		Same as S(il.begin(), il.end()) .	same as S(il.begin(), il.end())

Table 95 — Seed sequence requirements (continued)

Expression	Return type	Pre/post-condition	Complexity
<code>q.generate(rb, re)</code>	<code>void</code>	Does nothing if <code>rb == re</code> . Otherwise, fills the supplied sequence <code>[rb, re)</code> with 32-bit quantities that depend on the sequence supplied to the constructor and possibly also depend on the history of <code>generate</code> 's previous invocations.	$\mathcal{O}(\text{re} - \text{rb})$
<code>r.size()</code>	<code>size_t</code>	The number of 32-bit units that would be copied by a call to <code>r.param</code> .	constant
<code>r.param(ob)</code>	<code>void</code>	Copies to the given destination a sequence of 32-bit units that can be provided to the constructor of a second object of type <code>S</code> , and that would reproduce in that second object a state indistinguishable from the state of the first object.	$\mathcal{O}(\text{r.size}())$

28.5.3.3 Uniform random bit generator requirements

[rand.req.urng]

A *uniform random bit generator* `g` of type `G` is a function object returning unsigned integer values such that each value in the range of possible results has (ideally) equal probability of being returned.

NOTE The degree to which `g`'s results approximate the ideal is often determined statistically.

```
template<class G>
concept uniform_random_bit_generator =
    invocable<G&&> && unsigned_integral<invoke_result_t<G&&>> &&
    requires {
        { G::min() } -> same_as<invoke_result_t<G&&>>;
        { G::max() } -> same_as<invoke_result_t<G&&>>;
        requires bool_constant<(G::min() < G::max())>::value;
    };

```

Let `g` be an object of type `G`. `G` models `uniform_random_bit_generator` only if

- `G::min() <= g()`,
- `g() <= G::max()`, and
- `g()` has amortized constant complexity.

A class `G` meets the *uniform random bit generator* requirements if `G` models `uniform_random_bit_generator`, `invoke_result_t<G&&>` is an unsigned integer type (6.8.2), and `G` provides a nested *typedef-name* `result_type` that denotes the same type as `invoke_result_t<G&&>`.

28.5.3.4 Random number engine requirements

[rand.req.eng]

A *random number engine* (commonly shortened to *engine*) `e` of type `E` is a uniform random bit generator that additionally meets the requirements (e.g., for seeding and for input/output) specified in this subclause.

At any given time, `e` has a state `ei` for some integer $i \geq 0$. Upon construction, `e` has an initial state `e0`. An engine's state may be established via a constructor, a `seed` function, assignment, or a suitable `operator>>`.

`E`'s specification shall define:

- the size of `E`'s state in multiples of the size of `result_type`, given as an integral constant expression;
- the *transition algorithm* `TA` by which `e`'s state `ei` is advanced to its *successor state* `ei+1`; and
- the *generation algorithm* `GA` by which an engine's state is mapped to a value of type `result_type`.

A class **E** that meets the requirements of a uniform random bit generator (28.5.3.3) also meets the requirements of a *random number engine* if the expressions shown in Table 96 are valid and have the indicated semantics, and if **E** also meets all other requirements of 28.5.3.4. In Table 96 and throughout this subclause:

- **T** is the type named by **E**'s associated `result_type`;
- **e** is a value of **E**, **v** is an lvalue of **E**, **x** and **y** are (possibly const) values of **E**;
- **s** is a value of **T**;
- **q** is an lvalue meeting the requirements of a seed sequence (28.5.3.2);
- **z** is a value of type `unsigned long long`;
- **os** is an lvalue of the type of some class template specialization `basic_ostream<charT, traits>`; and
- **is** is an lvalue of the type of some class template specialization `basic_istream<charT, traits>`;

where `charT` and `traits` are constrained according to Clause 23 and Clause 31.

Table 96 — Random number engine requirements [tab:rand.req.eng]

Expression	Return type	Pre/post-condition	Complexity
E ()		Creates an engine with the same initial state as all other default-constructed engines of type E .	$\mathcal{O}$ (size of state)
E (x)		Creates an engine that compares equal to x .	$\mathcal{O}$ (size of state)
E (s)		Creates an engine with initial state determined by s .	$\mathcal{O}$ (size of state)
E (q) ²²⁵		Creates an engine with an initial state that depends on a sequence produced by one call to q.generate .	same as complexity of q.generate called on a sequence whose length is size of state
e.seed ()	<code>void</code>	<i>Postconditions:</i> e == E () .	same as E ()
e.seed (s)	<code>void</code>	<i>Postconditions:</i> e == E (s) .	same as E (s)
e.seed (q)	<code>void</code>	<i>Postconditions:</i> e == E (q) .	same as E (q)
e ()	T	Advances e 's state e_i to e_{i+1} = TA (e_i) and returns GA (e_i) .	per 28.5.3.3
e.discard (z) ²²⁶	<code>void</code>	Advances e 's state e_i to e_{i+z} by any means equivalent to z consecutive calls e () .	no worse than the complexity of z consecutive calls e ()
x == y	<code>bool</code>	This operator is an equivalence relation. With S_x and S_y as the infinite sequences of values that would be generated by repeated future calls to x () and y () , respectively, returns true if S_x = S_y ; else returns false .	$\mathcal{O}$ (size of state)
x != y	<code>bool</code>	!(x == y) .	$\mathcal{O}$ (size of state)

225) This constructor (as well as the subsequent corresponding `seed()` function) can be particularly useful to applications requiring a large number of independent random sequences.

226) This operation is common in user code, and can often be implemented in an engine-specific manner so as to provide significant performance improvements over an equivalent naive loop that makes **z** consecutive calls **e**() .

Table 96 — Random number engine requirements (continued)

Expression	Return type	Pre/post-condition	Complexity
<code>os << x</code>	reference to the type of <code>os</code>	With <code>os.fmtflags</code> set to <code>ios_base::dec ios_base::left</code> and the fill character set to the space character, writes to <code>os</code> the textual representation of <code>x</code> 's current state. In the output, adjacent numbers are separated by one or more space characters. <i>Postconditions:</i> The <code>os.fmtflags</code> and fill character are unchanged.	$\mathcal{O}(\text{size of state})$
<code>is >> v</code>	reference to the type of <code>is</code>	With <code>is.fmtflags</code> set to <code>ios_base::dec</code> , sets <code>v</code> 's state as determined by reading its textual representation from <code>is</code> . If bad input is encountered, ensures that <code>v</code> 's state is unchanged by the operation and calls <code>is.setstate(ios_base::failbit)</code> (which may throw <code>ios_base::failure</code> (31.5.4.4)). If a textual representation written via <code>os << x</code> was subsequently read via <code>is >> v</code> , then <code>x == v</code> provided that there have been no intervening invocations of <code>x</code> or of <code>v</code> . <i>Preconditions:</i> <code>is</code> provides a textual representation that was previously written using an output stream whose imbued locale was the same as that of <code>is</code> , and whose type's template specialization arguments <code>charT</code> and <code>traits</code> were respectively the same as those of <code>is</code> . <i>Postconditions:</i> The <code>is.fmtflags</code> are unchanged.	$\mathcal{O}(\text{size of state})$

E shall meet the *Cpp17CopyConstructible* (Table 32) and *Cpp17CopyAssignable* (Table 34) requirements. These operations shall each be of complexity no worse than $\mathcal{O}(\text{size of state})$.

28.5.3.5 Random number engine adaptor requirements

[rand.req.adapt]

A *random number engine adaptor* (commonly shortened to *adaptor*) `a` of type `A` is a random number engine that takes values produced by some other random number engine, and applies an algorithm to those values in order to deliver a sequence of values with different randomness properties. An engine `b` of type `B` adapted in this way is termed a *base engine* in this context. The expression `a.base()` shall be valid and shall return a const reference to `a`'s base engine.

The requirements of a random number engine type shall be interpreted as follows with respect to a random number engine adaptor type.

`A::A();`

Effects: The base engine is initialized as if by its default constructor.

```
bool operator==(const A& a1, const A& a2);
```

Returns: `true` if `a1`'s base engine is equal to `a2`'s base engine. Otherwise returns `false`.

```
A::A(result_type s);
```

Effects: The base engine is initialized with `s`.

```
template<class Sseq> A::A(Sseq& q);
```

Effects: The base engine is initialized with `q`.

```
void seed();
```

Effects: With `b` as the base engine, invokes `b.seed()`.

```
void seed(result_type s);
```

Effects: With `b` as the base engine, invokes `b.seed(s)`.

```
template<class Sseq> void seed(Sseq& q);
```

Effects: With `b` as the base engine, invokes `b.seed(q)`.

A shall also meet the following additional requirements:

- The complexity of each function shall not exceed the complexity of the corresponding function applied to the base engine.
- The state of `A` shall include the state of its base engine. The size of `A`'s state shall be no less than the size of the base engine.
- Copying `A`'s state (e.g., during copy construction or copy assignment) shall include copying the state of the base engine of `A`.
- The textual representation of `A` shall include the textual representation of its base engine.

28.5.3.6 Random number distribution requirements

[rand.req.dist]

A *random number distribution* (commonly shortened to *distribution*) `d` of type `D` is a function object returning values that are distributed according to an associated mathematical *probability density function* $p(z)$ or according to an associated *discrete probability function* $P(z_i)$. A distribution's specification identifies its associated probability function $p(z)$ or $P(z_i)$.

An associated probability function is typically expressed using certain externally-supplied quantities known as the *parameters of the distribution*. Such distribution parameters are identified in this context by writing, for example, $p(z | a, b)$ or $P(z_i | a, b)$, to name specific parameters, or by writing, for example, $p(z | \{p\})$ or $P(z_i | \{p\})$, to denote a distribution's parameters `p` taken as a whole.

A class `D` meets the requirements of a *random number distribution* if the expressions shown in Table 97 are valid and have the indicated semantics, and if `D` and its associated types also meet all other requirements of 28.5.3.6. In Table 97 and throughout this subclause,

- `T` is the type named by `D`'s associated `result_type`;
- `P` is the type named by `D`'s associated `param_type`;
- `d` is a value of `D`, and `x` and `y` are (possibly `const`) values of `D`;
- `glb` and `lub` are values of `T` respectively corresponding to the greatest lower bound and the least upper bound on the values potentially returned by `d.operator()`, as determined by the current values of `d`'s parameters;
- `p` is a (possibly `const`) value of `P`;
- `g`, `g1`, and `g2` are lvalues of a type meeting the requirements of a uniform random bit generator (28.5.3.3);
- `os` is an lvalue of the type of some class template specialization `basic_ostream<charT, traits>`; and
- `is` is an lvalue of the type of some class template specialization `basic_istream<charT, traits>`;

where `charT` and `traits` are constrained according to Clause 23 and Clause 31.

Table 97 — Random number distribution requirements [tab:rand.req.dist]

Expression	Return type	Pre/post-condition	Complexity
<code>D::result_type</code>	T	T is an arithmetic type (6.8.2).	compile-time
<code>D::param_type</code>	P		compile-time
<code>D()</code>		Creates a distribution whose behavior is indistinguishable from that of any other newly default-constructed distribution of type D.	constant
<code>D(p)</code>		Creates a distribution whose behavior is indistinguishable from that of a distribution newly constructed directly from the values used to construct p.	same as p's construction
<code>d.reset()</code>	void	Subsequent uses of d do not depend on values produced by any engine prior to invoking <code>reset</code> .	constant
<code>x.param()</code>	P	Returns a value p such that <code>D(p).param() == p</code> .	no worse than the complexity of D(p)
<code>d.param(p)</code>	void	<i>Postconditions:</i> <code>d.param() == p</code> .	no worse than the complexity of D(p)
<code>d(g)</code>	T	With <code>p = d.param()</code> , the sequence of numbers returned by successive invocations with the same object g is randomly distributed according to the associated $p(z \{p\})$ or $P(z_i \{p\})$ function.	amortized constant number of invocations of g
<code>d(g,p)</code>	T	The sequence of numbers returned by successive invocations with the same objects g and p is randomly distributed according to the associated $p(z \{p\})$ or $P(z_i \{p\})$ function.	amortized constant number of invocations of g
<code>x.min()</code>	T	Returns glb.	constant
<code>x.max()</code>	T	Returns lub.	constant
<code>x == y</code>	bool	This operator is an equivalence relation. Returns <code>true</code> if <code>x.param() == y.param()</code> and $S_1 = S_2$, where S_1 and S_2 are the infinite sequences of values that would be generated, respectively, by repeated future calls to <code>x(g1)</code> and <code>y(g2)</code> whenever <code>g1 == g2</code> . Otherwise returns <code>false</code> .	constant
<code>x != y</code>	bool	<code>!(x == y)</code> .	same as <code>x == y</code> .
<code>os << x</code>	reference to the type of os	Writes to os a textual representation for the parameters and the additional internal data of x. <i>Postconditions:</i> The <code>os.fmtflags</code> and fill character are unchanged.	

Table 97 — Random number distribution requirements (continued)

Expression	Return type	Pre/post-condition	Complexity
<code>is >> d</code>	reference to the type of <code>is</code>	Restores from <code>is</code> the parameters and additional internal data of the lvalue <code>d</code> . If bad input is encountered, ensures that <code>d</code> is unchanged by the operation and calls <code>is.setstate(ios_base::failbit)</code> (which may throw <code>ios_base::failure</code> (31.5.4.4)). <i>Preconditions:</i> <code>is</code> provides a textual representation that was previously written using an <code>os</code> whose imbued locale and whose type's template specialization arguments <code>charT</code> and <code>traits</code> were the same as those of <code>is</code> . <i>Postconditions:</i> The <code>is.flags</code> are unchanged.	

`D` shall meet the *Cpp17CopyConstructible* (Table 32) and *Cpp17CopyAssignable* (Table 34) requirements.

The sequence of numbers produced by repeated invocations of `d(g)` shall be independent of any invocation of `os << d` or of any `const` member function of `D` between any of the invocations of `d(g)`.

If a textual representation is written using `os << x` and that representation is restored into the same or a different object `y` of the same type using `is >> y`, repeated invocations of `y(g)` shall produce the same sequence of numbers as would repeated invocations of `x(g)`.

It is unspecified whether `D::param_type` is declared as a (nested) `class` or via a `typedef`. In 28.5, declarations of `D::param_type` are in the form of `typedefs` for convenience of exposition only.

`P` shall meet the *Cpp17CopyConstructible* (Table 32), *Cpp17CopyAssignable* (Table 34), and *Cpp17EqualityComparable* (Table 28) requirements.

For each of the constructors of `D` taking arguments corresponding to parameters of the distribution, `P` shall have a corresponding constructor subject to the same requirements and taking arguments identical in number, type, and default values. Moreover, for each of the member functions of `D` that return values corresponding to parameters of the distribution, `P` shall have a corresponding member function with the identical name, type, and semantics.

`P` shall have a declaration of the form

```
using distribution_type = D;
```

28.5.4 Random number engine class templates

[rand.eng]

28.5.4.1 General

[rand.eng.general]

Each type instantiated from a class template specified in 28.5.4 meets the requirements of a random number engine (28.5.3.4) type.

Except where specified otherwise, the complexity of each function specified in 28.5.4 is constant.

Except where specified otherwise, no function described in 28.5.4 throws an exception.

Every function described in 28.5.4 that has a function parameter `q` of type `Sseq&` for a template type parameter named `Sseq` that is different from type `seed_seq` throws what and when the invocation of `q.generate` throws.

Descriptions are provided in 28.5.4 only for engine operations that are not described in 28.5.3.4 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

Each template specified in 28.5.4 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.

For every random number engine and for every random number engine adaptor X defined in 28.5.4 and in 28.5.5:

- if the constructor

```
template<class Sseq> explicit X(Sseq& q);
```

is called with a type Sseq that does not qualify as a seed sequence, then this constructor shall not participate in overload resolution;

- if the member function

```
template<class Sseq> void seed(Sseq& q);
```

is called with a type Sseq that does not qualify as a seed sequence, then this function shall not participate in overload resolution.

The extent to which an implementation determines that a type cannot be a seed sequence is unspecified, except that as a minimum a type shall not qualify as a seed sequence if it is implicitly convertible to `X::result_type`.

28.5.4.2 Class template `linear_congruential_engine`

[rand.eng.lcong]

A `linear_congruential_engine` random number engine produces unsigned integer random numbers. The state x_i of a `linear_congruential_engine` object `x` is of size 1 and consists of a single integer. The transition algorithm is a modular linear function of the form $TA(x_i) = (a \cdot x_i + c) \bmod m$; the generation algorithm is $GA(x_i) = x_{i+1}$.

```
namespace std {
    template<class UIntType, UIntType a, UIntType c, UIntType m>
    class linear_congruential_engine {
    public:
        // types
        using result_type = UIntType;

        // engine characteristics
        static constexpr result_type multiplier = a;
        static constexpr result_type increment = c;
        static constexpr result_type modulus = m;
        static constexpr result_type min() { return c == 0u ? 1u : 0u; }
        static constexpr result_type max() { return m - 1u; }
        static constexpr result_type default_seed = 1u;

        // constructors and seeding functions
        linear_congruential_engine() : linear_congruential_engine(default_seed) {}
        explicit linear_congruential_engine(result_type s);
        template<class Sseq> explicit linear_congruential_engine(Sseq& q);
        void seed(result_type s = default_seed);
        template<class Sseq> void seed(Sseq& q);

        // equality operators
        friend bool operator==(const linear_congruential_engine& x,
                               const linear_congruential_engine& y);

        // generating functions
        result_type operator()();
        void discard(unsigned long long z);

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
            operator<<(basic_ostream<charT, traits>& os, const linear_congruential_engine& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
            operator>>(basic_istream<charT, traits>& is, linear_congruential_engine& x);
    };
}
```

```
};
}
```

If the template parameter `m` is 0, the modulus m used throughout 28.5.4.2 is `numeric_limits<result_type>::max()` plus 1.

NOTE m need not be representable as a value of type `result_type`.

If the template parameter `m` is not 0, the following relations shall hold: $a < m$ and $c < m$.

The textual representation consists of the value of x_i .

```
explicit linear_congruential_engine(result_type s);
```

Effects: If $c \bmod m$ is 0 and $s \bmod m$ is 0, sets the engine's state to 1, otherwise sets the engine's state to $s \bmod m$.

```
template<class Sseq> explicit linear_congruential_engine(Sseq& q);
```

Effects: With $k = \left\lceil \frac{\log_2 m}{32} \right\rceil$ and a an array (or equivalent) of length $k + 3$, invokes `q.generate(a + 0, a + k + 3)` and then computes $S = \left(\sum_{j=0}^{k-1} a_{j+3} \cdot 2^{32j} \right) \bmod m$. If $c \bmod m$ is 0 and S is 0, sets the engine's state to 1, else sets the engine's state to S .

28.5.4.3 Class template `mersenne_twister_engine` [rand.eng.mers]

A `mersenne_twister_engine` random number engine²²⁷ produces unsigned integer random numbers in the closed interval $[0, 2^w - 1]$. The state x_i of a `mersenne_twister_engine` object `x` is of size n and consists of a sequence X of n values of the type delivered by `x`; all subscripts applied to X are to be taken modulo n .

The transition algorithm employs a twisted generalized feedback shift register defined by shift values n and m , a twist value r , and a conditional xor-mask a . To improve the uniformity of the result, the bits of the raw shift register are additionally *tempered* (i.e., scrambled) according to a bit-scrambling matrix defined by values u, d, s, b, t, c , and ℓ .

The state transition is performed as follows:

- Concatenate the upper $w - r$ bits of X_{i-n} with the lower r bits of X_{i+1-n} to obtain an unsigned integer value Y .
- With $\alpha = a \cdot (Y \text{ bitand } 1)$, set X_i to X_{i+m-n} xor $(Y \text{ rshift } 1) \text{ xor } \alpha$.

The sequence X is initialized with the help of an initialization multiplier f .

The generation algorithm determines the unsigned integer values z_1, z_2, z_3, z_4 as follows, then delivers z_4 as its result:

- Let $z_1 = X_i \text{ xor } ((X_i \text{ rshift } u) \text{ bitand } d)$.
- Let $z_2 = z_1 \text{ xor } ((z_1 \text{ lshift}_w s) \text{ bitand } b)$.
- Let $z_3 = z_2 \text{ xor } ((z_2 \text{ lshift}_w t) \text{ bitand } c)$.
- Let $z_4 = z_3 \text{ xor } (z_3 \text{ rshift } \ell)$.

```
namespace std {
    template<class UIntType, size_t w, size_t n, size_t m, size_t r,
            UIntType a, size_t u, UIntType d, size_t s,
            UIntType b, size_t t,
            UIntType c, size_t l, UIntType f>
    class mersenne_twister_engine {
    public:
        // types
        using result_type = UIntType;

        // engine characteristics
        static constexpr size_t word_size = w;
        static constexpr size_t state_size = n;
        static constexpr size_t shift_size = m;
        static constexpr size_t mask_bits = r;
```

²²⁷ The name of this engine refers, in part, to a property of its period: For properly-selected values of the parameters, the period is closely related to a large Mersenne prime number.

```

static constexpr UIntType xor_mask = a;
static constexpr size_t tempering_u = u;
static constexpr UIntType tempering_d = d;
static constexpr size_t tempering_s = s;
static constexpr UIntType tempering_b = b;
static constexpr size_t tempering_t = t;
static constexpr UIntType tempering_c = c;
static constexpr size_t tempering_l = l;
static constexpr UIntType initialization_multiplier = f;
static constexpr result_type min() { return 0; }
static constexpr result_type max() { return 2w - 1; }
static constexpr result_type default_seed = 5489u;

// constructors and seeding functions
mersenne_twister_engine() : mersenne_twister_engine(default_seed) {}
explicit mersenne_twister_engine(result_type value);
template<class Sseq> explicit mersenne_twister_engine(Sseq& q);
void seed(result_type value = default_seed);
template<class Sseq> void seed(Sseq& q);

// equality operators
friend bool operator==(const mersenne_twister_engine& x, const mersenne_twister_engine& y);

// generating functions
result_type operator()();
void discard(unsigned long long z);

// inserters and extractors
template<class charT, class traits>
friend basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const mersenne_twister_engine& x);
template<class charT, class traits>
friend basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, mersenne_twister_engine& x);
};
}

```

The following relations shall hold: $0 < m, m \leq n$, $2u < w$, $r \leq w$, $u \leq w$, $s \leq w$, $t \leq w$, $l \leq w$, $w \leq \text{numeric\_limits}<\text{UIntType}>::\text{digits}$, $a \leq (1u < w) - 1u$, $b \leq (1u < w) - 1u$, $c \leq (1u < w) - 1u$, $d \leq (1u < w) - 1u$, and $f \leq (1u < w) - 1u$.

The textual representation of x , consists of the values of $X_{i-n}, \dots, X_{i-1}$, in that order.

```
explicit mersenne_twister_engine(result_type value);
```

Effects: Sets X_{-n} to $\text{value} \bmod 2^w$. Then, iteratively for $i = 1 - n, \dots, -1$, sets X_i to

$$[f \cdot (X_{i-1} \text{ xor } (X_{i-1} \text{ rshift } (w - 2))) + i \bmod n] \bmod 2^w.$$

Complexity: $\mathcal{O}(n)$.

```
template<class Sseq> explicit mersenne_twister_engine(Sseq& q);
```

Effects: With $k = \lceil w/32 \rceil$ and a an array (or equivalent) of length $n \cdot k$, invokes $q.\text{generate}(a + 0, a + n \cdot k)$ and then, iteratively for $i = -n, \dots, -1$, sets X_i to $\left(\sum_{j=0}^{k-1} a_{k(i+n)+j} \cdot 2^{32j}\right) \bmod 2^w$. Finally, if the most significant $w - r$ bits of X_{-n} are zero, and if each of the other resulting X_i is 0, changes X_{-n} to 2^{w-1} .

28.5.4.4 Class template subtract_with_carry_engine

[rand.eng.sub]

A `subtract_with_carry_engine` random number engine produces unsigned integer random numbers.

The state x_i of a `subtract_with_carry_engine` object x is of size $\mathcal{O}(r)$, and consists of a sequence X of r integer values $0 \leq X_i < m = 2^w$; all subscripts applied to X are to be taken modulo r . The state x_i additionally consists of an integer c (known as the *carry*) whose value is either 0 or 1.

The state transition is performed as follows:

- Let $Y = X_{i-s} - X_{i-r} - c$.
- Set X_i to $y = Y \bmod m$. Set c to 1 if $Y < 0$, otherwise set c to 0.

NOTE This algorithm corresponds to a modular linear function of the form $TA(x_i) = (a \cdot x_i) \bmod b$, where b is of the form $m^r - m^s + 1$ and $a = b - (b - 1)/m$.

The generation algorithm is given by $GA(x_i) = y$, where y is the value produced as a result of advancing the engine's state as described above.

```
namespace std {
    template<class UIntType, size_t w, size_t s, size_t r>
    class subtract_with_carry_engine {
    public:
        // types
        using result_type = UIntType;

        // engine characteristics
        static constexpr size_t word_size = w;
        static constexpr size_t short_lag = s;
        static constexpr size_t long_lag = r;
        static constexpr result_type min() { return 0; }
        static constexpr result_type max() { return m - 1; }
        static constexpr result_type default_seed = 19780503u;

        // constructors and seeding functions
        subtract_with_carry_engine() : subtract_with_carry_engine(default_seed) {}
        explicit subtract_with_carry_engine(result_type value);
        template<class Sseq> explicit subtract_with_carry_engine(Sseq& q);
        void seed(result_type value = default_seed);
        template<class Sseq> void seed(Sseq& q);

        // equality operators
        friend bool operator==(const subtract_with_carry_engine& x,
                               const subtract_with_carry_engine& y);

        // generating functions
        result_type operator()();
        void discard(unsigned long long z);

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
            operator<<(basic_ostream<charT, traits>& os, const subtract_with_carry_engine& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
            operator>>(basic_istream<charT, traits>& is, subtract_with_carry_engine& x);
    };
}
```

The following relations shall hold: $0u < s$, $s < r$, $0 < w$, and $w \leq \text{numeric\_limits}<\text{UIntType}>::\text{digits}$. The textual representation consists of the values of $X_{i-r}, \dots, X_{i-1}$, in that order, followed by c .

```
explicit subtract_with_carry_engine(result_type value);
```

Effects: Sets the values of $X_{-r}, \dots, X_{-1}$, in that order, as specified below. If X_{-1} is then 0, sets c to 1; otherwise sets c to 0.

To set the values X_k , first construct **e**, a `linear_congruential_engine` object, as if by the following definition:

```
linear_congruential_engine<result_type,
    40014u, 0u, 2147483563u> e(value == 0u ? default_seed : value);
```

Then, to set each X_k , obtain new values $z_0, \dots, z_{n-1}$ from $n = \lceil w/32 \rceil$ successive invocations of **e**. Set X_k to $\left(\sum_{j=0}^{n-1} z_j \cdot 2^{32j} \right) \bmod m$.

Complexity: Exactly $n \cdot r$ invocations of **e**.

```
template<class Sseq> explicit subtract_with_carry_engine(Sseq& q);
```

Effects: With $k = \lceil w/32 \rceil$ and a an array (or equivalent) of length $r \cdot k$, invokes $q.generate(a + 0, a + r \cdot k)$ and then, iteratively for $i = -r, \dots, -1$, sets X_i to $\left(\sum_{j=0}^{k-1} a_{k(i+r)+j} \cdot 2^{32j}\right) \bmod m$. If X_{-1} is then 0, sets c to 1; otherwise sets c to 0.

28.5.5 Random number engine adaptor class templates

[rand.adapt]

28.5.5.1 General

[rand.adapt.general]

Each type instantiated from a class template specified in 28.5.5 meets the requirements of a random number engine adaptor (28.5.3.5) type.

Except where specified otherwise, the complexity of each function specified in 28.5.5 is constant.

Except where specified otherwise, no function described in 28.5.5 throws an exception.

Every function described in 28.5.5 that has a function parameter q of type $Sseq\&$ for a template type parameter named $Sseq$ that is different from type $seed\_seq$ throws what and when the invocation of $q.generate$ throws.

Descriptions are provided in 28.5.5 only for adaptor operations that are not described in subclause 28.5.3.5 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

Each template specified in 28.5.5 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.

28.5.5.2 Class template discard_block_engine

[rand.adapt.disc]

A `discard_block_engine` random number engine adaptor produces random numbers selected from those produced by some base engine e . The state x_i of a `discard_block_engine` engine adaptor object x consists of the state e_i of its base engine e and an additional integer n . The size of the state is the size of e 's state plus 1.

The transition algorithm discards all but $r > 0$ values from each block of $p \geq r$ values delivered by e . The state transition is performed as follows: If $n \geq r$, advance the state of e from e_i to e_{i+p-r} and set n to 0. In any case, then increment n and advance e 's then-current state e_j to e_{j+1} .

The generation algorithm yields the value returned by the last invocation of $e()$ while advancing e 's state as described above.

```
namespace std {
    template<class Engine, size_t p, size_t r>
    class discard_block_engine {
    public:
        // types
        using result_type = typename Engine::result_type;

        // engine characteristics
        static constexpr size_t block_size = p;
        static constexpr size_t used_block = r;
        static constexpr result_type min() { return Engine::min(); }
        static constexpr result_type max() { return Engine::max(); }

        // constructors and seeding functions
        discard_block_engine();
        explicit discard_block_engine(const Engine& e);
        explicit discard_block_engine(Engine&& e);
        explicit discard_block_engine(result_type s);
        template<class Sseq> explicit discard_block_engine(Sseq& q);
        void seed();
        void seed(result_type s);
        template<class Sseq> void seed(Sseq& q);

        // equality operators
        friend bool operator==(const discard_block_engine& x, const discard_block_engine& y);
```

```

// generating functions
result_type operator()();
void discard(unsigned long long z);

// property functions
const Engine& base() const noexcept { return e; }

// inserters and extractors
template<class charT, class traits>
friend basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const discard_block_engine& x);
template<class charT, class traits>
friend basic_istream<charT, traits>&
    operator>>(basic_istream<charT, traits>& is, discard_block_engine& x);

private:
    Engine e;    // exposition only
    size_t n;    // exposition only
};
}

```

The following relations shall hold: $0 < r$ and $r \leq p$.

The textual representation consists of the textual representation of e followed by the value of n .

In addition to its behavior pursuant to subclause 28.5.3.5, each constructor that is not a copy constructor sets n to 0.

28.5.5.3 Class template independent_bits_engine [rand.adapt.ibits]

An `independent_bits_engine` random number engine adaptor combines random numbers that are produced by some base engine e , so as to produce random numbers with a specified number of bits w . The state x_i of an `independent_bits_engine` engine adaptor object x consists of the state e_i of its base engine e ; the size of the state is the size of e 's state.

The transition and generation algorithms are described in terms of the following integral constants:

- Let $R = e.max() - e.min() + 1$ and $m = \lfloor \log_2 R \rfloor$.
- With n as determined below, let $w_0 = \lfloor w/n \rfloor$, $n_0 = n - w \bmod n$, $y_0 = 2^{w_0} \lfloor R/2^{w_0} \rfloor$, and $y_1 = 2^{w_0+1} \lfloor R/2^{w_0+1} \rfloor$.
- Let $n = \lceil w/m \rceil$ if and only if the relation $R - y_0 \leq \lfloor y_0/n \rfloor$ holds as a result. Otherwise let $n = 1 + \lceil w/m \rceil$.

NOTE The relation $w = n_0 w_0 + (n - n_0)(w_0 + 1)$ always holds.

The transition algorithm is carried out by invoking $e()$ as often as needed to obtain n_0 values less than $y_0 + e.min()$ and $n - n_0$ values less than $y_1 + e.min()$.

The generation algorithm uses the values produced while advancing the state as described above to yield a quantity S obtained as if by the following algorithm:

```

S = 0;
for (k = 0; k < n_0; k += 1) {
    do u = e() - e.min(); while (u >= y_0);
    S = 2^{w_0} * S + u mod 2^{w_0};
}
for (k = n_0; k < n; k += 1) {
    do u = e() - e.min(); while (u >= y_1);
    S = 2^{w_0+1} * S + u mod 2^{w_0+1};
}

template<class Engine, size_t w, class UIntType>
class independent_bits_engine {
public:
    // types
    using result_type = UIntType;

    // engine characteristics
    static constexpr result_type min() { return 0; }

```

```

static constexpr result_type max() { return 2w - 1; }

// constructors and seeding functions
independent_bits_engine();
explicit independent_bits_engine(const Engine& e);
explicit independent_bits_engine(Engine&& e);
explicit independent_bits_engine(result_type s);
template<class Sseq> explicit independent_bits_engine(Sseq& q);
void seed();
void seed(result_type s);
template<class Sseq> void seed(Sseq& q);

// equality operators
friend bool operator==(const independent_bits_engine& x, const independent_bits_engine& y);

// generating functions
result_type operator()();
void discard(unsigned long long z);

// property functions
const Engine& base() const noexcept { return e; }

// inserters and extractors
template<class charT, class traits>
    friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const independent_bits_engine& x);
template<class charT, class traits>
    friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, independent_bits_engine& x);

private:
    Engine e;    // exposition only
};

```

The following relations shall hold: $0 < w$ and $w \leq \text{numeric\_limits}<\text{result\_type}>::\text{digits}$.

The textual representation consists of the textual representation of e .

28.5.5.4 Class template `shuffle_order_engine` [rand.adapt.shuf]

A `shuffle_order_engine` random number engine adaptor produces the same random numbers that are produced by some base engine e , but delivers them in a different sequence. The state x_i of a `shuffle_order_engine` engine adaptor object x consists of the state e_i of its base engine e , an additional value Y of the type delivered by e , and an additional sequence V of k values also of the type delivered by e . The size of the state is the size of e 's state plus $k + 1$.

The transition algorithm permutes the values produced by e . The state transition is performed as follows:

- Calculate an integer $j = \left\lfloor \frac{k \cdot (Y - e_{\min})}{e_{\max} - e_{\min} + 1} \right\rfloor$.
- Set Y to V_j and then set V_j to $e()$.

The generation algorithm yields the last value of Y produced while advancing e 's state as described above.

```

namespace std {
    template<class Engine, size_t k>
    class shuffle_order_engine {
    public:
        // types
        using result_type = typename Engine::result_type;

        // engine characteristics
        static constexpr size_t table_size = k;
        static constexpr result_type min() { return Engine::min(); }
        static constexpr result_type max() { return Engine::max(); }
    };

```

```

// constructors and seeding functions
shuffle_order_engine();
explicit shuffle_order_engine(const Engine& e);
explicit shuffle_order_engine(Engine&& e);
explicit shuffle_order_engine(result_type s);
template<class Sseq> explicit shuffle_order_engine(Sseq& q);
void seed();
void seed(result_type s);
template<class Sseq> void seed(Sseq& q);

// equality operators
friend bool operator==(const shuffle_order_engine& x, const shuffle_order_engine& y);

// generating functions
result_type operator()();
void discard(unsigned long long z);

// property functions
const Engine& base() const noexcept { return e; }

// inserters and extractors
template<class charT, class traits>
    friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const shuffle_order_engine& x);
template<class charT, class traits>
    friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, shuffle_order_engine& x);

private:
    Engine e;           // exposition only
    result_type V[k];    // exposition only
    result_type Y;       // exposition only
};
}

```

The following relation shall hold: $0 < k$.

The textual representation consists of the textual representation of **e**, followed by the **k** values of **V**, followed by the value of **Y**.

In addition to its behavior pursuant to subclause 28.5.3.5, each constructor that is not a copy constructor initializes **V**[0], ..., **V**[**k**-1] and **Y**, in that order, with values returned by successive invocations of **e**().

28.5.6 Engines and engine adaptors with predefined parameters [rand.predef]

```
using minstd_rand0 =
    linear_congruential_engine<uint_fast32_t, 16'807, 0, 2'147'483'647>;
```

Required behavior: The 10000th consecutive invocation of a default-constructed object of type **minstd_rand0** produces the value 1043618065.

```
using minstd_rand =
    linear_congruential_engine<uint_fast32_t, 48'271, 0, 2'147'483'647>;
```

Required behavior: The 10000th consecutive invocation of a default-constructed object of type **minstd_rand** produces the value 399268537.

```
using mt19937 =
    mersenne_twister_engine<uint_fast32_t, 32, 624, 397, 31,
        0x9908'b0df, 11, 0xffff'ffff, 7, 0x9d2c'5680, 15, 0xefc6'0000, 18, 1'812'433'253>;
```

Required behavior: The 10000th consecutive invocation of a default-constructed object of type **mt19937** produces the value 4123659995.

```
using mt19937_64 =
    mersenne_twister_engine<uint_fast64_t, 64, 312, 156, 31,
        0xb502'6f5a'a966'19e9, 29, 0x5555'5555'5555'5555, 17,
        0x71d6'7fff'eda6'0000, 37, 0xffff'7'eee0'0000'0000, 43, 6'364'136'223'846'793'005>;
```

Required behavior: The 10000th consecutive invocation of a default-constructed object of type `mt19937_64` produces the value 9981545732273789042.

```
using ranlux24_base =
    subtract_with_carry_engine<uint_fast32_t, 24, 10, 24>;
```

Required behavior: The 10000th consecutive invocation of a default-constructed object of type `ranlux24_base` produces the value 7937952.

```
using ranlux48_base =
    subtract_with_carry_engine<uint_fast64_t, 48, 5, 12>;
```

Required behavior: The 10000th consecutive invocation of a default-constructed object of type `ranlux48_base` produces the value 61839128582725.

```
using ranlux24 = discard_block_engine<ranlux24_base, 223, 23>;
```

Required behavior: The 10000th consecutive invocation of a default-constructed object of type `ranlux24` produces the value 9901578.

```
using ranlux48 = discard_block_engine<ranlux48_base, 389, 11>;
```

Required behavior: The 10000th consecutive invocation of a default-constructed object of type `ranlux48` produces the value 249142670248501.

```
using knuth_b = shuffle_order_engine<minstd_rand0, 256>;
```

Required behavior: The 10000th consecutive invocation of a default-constructed object of type `knuth_b` produces the value 1112339016.

```
using default_random_engine = implementation-defined;
```

Remarks: The choice of engine type named by this `typedef` is implementation-defined.

NOTE The implementation can select this type on the basis of performance, size, quality, or any combination of such factors, so as to provide at least acceptable engine behavior for relatively casual, inexperienced, and/or lightweight use. Because different implementations can select different underlying engine types, code that uses this `typedef` need not generate identical sequences across implementations.

28.5.7 Class `random_device` [rand.device]

A `random_device` uniform random bit generator produces nondeterministic random numbers.

If implementation limitations prevent generating nondeterministic random numbers, the implementation may employ a random number engine.

```
namespace std {
    class random_device {
    public:
        // types
        using result_type = unsigned int;

        // generator characteristics
        static constexpr result_type min() { return numeric_limits<result_type>::min(); }
        static constexpr result_type max() { return numeric_limits<result_type>::max(); }

        // constructors
        random_device() : random_device(implementation-defined) {}
        explicit random_device(const string& token);

        // generating functions
        result_type operator()();

        // property functions
        double entropy() const noexcept;
```

```

    // no copy functions
    random_device(const random_device&) = delete;
    void operator=(const random_device&) = delete;
};
}

```

```
explicit random_device(const string& token);
```

Throws: A value of an implementation-defined type derived from `exception` if the `random_device` cannot be initialized.

Remarks: The semantics of the `token` parameter and the token value used by the default constructor are implementation-defined.²²⁸

```
double entropy() const noexcept;
```

Returns: If the implementation employs a random number engine, returns 0.0. Otherwise, returns an entropy estimate²²⁹ for the random numbers returned by `operator()`, in the range `min()` to `log2(max() + 1)`.

```
result_type operator()();
```

Returns: A nondeterministic random value, uniformly distributed between `min()` and `max()` (inclusive). It is implementation-defined how these values are generated.

Throws: A value of an implementation-defined type derived from `exception` if a random number cannot be obtained.

28.5.8 Utilities

[rand.util]

28.5.8.1 Class `seed_seq`

[rand.util.seedseq]

```

namespace std {
    class seed_seq {
    public:
        // types
        using result_type = uint_least32_t;

        // constructors
        seed_seq() noexcept;
        template<class T>
            seed_seq(initializer_list<T> il);
        template<class InputIterator>
            seed_seq(InputIterator begin, InputIterator end);

        // generating functions
        template<class RandomAccessIterator>
            void generate(RandomAccessIterator begin, RandomAccessIterator end);

        // property functions
        size_t size() const noexcept;
        template<class OutputIterator>
            void param(OutputIterator dest) const;

        // no copy functions
        seed_seq(const seed_seq&) = delete;
        void operator=(const seed_seq&) = delete;

    private:
        vector<result_type> v;    // exposition only
    };
}

```

228) The parameter is intended to allow an implementation to differentiate between different sources of randomness.

229) If a device has n states whose respective probabilities are $P_0, \dots, P_{n-1}$, the device entropy S is defined as

$$S = - \sum_{i=0}^{n-1} P_i \cdot \log P_i.$$

`seed_seq()` noexcept;

Postconditions: `v.empty()` is true.

template<class T>

`seed_seq(initializer_list<T> il);`

Constraints: T is an integer type.

Effects: Same as `seed_seq(il.begin(), il.end())`.

template<class InputIterator>

`seed_seq(InputIterator begin, InputIterator end);`

Mandates: `iterator_traits<InputIterator>::value_type` is an integer type.

Preconditions: `InputIterator` meets the *Cpp17InputIterator* requirements (25.3.5.3).

Effects: Initializes `v` by the following algorithm:

```
for (InputIterator s = begin; s != end; ++s)
    v.push_back((*s) mod 232);
```

template<class RandomAccessIterator>

`void generate(RandomAccessIterator begin, RandomAccessIterator end);`

Mandates: `iterator_traits<RandomAccessIterator>::value_type` is an unsigned integer type capable of accommodating 32-bit quantities.

Preconditions: `RandomAccessIterator` meets the *Cpp17RandomAccessIterator* requirements (25.3.5.7) and the requirements of a mutable iterator.

Effects: Does nothing if `begin == end`. Otherwise, with `s = v.size()` and `n = end - begin`, fills the supplied range `[begin, end)` according to the following algorithm in which each operation is to be carried out modulo 2^{32} , each indexing operator applied to `begin` is to be taken modulo `n`, and $T(x)$ is defined as $x \text{ xor } (x \text{ rshift } 27)$:

- By way of initialization, set each element of the range to the value `0x8b8b8b8b`. Additionally, for use in subsequent steps, let $p = (n - t)/2$ and let $q = p + t$, where

$$t = (n \geq 623) ? 11 : (n \geq 68) ? 7 : (n \geq 39) ? 5 : (n \geq 7) ? 3 : (n - 1)/2;$$

- With m as the larger of $s + 1$ and n , transform the elements of the range: iteratively for $k = 0, \dots, m - 1$, calculate values

$$\begin{aligned} r_1 &= 1664525 \cdot T(\text{begin}[k] \text{ xor } \text{begin}[k + p] \text{ xor } \text{begin}[k - 1]) \\ r_2 &= r_1 + \begin{cases} s & , k = 0 \\ k \bmod n + v[k - 1] & , 0 < k \leq s \\ k \bmod n & , s < k \end{cases} \end{aligned}$$

and, in order, increment `begin[k + p]` by r_1 , increment `begin[k + q]` by r_2 , and set `begin[k]` to r_2 .

- Transform the elements of the range again, beginning where the previous step ended: iteratively for $k = m, \dots, m + n - 1$, calculate values

$$\begin{aligned} r_3 &= 1566083941 \cdot T(\text{begin}[k] + \text{begin}[k + p] + \text{begin}[k - 1]) \\ r_4 &= r_3 - (k \bmod n) \end{aligned}$$

and, in order, update `begin[k + p]` by xoring it with r_3 , update `begin[k + q]` by xoring it with r_4 , and set `begin[k]` to r_4 .

Throws: What and when `RandomAccessIterator` operations of `begin` and `end` throw.

`size_t size()` const noexcept;

Returns: The number of 32-bit units that would be returned by a call to `param()`.

Complexity: Constant time.

```
template<class OutputIterator>
```

```
void param(OutputIterator dest) const;
```

Mandates: Values of type `result_type` are writable (25.3.1) to `dest`.

Preconditions: `OutputIterator` meets the *Cpp17OutputIterator* requirements (25.3.5.4).

Effects: Copies the sequence of prepared 32-bit units to the given destination, as if by executing the following statement:

```
copy(v.begin(), v.end(), dest);
```

Throws: What and when `OutputIterator` operations of `dest` throw.

28.5.8.2 Function template `generate_canonical`

[rand.util.canonical]

```
template<class RealType, size_t bits, class URBG>
```

```
RealType generate_canonical(URBG& g);
```

Effects: Invokes `g()` k times to obtain values $g_0, \dots, g_{k-1}$, respectively. Calculates a quantity S given by Formula 28.1 using arithmetic of type `RealType`:

$$S = \sum_{i=0}^{k-1} (g_i - g.\text{min}()) \cdot R^i \quad (28.1)$$

Returns: S/R^k .

NOTE 1 $0 \leq S/R^k < 1$.

Throws: What and when `g` throws.

Complexity: Exactly $k = \max(1, \lceil b/\log_2 R \rceil)$ invocations of `g`, where b^{230} is the lesser of `numeric_limits<RealType>::digits` and `bits`, and R is the value of `g.max() - g.min() + 1`.

NOTE 2 If the values g_i produced by `g` are uniformly distributed, the instantiation's results are distributed as uniformly as possible. Obtaining a value in this way can be a useful step in the process of transforming a value generated by a uniform random bit generator into a value that can be delivered by a random number distribution.

28.5.9 Random number distribution class templates

[rand.dist]

28.5.9.1 General

[rand.dist.general]

Each type instantiated from a class template specified in 28.5.9 meets the requirements of a random number distribution (28.5.3.6) type.

Descriptions are provided in 28.5.9 only for distribution operations that are not described in 28.5.3.6 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

The algorithms for producing each of the specified distributions are implementation-defined.

The value of each probability density function $p(z)$ and of each discrete probability function $P(z_i)$ specified in this subclause is 0 everywhere outside its stated domain.

28.5.9.2 Uniform distributions

[rand.dist.uni]

28.5.9.2.1 Class template `uniform_int_distribution`

[rand.dist.uni.int]

A `uniform_int_distribution` random number distribution produces random integers i , $a \leq i \leq b$, distributed according to the constant discrete probability function in Formula 28.2.

$$P(i | a, b) = 1/(b - a + 1) \quad (28.2)$$

```
namespace std {
    template<class IntType = int>
    class uniform_int_distribution {
    public:
        // types
        using result_type = IntType;
```

230) b is introduced to avoid any attempt to produce more bits of randomness than can be held in `RealType`.

```

using param_type = unspecified;

// constructors and reset functions
uniform_int_distribution() : uniform_int_distribution(0) {}
explicit uniform_int_distribution(IntType a, IntType b = numeric_limits<IntType>::max());
explicit uniform_int_distribution(const param_type& parm);
void reset();

// equality operators
friend bool operator==(const uniform_int_distribution& x, const uniform_int_distribution& y);

// generating functions
template<class URBG>
    result_type operator()(URBG& g);
template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

// property functions
result_type a() const;
result_type b() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

// inserters and extractors
template<class charT, class traits>
    friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const uniform_int_distribution& x);
template<class charT, class traits>
    friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, uniform_int_distribution& x);
};
}

```

```
explicit uniform_int_distribution(IntType a, IntType b = numeric_limits<IntType>::max());
```

Preconditions: $a \leq b$.

Remarks: a and b correspond to the respective parameters of the distribution.

```
result_type a() const;
```

Returns: The value of the a parameter with which the object was constructed.

```
result_type b() const;
```

Returns: The value of the b parameter with which the object was constructed.

28.5.9.2.2 Class template `uniform_real_distribution` [rand.dist.uni.real]

A `uniform_real_distribution` random number distribution produces random numbers x , $a \leq x < b$, distributed according to the constant probability density function in Formula 28.3.

$$p(x | a, b) = 1/(b - a) \quad (28.3)$$

NOTE This implies that $p(x | a, b)$ is undefined when $a == b$.

```

namespace std {
    template<class RealType = double>
        class uniform_real_distribution {
        public:
            // types
            using result_type = RealType;
            using param_type = unspecified;

```

```

// constructors and reset functions
uniform_real_distribution() : uniform_real_distribution(0.0) {}
explicit uniform_real_distribution(RealType a, RealType b = 1.0);
explicit uniform_real_distribution(const param_type& parm);
void reset();

// equality operators
friend bool operator==(const uniform_real_distribution& x,
                       const uniform_real_distribution& y);

// generating functions
template<class URBG>
    result_type operator()(URBG& g);
template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

// property functions
result_type a() const;
result_type b() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

// inserters and extractors
template<class charT, class traits>
    friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const uniform_real_distribution& x);
template<class charT, class traits>
    friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, uniform_real_distribution& x);
};
}

explicit uniform_real_distribution(RealType a, RealType b = 1.0);

Preconditions:  $a \leq b$  and  $b - a \leq \text{numeric\_limits}<\text{RealType}>::\text{max}()$ .

Remarks:  $a$  and  $b$  correspond to the respective parameters of the distribution.

result_type a() const;

Returns: The value of the  $a$  parameter with which the object was constructed.

result_type b() const;

Returns: The value of the  $b$  parameter with which the object was constructed.

```

28.5.9.3 Bernoulli distributions

[rand.dist.bern]

28.5.9.3.1 Class bernoulli_distribution

[rand.dist.bern.bernoulli]

A `bernoulli` distribution random number distribution produces `bool` values b distributed according to the discrete probability function in Formula 28.4.

$$P(b|p) = \begin{cases} p & \text{if } b = \text{true} \\ 1 - p & \text{if } b = \text{false} \end{cases} \quad (28.4)$$

```

namespace std {
    class bernoulli_distribution {
    public:
        // types
        using result_type = bool;
        using param_type = unspecified;

        // constructors and reset functions
        bernoulli_distribution() : bernoulli_distribution(0.5) {}
        explicit bernoulli_distribution(double p);
    };
}

```

```

explicit bernoulli_distribution(const param_type& parm);
void reset();

// equality operators
friend bool operator==(const bernoulli_distribution& x, const bernoulli_distribution& y);

// generating functions
template<class URBG>
    result_type operator()(URBG& g);
template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

// property functions
double p() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

// inserters and extractors
template<class charT, class traits>
    friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const bernoulli_distribution& x);
template<class charT, class traits>
    friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, bernoulli_distribution& x);
};
}

explicit bernoulli_distribution(double p);

```

Preconditions: $0 \leq p \leq 1$.

Remarks: p corresponds to the parameter of the distribution.

`double p() const;`

Returns: The value of the p parameter with which the object was constructed.

28.5.9.3.2 Class template binomial_distribution [rand.dist.bern.bin]

A `binomial_distribution` random number distribution produces integer values $i \geq 0$ distributed according to the discrete probability function in Formula 28.5.

$$P(i | t, p) = \binom{t}{i} \cdot p^i \cdot (1 - p)^{t-i} \quad (28.5)$$

```

namespace std {
    template<class IntType = int>
    class binomial_distribution {
    public:
        // types
        using result_type = IntType;
        using param_type = unspecified;

        // constructors and reset functions
        binomial_distribution() : binomial_distribution(1) {}
        explicit binomial_distribution(IntType t, double p = 0.5);
        explicit binomial_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const binomial_distribution& x, const binomial_distribution& y);
    };
}

```

```

// generating functions
template<class URBG>
    result_type operator()(URBG& g);
template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

// property functions
IntType t() const;
double p() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

// inserters and extractors
template<class charT, class traits>
    friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const binomial_distribution& x);
template<class charT, class traits>
    friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, binomial_distribution& x);
};
}

explicit binomial_distribution(IntType t, double p = 0.5);

```

Preconditions: $0 \leq p \leq 1$ and $0 \leq t$.

Remarks: *t* and *p* correspond to the respective parameters of the distribution.

IntType t() const;

Returns: The value of the *t* parameter with which the object was constructed.

double p() const;

Returns: The value of the *p* parameter with which the object was constructed.

28.5.9.3.3 Class template `geometric_distribution`

[rand.dist.bern.geo]

A `geometric_distribution` random number distribution produces integer values $i \geq 0$ distributed according to the discrete probability function in Formula 28.6.

$$P(i | p) = p \cdot (1 - p)^i \quad (28.6)$$

```

namespace std {
    template<class IntType = int>
    class geometric_distribution {
    public:
        // types
        using result_type = IntType;
        using param_type = unspecified;

        // constructors and reset functions
        geometric_distribution() : geometric_distribution(0.5) {}
        explicit geometric_distribution(double p);
        explicit geometric_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const geometric_distribution& x, const geometric_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);
    };
}

```

```

// property functions
double p() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

// inserters and extractors
template<class charT, class traits>
    friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const geometric_distribution& x);
template<class charT, class traits>
    friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, geometric_distribution& x);
};
}

explicit geometric_distribution(double p);

```

Preconditions: $0 < p < 1$.

Remarks: p corresponds to the parameter of the distribution.

```
double p() const;
```

Returns: The value of the p parameter with which the object was constructed.

28.5.9.3.4 Class template `negative_binomial_distribution` [rand.dist.bern.negbin]

A `negative_binomial_distribution` random number distribution produces random integers $i \geq 0$ distributed according to the discrete probability function in Formula 28.7.

$$P(i | k, p) = \binom{k+i-1}{i} \cdot p^k \cdot (1-p)^i \quad (28.7)$$

NOTE This implies that $P(i | k, p)$ is undefined when $p = 1$.

```

namespace std {
    template<class IntType = int>
    class negative_binomial_distribution {
    public:
        // types
        using result_type = IntType;
        using param_type = unspecified;

        // constructor and reset functions
        negative_binomial_distribution() : negative_binomial_distribution(1) {}
        explicit negative_binomial_distribution(IntType k, double p = 0.5);
        explicit negative_binomial_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const negative_binomial_distribution& x,
                               const negative_binomial_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        IntType k() const;
        double p() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;
    };
}

```

```

// inserters and extractors
template<class charT, class traits>
    friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const negative_binomial_distribution& x);
template<class charT, class traits>
    friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, negative_binomial_distribution& x);
};
}

explicit negative_binomial_distribution(IntType k, double p = 0.5);

```

Preconditions: $0 < p \leq 1$ and $0 < k$.

Remarks: k and p correspond to the respective parameters of the distribution.

IntType k() const;

Returns: The value of the k parameter with which the object was constructed.

double p() const;

Returns: The value of the p parameter with which the object was constructed.

28.5.9.4 Poisson distributions

[rand.dist.pois]

28.5.9.4.1 Class template poisson_distribution

[rand.dist.pois.poisson]

A `poisson_distribution` random number distribution produces integer values $i \geq 0$ distributed according to the discrete probability function in Formula 28.8.

$$P(i|\mu) = \frac{e^{-\mu} \mu^i}{i!} \quad (28.8)$$

The distribution parameter μ is also known as this distribution's *mean*.

```

template<class IntType = int>
class poisson_distribution
{
public:
    // types
    using result_type = IntType;
    using param_type = unspecified;

    // constructors and reset functions
    poisson_distribution() : poisson_distribution(1.0) {}
    explicit poisson_distribution(double mean);
    explicit poisson_distribution(const param_type& parm);
    void reset();

    // equality operators
    friend bool operator==(const poisson_distribution& x, const poisson_distribution& y);

    // generating functions
    template<class URBG>
        result_type operator()(URBG& g);
    template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

    // property functions
    double mean() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;

    // inserters and extractors
    template<class charT, class traits>
        friend basic_ostream<charT, traits>&
            operator<<(basic_ostream<charT, traits>& os, const poisson_distribution& x);

```

```
template<class charT, class traits>
    friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, poisson_distribution& x);
};
```

```
explicit poisson_distribution(double mean);
```

Preconditions: $0 < \text{mean}$.

Remarks: `mean` corresponds to the parameter of the distribution.

```
double mean() const;
```

Returns: The value of the `mean` parameter with which the object was constructed.

28.5.9.4.2 Class template `exponential_distribution` [rand.dist.pois.exp]

An `exponential_distribution` random number distribution produces random numbers $x > 0$ distributed according to the probability density function in Formula 28.9.

$$p(x | \lambda) = \lambda e^{-\lambda x} \quad (28.9)$$

```
namespace std {
    template<class RealType = double>
    class exponential_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructors and reset functions
        exponential_distribution() : exponential_distribution(1.0) {}
        explicit exponential_distribution(RealType lambda);
        explicit exponential_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const exponential_distribution& x, const exponential_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType lambda() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
            friend basic_ostream<charT, traits>&
                operator<<(basic_ostream<charT, traits>& os, const exponential_distribution& x);
        template<class charT, class traits>
            friend basic_istream<charT, traits>&
                operator>>(basic_istream<charT, traits>& is, exponential_distribution& x);
    };
}
```

```
explicit exponential_distribution(RealType lambda);
```

Preconditions: $0 < \text{lambda}$.

Remarks: `lambda` corresponds to the parameter of the distribution.

RealType lambda() const;

Returns: The value of the lambda parameter with which the object was constructed.

28.5.9.4.3 Class template gamma_distribution [rand.dist.pois.gamma]

A gamma_distribution random number distribution produces random numbers $x > 0$ distributed according to the probability density function in Formula 28.10.

$$p(x | \alpha, \beta) = \frac{e^{-x/\beta}}{\beta^\alpha \cdot \Gamma(\alpha)} \cdot x^{\alpha-1} \quad (28.10)$$

```
namespace std {
    template<class RealType = double>
    class gamma_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructors and reset functions
        gamma_distribution() : gamma_distribution(1.0) {}
        explicit gamma_distribution(RealType alpha, RealType beta = 1.0);
        explicit gamma_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const gamma_distribution& x, const gamma_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType alpha() const;
        RealType beta() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
            friend basic_ostream<charT, traits>&
                operator<<(basic_ostream<charT, traits>& os, const gamma_distribution& x);
        template<class charT, class traits>
            friend basic_istream<charT, traits>&
                operator>>(basic_istream<charT, traits>& is, gamma_distribution& x);
    };
}
```

explicit gamma_distribution(RealType alpha, RealType beta = 1.0);

Preconditions: $0 < \alpha$ and $0 < \beta$.

Remarks: alpha and beta correspond to the parameters of the distribution.

RealType alpha() const;

Returns: The value of the alpha parameter with which the object was constructed.

RealType beta() const;

Returns: The value of the beta parameter with which the object was constructed.

28.5.9.4.4 Class template `weibull_distribution`

[rand.dist.pois.weibull]

A `weibull_distribution` random number distribution produces random numbers $x \geq 0$ distributed according to the probability density function in Formula 28.11.

$$p(x | a, b) = \frac{a}{b} \cdot \left(\frac{x}{b}\right)^{a-1} \cdot \exp\left(-\left(\frac{x}{b}\right)^a\right) \quad (28.11)$$

```
namespace std {
    template<class RealType = double>
    class weibull_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        weibull_distribution() : weibull_distribution(1.0) {}
        explicit weibull_distribution(RealType a, RealType b = 1.0);
        explicit weibull_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const weibull_distribution& x, const weibull_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType a() const;
        RealType b() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
            friend basic_ostream<charT, traits>&
                operator<<(basic_ostream<charT, traits>& os, const weibull_distribution& x);
        template<class charT, class traits>
            friend basic_istream<charT, traits>&
                operator>>(basic_istream<charT, traits>& is, weibull_distribution& x);
    };
}
```

explicit weibull_distribution(RealType a, RealType b = 1.0);

Preconditions: $0 < a$ and $0 < b$.

Remarks: a and b correspond to the respective parameters of the distribution.

RealType a() const;

Returns: The value of the a parameter with which the object was constructed.

RealType b() const;

Returns: The value of the b parameter with which the object was constructed.

28.5.9.4.5 Class template `extreme_value_distribution`

[rand.dist.pois.extreme]

An `extreme_value_distribution` random number distribution produces random numbers x distributed according to the probability density function in Formula 28.12.²³¹

$$p(x|a, b) = \frac{1}{b} \cdot \exp\left(\frac{a-x}{b} - \exp\left(\frac{a-x}{b}\right)\right) \quad (28.12)$$

```

namespace std {
    template<class RealType = double>
    class extreme_value_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        extreme_value_distribution() : extreme_value_distribution(0.0) {}
        explicit extreme_value_distribution(RealType a, RealType b = 1.0);
        explicit extreme_value_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const extreme_value_distribution& x,
                               const extreme_value_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType a() const;
        RealType b() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
            friend basic_ostream<charT, traits>&
                operator<<(basic_ostream<charT, traits>& os, const extreme_value_distribution& x);
        template<class charT, class traits>
            friend basic_istream<charT, traits>&
                operator>>(basic_istream<charT, traits>& is, extreme_value_distribution& x);
    };
}

explicit extreme_value_distribution(RealType a, RealType b = 1.0);

```

Preconditions: $0 < b$.

Remarks: a and b correspond to the respective parameters of the distribution.

`RealType a() const;`

Returns: The value of the a parameter with which the object was constructed.

`RealType b() const;`

Returns: The value of the b parameter with which the object was constructed.

²³¹) The distribution corresponding to this probability density function is also known (with a possible change of variable) as the Gumbel Type I, the log-Weibull, or the Fisher-Tippett Type I distribution.

28.5.9.5 Normal distributions

[rand.dist.norm]

28.5.9.5.1 Class template normal_distribution

[rand.dist.norm.normal]

A `normal_distribution` random number distribution produces random numbers x distributed according to the probability density function in Formula 28.13.

$$p(x|\mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \cdot \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right) \quad (28.13)$$

The distribution parameters μ and σ are also known as this distribution's *mean* and *standard deviation*.

```
namespace std {
    template<class RealType = double>
    class normal_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructors and reset functions
        normal_distribution() : normal_distribution(0.0) {}
        explicit normal_distribution(RealType mean, RealType stddev = 1.0);
        explicit normal_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const normal_distribution& x, const normal_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType mean() const;
        RealType stddev() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
            friend basic_ostream<charT, traits>&
                operator<<(basic_ostream<charT, traits>& os, const normal_distribution& x);
        template<class charT, class traits>
            friend basic_istream<charT, traits>&
                operator>>(basic_istream<charT, traits>& is, normal_distribution& x);
    };
}
```

```
explicit normal_distribution(RealType mean, RealType stddev = 1.0);
```

Preconditions: $0 < \text{stddev}$.

Remarks: `mean` and `stddev` correspond to the respective parameters of the distribution.

```
RealType mean() const;
```

Returns: The value of the `mean` parameter with which the object was constructed.

```
RealType stddev() const;
```

Returns: The value of the `stddev` parameter with which the object was constructed.

28.5.9.5.2 Class template lognormal_distribution**[rand.dist.norm.lognormal]**

A `lognormal_distribution` random number distribution produces random numbers $x > 0$ distributed according to the probability density function in Formula 28.14.

$$p(x | m, s) = \frac{1}{sx\sqrt{2\pi}} \cdot \exp\left(-\frac{(\ln x - m)^2}{2s^2}\right) \quad (28.14)$$

```

namespace std {
    template<class RealType = double>
    class lognormal_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        lognormal_distribution() : lognormal_distribution(0.0) {}
        explicit lognormal_distribution(RealType m, RealType s = 1.0);
        explicit lognormal_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const lognormal_distribution& x, const lognormal_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType m() const;
        RealType s() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
            friend basic_ostream<charT, traits>&
                operator<<(basic_ostream<charT, traits>& os, const lognormal_distribution& x);
        template<class charT, class traits>
            friend basic_istream<charT, traits>&
                operator>>(basic_istream<charT, traits>& is, lognormal_distribution& x);
    };
}

explicit lognormal_distribution(RealType m, RealType s = 1.0);

```

Preconditions: $0 < s$.

Remarks: `m` and `s` correspond to the respective parameters of the distribution.

`RealType m() const;`

Returns: The value of the `m` parameter with which the object was constructed.

`RealType s() const;`

Returns: The value of the `s` parameter with which the object was constructed.

28.5.9.5.3 Class template `chi_squared_distribution`**[rand.dist.norm.chisq]**

A `chi_squared_distribution` random number distribution produces random numbers $x > 0$ distributed according to the probability density function in Formula 28.15.

$$p(x|n) = \frac{x^{(n/2)-1} \cdot e^{-x/2}}{\Gamma(n/2) \cdot 2^{n/2}} \quad (28.15)$$

```
namespace std {
    template<class RealType = double>
    class chi_squared_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        chi_squared_distribution() : chi_squared_distribution(1.0) {}
        explicit chi_squared_distribution(RealType n);
        explicit chi_squared_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const chi_squared_distribution& x, const chi_squared_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType n() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
            friend basic_ostream<charT, traits>&
                operator<<(basic_ostream<charT, traits>& os, const chi_squared_distribution& x);
        template<class charT, class traits>
            friend basic_istream<charT, traits>&
                operator>>(basic_istream<charT, traits>& is, chi_squared_distribution& x);
    };
}
```

`explicit chi_squared_distribution(RealType n);`

Preconditions: $0 < n$.

Remarks: n corresponds to the parameter of the distribution.

`RealType n() const;`

Returns: The value of the n parameter with which the object was constructed.

28.5.9.5.4 Class template `cauchy_distribution`**[rand.dist.norm.cauchy]**

A `cauchy_distribution` random number distribution produces random numbers x distributed according to the probability density function in Formula 28.16.

$$p(x|a,b) = \left(\pi b \left(1 + \left(\frac{x-a}{b} \right)^2 \right) \right)^{-1} \quad (28.16)$$

```

namespace std {
    template<class RealType = double>
    class cauchy_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        cauchy_distribution() : cauchy_distribution(0.0) {}
        explicit cauchy_distribution(RealType a, RealType b = 1.0);
        explicit cauchy_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const cauchy_distribution& x, const cauchy_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType a() const;
        RealType b() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
            friend basic_ostream<charT, traits>&
                operator<<(basic_ostream<charT, traits>& os, const cauchy_distribution& x);
        template<class charT, class traits>
            friend basic_istream<charT, traits>&
                operator>>(basic_istream<charT, traits>& is, cauchy_distribution& x);
    };
}

```

explicit cauchy_distribution(RealType a, RealType b = 1.0);

Preconditions: $0 < b$.

Remarks: **a** and **b** correspond to the respective parameters of the distribution.

RealType a() const;

Returns: The value of the **a** parameter with which the object was constructed.

RealType b() const;

Returns: The value of the **b** parameter with which the object was constructed.

28.5.9.5.5 Class template fisher_f_distribution

[rand.dist.norm.f]

A **fisher_f_distribution** random number distribution produces random numbers $x \geq 0$ distributed according to the probability density function in Formula 28.17.

$$p(x|m,n) = \frac{\Gamma((m+n)/2)}{\Gamma(m/2)\Gamma(n/2)} \cdot \left(\frac{m}{n}\right)^{m/2} \cdot x^{(m/2)-1} \cdot \left(1 + \frac{mx}{n}\right)^{-(m+n)/2} \quad (28.17)$$

```

namespace std {
    template<class RealType = double>
    class fisher_f_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        fisher_f_distribution() : fisher_f_distribution(1.0) {}
        explicit fisher_f_distribution(RealType m, RealType n = 1.0);
        explicit fisher_f_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const fisher_f_distribution& x, const fisher_f_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType m() const;
        RealType n() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
            friend basic_ostream<charT, traits>&
                operator<<(basic_ostream<charT, traits>& os, const fisher_f_distribution& x);
        template<class charT, class traits>
            friend basic_istream<charT, traits>&
                operator>>(basic_istream<charT, traits>& is, fisher_f_distribution& x);
    };
}

```

explicit fisher_f_distribution(RealType m, RealType n = 1);

Preconditions: $0 < m$ and $0 < n$.

Remarks: m and n correspond to the respective parameters of the distribution.

RealType m() const;

Returns: The value of the m parameter with which the object was constructed.

RealType n() const;

Returns: The value of the n parameter with which the object was constructed.

28.5.9.5.6 Class template student_t_distribution

[rand.dist.norm.t]

A student_t_distribution random number distribution produces random numbers x distributed according to the probability density function in Formula 28.18.

$$p(x|n) = \frac{1}{\sqrt{n\pi}} \cdot \frac{\Gamma((n+1)/2)}{\Gamma(n/2)} \cdot \left(1 + \frac{x^2}{n}\right)^{-(n+1)/2} \quad (28.18)$$

```

namespace std {
    template<class RealType = double>
    class student_t_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        student_t_distribution() : student_t_distribution(1.0) {}
        explicit student_t_distribution(RealType n);
        explicit student_t_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const student_t_distribution& x, const student_t_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType n() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
            friend basic_ostream<charT, traits>&
                operator<<(basic_ostream<charT, traits>& os, const student_t_distribution& x);
        template<class charT, class traits>
            friend basic_istream<charT, traits>&
                operator>>(basic_istream<charT, traits>& is, student_t_distribution& x);
    };
}

explicit student_t_distribution(RealType n);

```

Preconditions: $0 < n$.

Remarks: n corresponds to the parameter of the distribution.

RealType n() const;

Returns: The value of the n parameter with which the object was constructed.

28.5.9.6 Sampling distributions

[rand.dist.samp]

28.5.9.6.1 Class template discrete_distribution

[rand.dist.samp.discrete]

A `discrete_distribution` random number distribution produces random integers i , $0 \leq i < n$, distributed according to the discrete probability function in Formula 28.19.

$$P(i | p_0, \dots, p_{n-1}) = p_i \quad (28.19)$$

Unless specified otherwise, the distribution parameters are calculated as: $p_k = w_k/S$ for $k = 0, \dots, n-1$, in which the values w_k , commonly known as the *weights*, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold: $0 < S = w_0 + \dots + w_{n-1}$.

```

namespace std {
    template<class IntType = int>
    class discrete_distribution {
    public:
        // types
        using result_type = IntType;
        using param_type = unspecified;

        // constructor and reset functions
        discrete_distribution();
        template<class InputIterator>
            discrete_distribution(InputIterator firstW, InputIterator lastW);
        discrete_distribution(initializer_list<double> w1);
        template<class UnaryOperation>
            discrete_distribution(size_t nw, double xmin, double xmax, UnaryOperation fw);
        explicit discrete_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const discrete_distribution& x, const discrete_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        vector<double> probabilities() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
            friend basic_ostream<charT, traits>&
                operator<<(basic_ostream<charT, traits>& os, const discrete_distribution& x);
        template<class charT, class traits>
            friend basic_istream<charT, traits>&
                operator>>(basic_istream<charT, traits>& is, discrete_distribution& x);
    };
}

```

discrete_distribution();

Effects: Constructs a discrete_distribution object with $n = 1$ and $p_0 = 1$.

NOTE Such an object will always deliver the value 0.

```

template<class InputIterator>
discrete_distribution(InputIterator firstW, InputIterator lastW);

```

Mandates: `is_convertible_v<iterator_traits<InputIterator>::value_type, double>` is true.

Preconditions: InputIterator meets the Cpp17InputIterator requirements (25.3.5.3). If `firstW == lastW`, let $n = 1$ and $w_0 = 1$. Otherwise, `[firstW, lastW)` forms a sequence w of length $n > 0$.

Effects: Constructs a discrete_distribution object with probabilities given by the Formula 28.19.

```

discrete_distribution(initializer_list<double> w1);

```

Effects: Same as `discrete_distribution(w1.begin(), w1.end())`.

```

template<class UnaryOperation>
discrete_distribution(size_t nw, double xmin, double xmax, UnaryOperation fw);

```

Mandates: `is_invocable_r_v<double, UnaryOperation&, double>` is true.

Preconditions: If `nw = 0`, let $n = 1$, otherwise let $n = \text{nw}$. The relation $0 < \delta = (\text{xmax} - \text{xmin})/n$ holds.

Effects: Constructs a `discrete_distribution` object with probabilities given by the formula above, using the following values: If `nw = 0`, let $w_0 = 1$. Otherwise, let $w_k = \text{fw}(\text{xmin} + k \cdot \delta + \delta/2)$ for $k = 0, \dots, n-1$.

Complexity: The number of invocations of `fw` does not exceed n .

```
vector<double> probabilities() const;
```

Returns: A `vector<double>` whose `size` member returns n and whose `operator[]` member returns p_k when invoked with argument k for $k = 0, \dots, n-1$.

28.5.9.6.2 Class template `piecewise_constant_distribution` [rand.dist.samp.pconst]

A `piecewise_constant_distribution` random number distribution produces random numbers x , $b_0 \leq x < b_n$, uniformly distributed over each subinterval $[b_i, b_{i+1})$ according to the probability density function in Formula 28.20.

$$p(x | b_0, \dots, b_n, \rho_0, \dots, \rho_{n-1}) = \rho_i, \text{ for } b_i \leq x < b_{i+1} \quad (28.20)$$

The $n+1$ distribution parameters b_i , also known as this distribution's *interval boundaries*, shall satisfy the relation $b_i < b_{i+1}$ for $i = 0, \dots, n-1$. Unless specified otherwise, the remaining n distribution parameters are calculated as:

$$\rho_k = \frac{w_k}{S \cdot (b_{k+1} - b_k)} \text{ for } k = 0, \dots, n-1,$$

in which the values w_k , commonly known as the *weights*, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold: $0 < S = w_0 + \dots + w_{n-1}$.

```
namespace std {
    template<class RealType = double>
    class piecewise_constant_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        piecewise_constant_distribution();
        template<class InputIteratorB, class InputIteratorW>
            piecewise_constant_distribution(InputIteratorB firstB, InputIteratorB lastB,
                                           InputIteratorW firstW);
        template<class UnaryOperation>
            piecewise_constant_distribution(initializer_list<RealType> bl, UnaryOperation fw);
        template<class UnaryOperation>
            piecewise_constant_distribution(size_t nw, RealType xmin, RealType xmax,
                                           UnaryOperation fw);
        explicit piecewise_constant_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const piecewise_constant_distribution& x,
                              const piecewise_constant_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        vector<result_type> intervals() const;
        vector<result_type> densities() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;
    };
}
```

```

// inserters and extractors
template<class charT, class traits>
    friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const piecewise_constant_distribution& x);
template<class charT, class traits>
    friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, piecewise_constant_distribution& x);
};
}

piecewise_constant_distribution();

```

Effects: Constructs a `piecewise_constant_distribution` object with $n = 1$, $\rho_0 = 1$, $b_0 = 0$, and $b_1 = 1$.

```

template<class InputIteratorB, class InputIteratorW>
piecewise_constant_distribution(InputIteratorB firstB, InputIteratorB lastB,
                               InputIteratorW firstW);

```

Mandates: Both of

- `is_convertible_v<iterator_traits<InputIteratorB>::value_type, double>`
- `is_convertible_v<iterator_traits<InputIteratorW>::value_type, double>`

are true.

Preconditions: `InputIteratorB` and `InputIteratorW` each meet the *Cpp17InputIterator* requirements (25.3.5.3). If `firstB == lastB` or `++firstB == lastB`, let $n = 1$, $w_0 = 1$, $b_0 = 0$, and $b_1 = 1$. Otherwise, $[firstB, lastB)$ forms a sequence b of length $n + 1$, the length of the sequence w starting from `firstW` is at least n , and any w_k for $k \geq n$ are ignored by the distribution.

Effects: Constructs a `piecewise_constant_distribution` object with parameters as specified above.

```

template<class UnaryOperation>
piecewise_constant_distribution(initializer_list<RealType> bl, UnaryOperation fw);

```

Mandates: `is_invocable_r_v<double, UnaryOperation&, double>` is true.

Effects: Constructs a `piecewise_constant_distribution` object with parameters taken or calculated from the following values: If `bl.size() < 2`, let $n = 1$, $w_0 = 1$, $b_0 = 0$, and $b_1 = 1$. Otherwise, let $[bl.begin(), bl.end())$ form a sequence $b_0, \dots, b_n$, and let $w_k = fw((b_{k+1} + b_k)/2)$ for $k = 0, \dots, n - 1$.

Complexity: The number of invocations of `fw` does not exceed n .

```

template<class UnaryOperation>
piecewise_constant_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);

```

Mandates: `is_invocable_r_v<double, UnaryOperation&, double>` is true.

Preconditions: If `nw = 0`, let $n = 1$, otherwise let $n = nw$. The relation $0 < \delta = (xmax - xmin)/n$ holds.

Effects: Constructs a `piecewise_constant_distribution` object with parameters taken or calculated from the following values: Let $b_k = xmin + k \cdot \delta$ for $k = 0, \dots, n$, and $w_k = fw(b_k + \delta/2)$ for $k = 0, \dots, n - 1$.

Complexity: The number of invocations of `fw` does not exceed n .

```

vector<result_type> intervals() const;

```

Returns: A `vector<result_type>` whose `size` member returns $n + 1$ and whose `operator[]` member returns b_k when invoked with argument k for $k = 0, \dots, n$.

```

vector<result_type> densities() const;

```

Returns: A `vector<result_type>` whose `size` member returns n and whose `operator[]` member returns ρ_k when invoked with argument k for $k = 0, \dots, n - 1$.

28.5.9.6.3 Class template `piecewise_linear_distribution` [rand.dist.samp.plinear]

A `piecewise_linear_distribution` random number distribution produces random numbers x , $b_0 \leq x < b_n$, distributed over each subinterval $[b_i, b_{i+1})$ according to the probability density function in Formula 28.21.

$$p(x | b_0, \dots, b_n, \rho_0, \dots, \rho_n) = \rho_i \cdot \frac{b_{i+1} - x}{b_{i+1} - b_i} + \rho_{i+1} \cdot \frac{x - b_i}{b_{i+1} - b_i}, \text{ for } b_i \leq x < b_{i+1}. \quad (28.21)$$

The $n + 1$ distribution parameters b_i , also known as this distribution's *interval boundaries*, shall satisfy the relation $b_i < b_{i+1}$ for $i = 0, \dots, n - 1$. Unless specified otherwise, the remaining $n + 1$ distribution parameters are calculated as $\rho_k = w_k/S$ for $k = 0, \dots, n$, in which the values w_k , commonly known as the *weights at boundaries*, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold:

$$0 < S = \frac{1}{2} \cdot \sum_{k=0}^{n-1} (w_k + w_{k+1}) \cdot (b_{k+1} - b_k) .$$

```
namespace std {
    template<class RealType = double>
    class piecewise_linear_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        piecewise_linear_distribution();
        template<class InputIteratorB, class InputIteratorW>
            piecewise_linear_distribution(InputIteratorB firstB, InputIteratorB lastB,
                                         InputIteratorW firstW);
        template<class UnaryOperation>
            piecewise_linear_distribution(initializer_list<RealType> bl, UnaryOperation fw);
        template<class UnaryOperation>
            piecewise_linear_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);
        explicit piecewise_linear_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const piecewise_linear_distribution& x,
                              const piecewise_linear_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        vector<result_type> intervals() const;
        vector<result_type> densities() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
            operator<<(basic_ostream<charT, traits>& os, const piecewise_linear_distribution& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
            operator>>(basic_istream<charT, traits>& is, piecewise_linear_distribution& x);
    };
}
```

piecewise_linear_distribution();

Effects: Constructs a `piecewise_linear_distribution` object with $n = 1$, $\rho_0 = \rho_1 = 1$, $b_0 = 0$, and $b_1 = 1$.

```
template<class InputIteratorB, class InputIteratorW>
piecewise_linear_distribution(InputIteratorB firstB, InputIteratorB lastB,
                             InputIteratorW firstW);
```

Mandates: `is_invocable_r_v<double, UnaryOperation&, double>` is true.

Preconditions: `InputIteratorB` and `InputIteratorW` each meet the *Cpp17InputIterator* requirements (25.3.5.3). If `firstB == lastB` or `++firstB == lastB`, let $n = 1$, $\rho_0 = \rho_1 = 1$, $b_0 = 0$, and $b_1 = 1$. Otherwise, $[firstB, lastB)$ forms a sequence b of length $n + 1$, the length of the sequence w starting from `firstW` is at least $n + 1$, and any w_k for $k \geq n + 1$ are ignored by the distribution.

Effects: Constructs a `piecewise_linear_distribution` object with parameters as specified above.

```
template<class UnaryOperation>
piecewise_linear_distribution(initializer_list<RealType> bl, UnaryOperation fw);
```

Mandates: `is_invocable_r_v<double, UnaryOperation&, double>` is true.

Effects: Constructs a `piecewise_linear_distribution` object with parameters taken or calculated from the following values: If `bl.size() < 2`, let $n = 1$, $\rho_0 = \rho_1 = 1$, $b_0 = 0$, and $b_1 = 1$. Otherwise, let $[bl.begin(), bl.end())$ form a sequence $b_0, \dots, b_n$, and let $w_k = fw(b_k)$ for $k = 0, \dots, n$.

Complexity: The number of invocations of `fw` does not exceed $n + 1$.

```
template<class UnaryOperation>
piecewise_linear_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);
```

Mandates: `is_invocable_r_v<double, UnaryOperation&, double>` is true.

Preconditions: If `nw = 0`, let $n = 1$, otherwise let $n = nw$. The relation $0 < \delta = (xmax - xmin)/n$ holds.

Effects: Constructs a `piecewise_linear_distribution` object with parameters taken or calculated from the following values: Let $b_k = xmin + k \cdot \delta$ for $k = 0, \dots, n$, and $w_k = fw(b_k)$ for $k = 0, \dots, n$.

Complexity: The number of invocations of `fw` does not exceed $n + 1$.

```
vector<result_type> intervals() const;
```

Returns: A `vector<result_type>` whose `size` member returns $n + 1$ and whose `operator[]` member returns b_k when invoked with argument k for $k = 0, \dots, n$.

```
vector<result_type> densities() const;
```

Returns: A `vector<result_type>` whose `size` member returns n and whose `operator[]` member returns ρ_k when invoked with argument k for $k = 0, \dots, n$.

28.5.10 Low-quality random number generation

[c.math.rand]

NOTE 1 The header `<cstdlib>` (17.2.2) declares the functions described in this subclause.

```
int rand();
void srand(unsigned int seed);
```

Effects: The `rand` and `srand` functions have the semantics specified in the C standard library.

Remarks: The implementation may specify that particular library functions may call `rand`. It is implementation-defined whether the `rand` function may introduce data races (16.4.6.10).

NOTE 2 The other random number generation facilities in this document (28.5) are often preferable to `rand`, because `rand`'s underlying algorithm is unspecified. Use of `rand` therefore continues to be non-portable, with unpredictable and oft-questionable quality and performance.

See also ISO/IEC 9899:2018, 7.22.2.

28.6 Numeric arrays

[numarray]

28.6.1 Header `<valarray>` synopsis

[valarray.syn]

```
#include <initializer_list> // see 17.10.2
```

```
namespace std {
    template<class T> class valarray; // An array of type T
    class slice; // a BLAS-like slice out of an array
    template<class T> class slice_array;
```

1427

1428

```

template<class T> valarray<T> pow(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> pow(const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> pow(const typename valarray<T>::value_type&, const valarray<T>&);

template<class T> valarray<T> sin (const valarray<T>&);
template<class T> valarray<T> sinh (const valarray<T>&);
template<class T> valarray<T> sqrt (const valarray<T>&);
template<class T> valarray<T> tan (const valarray<T>&);
template<class T> valarray<T> tanh (const valarray<T>&);

template<class T> unspecified1 begin(valarray<T>& v);
template<class T> unspecified2 begin(const valarray<T>& v);
template<class T> unspecified1 end(valarray<T>& v);
template<class T> unspecified2 end(const valarray<T>& v);
}

```

The header `<valarray>` defines five class templates (`valarray`, `slice_array`, `gslice_array`, `mask_array`, and `indirect_array`), two classes (`slice` and `gslice`), and a series of related function templates for representing and manipulating arrays of values.

The `valarray` array classes are defined to be free of certain forms of aliasing, thus allowing operations on these classes to be optimized.

Any function returning a `valarray<T>` is permitted to return an object of another type, provided all the `const` member functions of `valarray<T>` are also applicable to this type. This return type shall not add more than two levels of template nesting over the most deeply nested argument type.²³²

Implementations introducing such replacement types shall provide additional functions and operators as follows:

- for every function taking a `const valarray<T>&` other than `begin` and `end` (28.6.10), identical functions taking the replacement types shall be added;
- for every function taking two `const valarray<T>&` arguments, identical functions taking every combination of `const valarray<T>&` and replacement types shall be added.

In particular, an implementation shall allow a `valarray<T>` to be constructed from such replacement types and shall allow assignments and compound assignments of such types to `valarray<T>`, `slice_array<T>`, `gslice_array<T>`, `mask_array<T>` and `indirect_array<T>` objects.

These library functions are permitted to throw a `bad_alloc` (17.6.4.1) exception if there are not sufficient resources available to carry out the operation. Note that the exception is not mandated.

28.6.2 Class template `valarray`

[template.valarray]

28.6.2.1 Overview

[template.valarray.overview]

```

namespace std {
    template<class T> class valarray {
    public:
        using value_type = T;

        // 28.6.2.2, construct/destroy
        valarray();
        explicit valarray(size_t);
        valarray(const T&, size_t);
        valarray(const T*, size_t);
        valarray(const valarray&);
        valarray(valarray&&) noexcept;
        valarray(const slice_array<T>&);
        valarray(const gslice_array<T>&);
        valarray(const mask_array<T>&);
        valarray(const indirect_array<T>&);
        valarray(initializer_list<T>);
        ~valarray();
    };
}

```

232) Annex B recommends a minimum number of recursively nested template instantiations. This requirement thus indirectly suggests a minimum allowable complexity for `valarray` expressions.

```

// 28.6.2.3, assignment
valarray& operator=(const valarray&);
valarray& operator=(valarray&&) noexcept;
valarray& operator=(initializer_list<T>);
valarray& operator=(const T&);
valarray& operator=(const slice_array<T>&);
valarray& operator=(const gslice_array<T>&);
valarray& operator=(const mask_array<T>&);
valarray& operator=(const indirect_array<T>&);

// 28.6.2.4, element access
const T&      operator[](size_t) const;
T&           operator[](size_t);

// 28.6.2.5, subset operations
valarray      operator[](slice) const;
slice_array<T> operator[](slice);
valarray      operator[](const gslice&) const;
gslice_array<T> operator[](const gslice&);
valarray      operator[](const valarray<bool>&) const;
mask_array<T> operator[](const valarray<bool>&);
valarray      operator[](const valarray<size_t>&) const;
indirect_array<T> operator[](const valarray<size_t>&);

// 28.6.2.6, unary operators
valarray operator+() const;
valarray operator-() const;
valarray operator~() const;
valarray<bool> operator!() const;

// 28.6.2.7, compound assignment
valarray& operator*= (const T&);
valarray& operator/= (const T&);
valarray& operator%= (const T&);
valarray& operator+= (const T&);
valarray& operator-= (const T&);
valarray& operator^= (const T&);
valarray& operator&= (const T&);
valarray& operator|= (const T&);
valarray& operator<=<= (const T&);
valarray& operator>>= (const T&);

valarray& operator*= (const valarray&);
valarray& operator/= (const valarray&);
valarray& operator%= (const valarray&);
valarray& operator+= (const valarray&);
valarray& operator-= (const valarray&);
valarray& operator^= (const valarray&);
valarray& operator&= (const valarray&);
valarray& operator|= (const valarray&);
valarray& operator<=<= (const valarray&);
valarray& operator>>= (const valarray&);

// 28.6.2.8, member functions
void swap(valarray&) noexcept;

size_t size() const;

T sum() const;
T min() const;
T max() const;

valarray shift (int) const;
valarray cshift(int) const;

```

```

    valarray apply(T func(T)) const;
    valarray apply(T func(const T&)) const;
    void resize(size_t sz, T c = T());
};

template<class T, size_t cnt> valarray(const T(&)[cnt], size_t) -> valarray<T>;
}

```

The class template `valarray<T>` is a one-dimensional smart array, with elements numbered sequentially from zero. It is a representation of the mathematical concept of an ordered set of values. For convenience, an object of type `valarray<T>` is referred to as an “array” throughout the remainder of 28.6. The illusion of higher dimensionality may be produced by the familiar idiom of computed indices, together with the powerful subsetting capabilities provided by the generalized subscript operators.²³³

28.6.2.2 Constructors

[`valarray.cons`]

```
valarray();
```

Effects: Constructs a `valarray` that has zero length.²³⁴

```
explicit valarray(size_t n);
```

Effects: Constructs a `valarray` that has length `n`. Each element of the array is value-initialized (9.4).

```
valarray(const T& v, size_t n);
```

Effects: Constructs a `valarray` that has length `n`. Each element of the array is initialized with `v`.

```
valarray(const T* p, size_t n);
```

Preconditions: `[p, p + n)` is a valid range.

Effects: Constructs a `valarray` that has length `n`. The values of the elements of the array are initialized with the first `n` values pointed to by the first argument.²³⁵

```
valarray(const valarray& v);
```

Effects: Constructs a `valarray` that has the same length as `v`. The elements are initialized with the values of the corresponding elements of `v`.²³⁶

```
valarray(valarray&& v) noexcept;
```

Effects: Constructs a `valarray` that has the same length as `v`. The elements are initialized with the values of the corresponding elements of `v`.

Complexity: Constant.

```
valarray(initializer_list<T> il);
```

Effects: Equivalent to `valarray(il.begin(), il.size())`.

```
valarray(const slice_array<T>&);
```

```
valarray(const gslice_array<T>&);
```

```
valarray(const mask_array<T>&);
```

```
valarray(const indirect_array<T>&);
```

These conversion constructors convert one of the four reference templates to a `valarray`.

```
~valarray();
```

Effects: The destructor is applied to every element of `*this`; an implementation may return all allocated memory.

233) The intent is to specify an array template that has the minimum functionality necessary to address aliasing ambiguities and the proliferation of temporary objects. Thus, the `valarray` template is neither a matrix class nor a field class. However, it is a very useful building block for designing such classes.

234) This default constructor is essential, since arrays of `valarray` can be useful. After initialization, the length of an empty array can be increased with the `resize` member function.

235) This constructor is the preferred method for converting a C array to a `valarray` object.

236) This copy constructor creates a distinct array rather than an alias. Implementations in which arrays share storage are permitted, but they would need to implement a copy-on-reference mechanism to ensure that arrays are conceptually distinct.

28.6.2.3 Assignment**[valarray.assign]**

```
valarray& operator=(const valarray& v);
```

Effects: Each element of the ***this** array is assigned the value of the corresponding element of **v**. If the length of **v** is not equal to the length of ***this**, resizes ***this** to make the two arrays the same length, as if by calling **resize(v.size())**, before performing the assignment.

Postconditions: **size() == v.size()**.

Returns: ***this**.

```
valarray& operator=(valarray&& v) noexcept;
```

Effects: ***this** obtains the value of **v**. The value of **v** after the assignment is not specified.

Returns: ***this**.

Complexity: Linear.

```
valarray& operator=(initializer_list<T> il);
```

Effects: Equivalent to: **return *this = valarray(il);**

```
valarray& operator=(const T& v);
```

Effects: Assigns **v** to each element of ***this**.

Returns: ***this**.

```
valarray& operator=(const slice_array<T>&);
```

```
valarray& operator=(const gslice_array<T>&);
```

```
valarray& operator=(const mask_array<T>&);
```

```
valarray& operator=(const indirect_array<T>&);
```

Preconditions: The length of the array to which the argument refers equals **size()**. The value of an element in the left-hand side of a **valarray** assignment operator does not depend on the value of another element in that left-hand side.

These operators allow the results of a generalized subscripting operation to be assigned directly to a **valarray**.

28.6.2.4 Element access**[valarray.access]**

```
const T& operator[](size_t n) const;
```

```
T& operator[](size_t n);
```

Preconditions: **n < size()** is true.

Returns: A reference to the corresponding element of the array.

NOTE 1 The expression **(a[i] = q, a[i]) == q** evaluates to **true** for any non-constant **valarray<T> a**, any **T q**, and for any **size_t i** such that the value of **i** is less than the length of **a**.

Remarks: The expression **addressof(a[i+j]) == addressof(a[i]) + j** evaluates to **true** for all **size_t i** and **size_t j** such that **i+j < a.size()**.

The expression **addressof(a[i]) != addressof(b[j])** evaluates to **true** for any two arrays **a** and **b** and for any **size_t i** and **size_t j** such that **i < a.size()** and **j < b.size()**.

NOTE 2 This property indicates an absence of aliasing and can be used to advantage by optimizing compilers. Compilers can take advantage of inlining, constant propagation, loop fusion, tracking of pointers obtained from **operator new**, and other techniques to generate efficient **valarrays**.

The reference returned by the subscript operator for an array shall be valid until the member function **resize(size_t, T)** (28.6.2.8) is called for that array or until the lifetime of that array ends, whichever happens first.

28.6.2.5 Subset operations**[valarray.sub]**

The member **operator[]** is overloaded to provide several ways to select sequences of elements from among those controlled by ***this**. Each of these operations returns a subset of the array. The **const**-qualified versions return this subset as a new **valarray** object. The non-**const** versions return a class template object which has reference semantics to the original array, working in conjunction with various overloads of **operator=**

and other assigning operators to allow selective replacement (slicing) of the controlled sequence. In each case the selected element(s) shall exist.

`valarray operator[](slice slicearr) const;`

Returns: A `valarray` containing those elements of the controlled sequence designated by `slicearr`.

EXAMPLE 1

```
const valarray<char> v0("abcdefghijklmnop", 16);
// v0[slice(2, 5, 3)] returns valarray<char>("cfilo", 5)
```

`slice_array<T> operator[](slice slicearr);`

Returns: An object that holds references to elements of the controlled sequence selected by `slicearr`.

EXAMPLE 2

```
valarray<char> v0("abcdefghijklmnop", 16);
valarray<char> v1("ABCDE", 5);
v0[slice(2, 5, 3)] = v1;
// v0 == valarray<char>("abAdeBghCjkdMnEp", 16);
```

`valarray operator[](const gslice& gslicearr) const;`

Returns: A `valarray` containing those elements of the controlled sequence designated by `gslicearr`.

EXAMPLE 3

```
const valarray<char> v0("abcdefghijklmnop", 16);
const size_t lv[] = { 2, 3 };
const size_t dv[] = { 7, 2 };
const valarray<size_t> len(lv, 2), str(dv, 2);
// v0[gslice(3, len, str)] returns
// valarray<char>("dfhkmo", 6)
```

`gslice_array<T> operator[](const gslice& gslicearr);`

Returns: An object that holds references to elements of the controlled sequence selected by `gslicearr`.

EXAMPLE 4

```
valarray<char> v0("abcdefghijklmnop", 16);
valarray<char> v1("ABCDEF", 6);
const size_t lv[] = { 2, 3 };
const size_t dv[] = { 7, 2 };
const valarray<size_t> len(lv, 2), str(dv, 2);
v0[gslice(3, len, str)] = v1;
// v0 == valarray<char>("abcAeBgCijDlEnFp", 16)
```

`valarray operator[](const valarray<bool>& boolarr) const;`

Returns: A `valarray` containing those elements of the controlled sequence designated by `boolarr`.

EXAMPLE 5

```
const valarray<char> v0("abcdefghijklmnop", 16);
const bool vb[] = { false, false, true, true, false, true };
// v0[valarray<bool>(vb, 6)] returns
// valarray<char>("cdf", 3)
```

`mask_array<T> operator[](const valarray<bool>& boolarr);`

Returns: An object that holds references to elements of the controlled sequence selected by `boolarr`.

EXAMPLE 6

```
valarray<char> v0("abcdefghijklmnop", 16);
valarray<char> v1("ABC", 3);
const bool vb[] = { false, false, true, true, false, true };
v0[valarray<bool>(vb, 6)] = v1;
// v0 == valarray<char>("abABeCghijklmnop", 16)
```

`valarray operator[](const valarray<size_t>& indarr) const;`

Returns: A `valarray` containing those elements of the controlled sequence designated by `indarr`.

EXAMPLE 7

```
const valarray<char> v0("abcdefghijklmnp", 16);
const size_t vi[] = { 7, 5, 2, 3, 8 };
// v0[valarray<size_t>(vi, 5)] returns
// valarray<char>("hfcdi", 5)
```

```
indirect_array<T> operator[](const valarray<size_t>& indarr);
```

Returns: An object that holds references to elements of the controlled sequence selected by `indarr`.

EXAMPLE 8

```
valarray<char> v0("abcdefghijklmnp", 16);
valarray<char> v1("ABCDE", 5);
const size_t vi[] = { 7, 5, 2, 3, 8 };
v0[valarray<size_t>(vi, 5)] = v1;
// v0 == valarray<char>("abCDeBgAEjklmnp", 16)
```

28.6.2.6 Unary operators

[valarray.unary]

```
valarray operator+() const;
valarray operator-() const;
valarray operator~() const;
valarray<bool> operator!() const;
```

Mandates: The indicated operator can be applied to operands of type `T` and returns a value of type `T` (`bool` for `operator!`) or which may be unambiguously implicitly converted to type `T` (`bool` for `operator!`).

Returns: A `valarray` whose length is `size()`. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array.

28.6.2.7 Compound assignment

[valarray.cassign]

```
valarray& operator*= (const valarray& v);
valarray& operator/= (const valarray& v);
valarray& operator%= (const valarray& v);
valarray& operator+= (const valarray& v);
valarray& operator-= (const valarray& v);
valarray& operator^= (const valarray& v);
valarray& operator&= (const valarray& v);
valarray& operator|= (const valarray& v);
valarray& operator<<= (const valarray& v);
valarray& operator>>= (const valarray& v);
```

Mandates: The indicated operator can be applied to two operands of type `T`.

Preconditions: `size() == v.size()` is true.

The value of an element in the left-hand side of a `valarray` compound assignment operator does not depend on the value of another element in that left hand side.

Effects: Each of these operators performs the indicated operation on each of the elements of `*this` and the corresponding element of `v`.

Returns: `*this`.

Remarks: The appearance of an array on the left-hand side of a compound assignment does not invalidate references or pointers.

```
valarray& operator*= (const T& v);
valarray& operator/= (const T& v);
valarray& operator%= (const T& v);
valarray& operator+= (const T& v);
valarray& operator-= (const T& v);
valarray& operator^= (const T& v);
valarray& operator&= (const T& v);
valarray& operator|= (const T& v);
valarray& operator<<= (const T& v);
```

```
valarray& operator>>=(const T& v);
```

Mandates: The indicated operator can be applied to two operands of type T.

Effects: Each of these operators applies the indicated operation to each element of **this* and v.

Returns: **this*

Remarks: The appearance of an array on the left-hand side of a compound assignment does not invalidate references or pointers to the elements of the array.

28.6.2.8 Member functions

[valarray.members]

```
void swap(valarray& v) noexcept;
```

Effects: **this* obtains the value of v. v obtains the value of **this*.

Complexity: Constant.

```
size_t size() const;
```

Returns: The number of elements in the array.

Complexity: Constant time.

```
T sum() const;
```

Mandates: *operator+=* can be applied to operands of type T.

Preconditions: *size()* > 0 is true.

Returns: The sum of all the elements of the array. If the array has length 1, returns the value of element 0. Otherwise, the returned value is calculated by applying *operator+=* to a copy of an element of the array and all other elements of the array in an unspecified order.

```
T min() const;
```

Preconditions: *size()* > 0 is true.

Returns: The minimum value contained in **this*. For an array of length 1, the value of element 0 is returned. For all other array lengths, the determination is made using *operator<*.

```
T max() const;
```

Preconditions: *size()* > 0 is true.

Returns: The maximum value contained in **this*. For an array of length 1, the value of element 0 is returned. For all other array lengths, the determination is made using *operator<*.

```
valarray shift(int n) const;
```

Returns: A valarray of length *size()*, each of whose elements *I* is *(*this)[I + n]* if *I + n* is non-negative and less than *size()*, otherwise T().

NOTE If element zero is taken as the leftmost element, a positive value of *n* shifts the elements left *n* places, with zero fill.

EXAMPLE If the argument has the value -2 , the first two elements of the result will be value-initialized (9.4); the third element of the result will be assigned the value of the first element of **this*; etc.

```
valarray cshift(int n) const;
```

Returns: A valarray of length *size()* that is a circular shift of **this*. If element zero is taken as the leftmost element, a non-negative value of *n* shifts the elements circularly left *n* places and a negative value of *n* shifts the elements circularly right $-n$ places.

```
valarray apply(T func(T)) const;
```

```
valarray apply(T func(const T&)) const;
```

Returns: A valarray whose length is *size()*. Each element of the returned array is assigned the value returned by applying the argument function to the corresponding element of **this*.

```
void resize(size_t sz, T c = T());
```

Effects: Changes the length of the **this* array to *sz* and then assigns to each element the value of the second argument. Resizing invalidates all pointers and references to elements in the array.

28.6.3 valarray non-member operations

[valarray.nonmembers]

28.6.3.1 Binary operators

[valarray.binary]

```

template<class T> valarray<T> operator* (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator/ (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator% (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator+ (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator- (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator^ (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator& (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator| (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator<< (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator>> (const valarray<T>&, const valarray<T>&);

```

Mandates: The indicated operator can be applied to operands of type T and returns a value of type T or which can be unambiguously implicitly converted to T.

Preconditions: The argument arrays have the same length.

Returns: A valarray whose length is equal to the lengths of the argument arrays. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding elements of the argument arrays.

```

template<class T> valarray<T> operator* (const valarray<T>&,
                                         const typename valarray<T>::value_type&);
template<class T> valarray<T> operator* (const typename valarray<T>::value_type&,
                                         const valarray<T>&);
template<class T> valarray<T> operator/ (const valarray<T>&,
                                         const typename valarray<T>::value_type&);
template<class T> valarray<T> operator/ (const typename valarray<T>::value_type&,
                                         const valarray<T>&);
template<class T> valarray<T> operator% (const valarray<T>&,
                                         const typename valarray<T>::value_type&);
template<class T> valarray<T> operator% (const typename valarray<T>::value_type&,
                                         const valarray<T>&);
template<class T> valarray<T> operator+ (const valarray<T>&,
                                         const typename valarray<T>::value_type&);
template<class T> valarray<T> operator+ (const typename valarray<T>::value_type&,
                                         const valarray<T>&);
template<class T> valarray<T> operator- (const valarray<T>&,
                                         const typename valarray<T>::value_type&);
template<class T> valarray<T> operator- (const typename valarray<T>::value_type&,
                                         const valarray<T>&);
template<class T> valarray<T> operator^ (const valarray<T>&,
                                         const typename valarray<T>::value_type&);
template<class T> valarray<T> operator^ (const typename valarray<T>::value_type&,
                                         const valarray<T>&);
template<class T> valarray<T> operator& (const valarray<T>&,
                                         const typename valarray<T>::value_type&);
template<class T> valarray<T> operator& (const typename valarray<T>::value_type&,
                                         const valarray<T>&);
template<class T> valarray<T> operator| (const valarray<T>&,
                                         const typename valarray<T>::value_type&);
template<class T> valarray<T> operator| (const typename valarray<T>::value_type&,
                                         const valarray<T>&);
template<class T> valarray<T> operator<< (const valarray<T>&,
                                         const typename valarray<T>::value_type&);
template<class T> valarray<T> operator<< (const typename valarray<T>::value_type&,
                                         const valarray<T>&);
template<class T> valarray<T> operator>> (const valarray<T>&,
                                         const typename valarray<T>::value_type&);
template<class T> valarray<T> operator>> (const typename valarray<T>::value_type&,
                                         const valarray<T>&);

```

Mandates: The indicated operator can be applied to operands of type T and returns a value of type T or which can be unambiguously implicitly converted to T.

Returns: A `valarray` whose length is equal to the length of the array argument. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array argument and the non-array argument.

28.6.3.2 Logical operators

[`valarray.comparison`]

```
template<class T> valarray<bool> operator==(const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator!=(const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator< (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator> (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator<=(const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator>=(const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator&&(const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator|| (const valarray<T>&, const valarray<T>&);
```

Mandates: The indicated operator can be applied to operands of type `T` and returns a value of type `bool` or which can be unambiguously implicitly converted to `bool`.

Preconditions: The two array arguments have the same length.

Returns: A `valarray<bool>` whose length is equal to the length of the array arguments. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding elements of the argument arrays.

```
template<class T> valarray<bool> operator==(const valarray<T>&,
                                             const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator==(const typename valarray<T>::value_type&,
                                             const valarray<T>&);
template<class T> valarray<bool> operator!=(const valarray<T>&,
                                             const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator!=(const typename valarray<T>::value_type&,
                                             const valarray<T>&);
template<class T> valarray<bool> operator< (const valarray<T>&,
                                             const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator< (const typename valarray<T>::value_type&,
                                             const valarray<T>&);
template<class T> valarray<bool> operator> (const valarray<T>&,
                                             const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator> (const typename valarray<T>::value_type&,
                                             const valarray<T>&);
template<class T> valarray<bool> operator<=(const valarray<T>&,
                                             const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator<=(const typename valarray<T>::value_type&,
                                             const valarray<T>&);
template<class T> valarray<bool> operator>=(const valarray<T>&,
                                             const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator>=(const typename valarray<T>::value_type&,
                                             const valarray<T>&);
template<class T> valarray<bool> operator&&(const valarray<T>&,
                                             const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator&&(const typename valarray<T>::value_type&,
                                             const valarray<T>&);
template<class T> valarray<bool> operator|| (const valarray<T>&,
                                             const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator|| (const typename valarray<T>::value_type&,
                                             const valarray<T>&);
```

Mandates: The indicated operator can be applied to operands of type `T` and returns a value of type `bool` or which can be unambiguously implicitly converted to `bool`.

Returns: A `valarray<bool>` whose length is equal to the length of the array argument. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array and the non-array argument.

28.6.3.3 Transcendentals

[`valarray.transcend`]

```
template<class T> valarray<T> abs (const valarray<T>&);
```

```

template<class T> valarray<T> acos (const valarray<T>&);
template<class T> valarray<T> asin (const valarray<T>&);
template<class T> valarray<T> atan (const valarray<T>&);
template<class T> valarray<T> atan2(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> atan2(const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> atan2(const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> cos (const valarray<T>&);
template<class T> valarray<T> cosh (const valarray<T>&);
template<class T> valarray<T> exp (const valarray<T>&);
template<class T> valarray<T> log (const valarray<T>&);
template<class T> valarray<T> log10(const valarray<T>&);
template<class T> valarray<T> pow (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> pow (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> pow (const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> sin (const valarray<T>&);
template<class T> valarray<T> sinh (const valarray<T>&);
template<class T> valarray<T> sqrt (const valarray<T>&);
template<class T> valarray<T> tan (const valarray<T>&);
template<class T> valarray<T> tanh (const valarray<T>&);

```

Mandates: A unique function with the indicated name can be applied (unqualified) to an operand of type T. This function returns a value of type T or which can be unambiguously implicitly converted to type T.

28.6.3.4 Specialized algorithms

[valarray.special]

```
template<class T> void swap(valarray<T>& x, valarray<T>& y) noexcept;
```

Effects: Equivalent to `x.swap(y)`.

28.6.4 Class slice

[class.slice]

28.6.4.1 Overview

[class.slice.overview]

```

namespace std {
    class slice {
    public:
        slice();
        slice(size_t, size_t, size_t);
        slice(const slice&);

        size_t start() const;
        size_t size() const;
        size_t stride() const;

        friend bool operator==(const slice& x, const slice& y);
    };
}

```

The `slice` class represents a BLAS-like slice from an array. Such a slice is specified by a starting index, a length, and a stride.²³⁷

28.6.4.2 Constructors

[cons.slice]

```

slice();
slice(size_t start, size_t length, size_t stride);

```

The default constructor is equivalent to `slice(0, 0, 0)`. A default constructor is provided only to permit the declaration of arrays of slices. The constructor with arguments for a slice takes a start, length, and stride parameter.

EXAMPLE `slice(3, 8, 2)` constructs a slice which selects elements 3, 5, 7, ..., 17 from an array.

²³⁷) BLAS stands for *Basic Linear Algebra Subprograms*. C++ programs can instantiate this class. See, for example, Dongarra, Du Croz, Duff, and Hammerling: *A set of Level 3 Basic Linear Algebra Subprograms*; Technical Report MCS-P1-0888, Argonne National Laboratory (USA), Mathematics and Computer Science Division, August, 1988.

28.6.4.3 Access functions

[slice.access]

```
size_t start() const;
size_t size() const;
size_t stride() const;
```

Returns: The start, length, or stride specified by a `slice` object.

Complexity: Constant time.

28.6.4.4 Operators

[slice.ops]

```
friend bool operator==(const slice& x, const slice& y);
```

Effects: Equivalent to:

```
return x.start() == y.start() && x.size() == y.size() && x.stride() == y.stride();
```

28.6.5 Class template `slice_array`

[template.slice.array]

28.6.5.1 Overview

[template.slice.array.overview]

```
namespace std {
    template<class T> class slice_array {
    public:
        using value_type = T;

        void operator= (const valarray<T>&) const;
        void operator*= (const valarray<T>&) const;
        void operator/= (const valarray<T>&) const;
        void operator%= (const valarray<T>&) const;
        void operator+= (const valarray<T>&) const;
        void operator-= (const valarray<T>&) const;
        void operator^= (const valarray<T>&) const;
        void operator&= (const valarray<T>&) const;
        void operator|= (const valarray<T>&) const;
        void operator<<= (const valarray<T>&) const;
        void operator>>= (const valarray<T>&) const;

        slice_array(const slice_array&);
        ~slice_array();
        const slice_array& operator=(const slice_array&) const;
        void operator=(const T&) const;

        slice_array() = delete; // as implied by declaring copy constructor above
    };
}
```

This template is a helper template used by the `slice` subscript operator

```
slice_array<T> valarray<T>::operator[](slice);
```

It has reference semantics to a subset of an array specified by a `slice` object.

EXAMPLE The expression `a[slice(1, 5, 3)] = b;` has the effect of assigning the elements of `b` to a slice of the elements in `a`. For the slice shown, the elements selected from `a` are 1, 4, ..., 13.

28.6.5.2 Assignment

[slice.arr.assign]

```
void operator=(const valarray<T>&) const;
const slice_array& operator=(const slice_array&) const;
```

These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the `valarray<T>` object to which the `slice_array` object refers.

28.6.5.3 Compound assignment

[slice.arr.comp.assign]

```
void operator*= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
```

```

void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<=<= (const valarray<T>&) const;
void operator>>= (const valarray<T>&) const;

```

These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the `valarray<T>` object to which the `slice_array` object refers.

28.6.5.4 Fill function

[`slice.arr.fill`]

```
void operator=(const T&) const;
```

This function has reference semantics, assigning the value of its argument to the elements of the `valarray<T>` object to which the `slice_array` object refers.

28.6.6 The `gslice` class

[`class.gslice`]

28.6.6.1 Overview

[`class.gslice.overview`]

```

namespace std {
    class gslice {
    public:
        gslice();
        gslice(size_t s, const valarray<size_t>& l, const valarray<size_t>& d);

        size_t      start() const;
        valarray<size_t> size() const;
        valarray<size_t> stride() const;
    };
}

```

This class represents a generalized slice out of an array. A `gslice` is defined by a starting offset (s), a set of lengths (l_j), and a set of strides (d_j). The number of lengths shall equal the number of strides.

A `gslice` represents a mapping from a set of indices (i_j), equal in number to the number of strides, to a single index k . It is useful for building multidimensional array classes using the `valarray` template, which is one-dimensional. The set of one-dimensional index values specified by a `gslice` are

$$k = s + \sum_j i_j d_j$$

where the multidimensional indices i_j range in value from 0 to $l_{ij} - 1$.

EXAMPLE 1 The `gslice` specification

```

start  = 3
length = {2, 4, 3}
stride = {19, 4, 1}

```

yields the sequence of one-dimensional indices

$$k = 3 + (0, 1) \times 19 + (0, 1, 2, 3) \times 4 + (0, 1, 2) \times 1$$

which are ordered as shown in the following table:

(i_0, i_1, i_2, k)	=
(0, 0, 0, 3),	
(0, 0, 1, 4),	
(0, 0, 2, 5),	
(0, 1, 0, 7),	
(0, 1, 1, 8),	
(0, 1, 2, 9),	
(0, 2, 0, 11),	
(0, 2, 1, 12),	
(0, 2, 2, 13),	
(0, 3, 0, 15),	
(0, 3, 1, 16),	

```
(0, 3, 2, 17),
(1, 0, 0, 22),
(1, 0, 1, 23),
...
(1, 3, 2, 36)
```

That is, the highest-ordered index turns fastest.

It is possible to have degenerate generalized slices in which an address is repeated.

EXAMPLE 2 If the stride parameters in the previous example are changed to {1, 1, 1}, the first few elements of the resulting sequence of indices will be

```
(0, 0, 0, 3),
(0, 0, 1, 4),
(0, 0, 2, 5),
(0, 1, 0, 4),
(0, 1, 1, 5),
(0, 1, 2, 6),
...
```

If a degenerate slice is used as the argument to the non-const version of `operator[]`(const `gslice&`), the behavior is undefined.

28.6.6.2 Constructors

[`gslice.cons`]

```
gslice();
gslice(size_t start, const valarray<size_t>& lengths,
       const valarray<size_t>& strides);
```

The default constructor is equivalent to `gslice(0, valarray<size_t>(), valarray<size_t>())`. The constructor with arguments builds a `gslice` based on a specification of start, lengths, and strides, as explained in the previous subclause.

28.6.6.3 Access functions

[`gslice.access`]

```
size_t      start() const;
valarray<size_t> size() const;
valarray<size_t> stride() const;
```

Returns: The representation of the start, lengths, or strides specified for the `gslice`.

Complexity: `start()` is constant time. `size()` and `stride()` are linear in the number of strides.

28.6.7 Class template `gslice_array`

[`template.gslice.array`]

28.6.7.1 Overview

[`template.gslice.array.overview`]

```
namespace std {
    template<class T> class gslice_array {
    public:
        using value_type = T;

        void operator= (const valarray<T>&) const;
        void operator*= (const valarray<T>&) const;
        void operator/= (const valarray<T>&) const;
        void operator%=(const valarray<T>&) const;
        void operator+=(const valarray<T>&) const;
        void operator-=(const valarray<T>&) const;
        void operator^=(const valarray<T>&) const;
        void operator&=(const valarray<T>&) const;
        void operator|=(const valarray<T>&) const;
        void operator<<=(const valarray<T>&) const;
        void operator>>=(const valarray<T>&) const;

        gslice_array(const gslice_array&);
        ~gslice_array();
        const gslice_array& operator=(const gslice_array&) const;
        void operator=(const T&) const;
```

```

    gslice_array() = delete;    // as implied by declaring copy constructor above
};
}

```

This template is a helper template used by the `gslice` subscript operator

```
gslice_array<T> valarray<T>::operator[](const gslice&);
```

It has reference semantics to a subset of an array specified by a `gslice` object. Thus, the expression `a[gslice(1, length, stride)] = b` has the effect of assigning the elements of `b` to a generalized slice of the elements in `a`.

28.6.7.2 Assignment

[gslice.array.assign]

```

void operator=(const valarray<T>&) const;
const gslice_array& operator=(const gslice_array&) const;

```

These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the `valarray<T>` object to which the `gslice_array` refers.

28.6.7.3 Compound assignment

[gslice.array.comp.assign]

```

void operator*=(const valarray<T>&) const;
void operator/=(const valarray<T>&) const;
void operator%=(const valarray<T>&) const;
void operator+=(const valarray<T>&) const;
void operator-=(const valarray<T>&) const;
void operator^=(const valarray<T>&) const;
void operator&=(const valarray<T>&) const;
void operator|=(const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

```

These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the `valarray<T>` object to which the `gslice_array` object refers.

28.6.7.4 Fill function

[gslice.array.fill]

```
void operator=(const T&) const;
```

This function has reference semantics, assigning the value of its argument to the elements of the `valarray<T>` object to which the `gslice_array` object refers.

28.6.8 Class template `mask_array`

[template.mask.array]

28.6.8.1 Overview

[template.mask.array.overview]

```

namespace std {
    template<class T> class mask_array {
    public:
        using value_type = T;

        void operator= (const valarray<T>&) const;
        void operator*= (const valarray<T>&) const;
        void operator/=(const valarray<T>&) const;
        void operator%=(const valarray<T>&) const;
        void operator+=(const valarray<T>&) const;
        void operator-=(const valarray<T>&) const;
        void operator^=(const valarray<T>&) const;
        void operator&=(const valarray<T>&) const;
        void operator|=(const valarray<T>&) const;
        void operator<<=(const valarray<T>&) const;
        void operator>>=(const valarray<T>&) const;

        mask_array(const mask_array&);
        ~mask_array();
        const mask_array& operator=(const mask_array&) const;
        void operator=(const T&) const;
    };
}

```

```

    mask_array() = delete;    // as implied by declaring copy constructor above
};
}

```

This template is a helper template used by the mask subscript operator:

```
mask_array<T> valarray<T>::operator[] (const valarray<bool>&);
```

It has reference semantics to a subset of an array specified by a boolean mask. Thus, the expression `a[mask] = b;` has the effect of assigning the elements of `b` to the masked elements in `a` (those for which the corresponding element in `mask` is true).

28.6.8.2 Assignment

[mask.array.assign]

```

void operator=(const valarray<T>&) const;
const mask_array& operator=(const mask_array&) const;

```

These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the `valarray<T>` object to which the `mask_array` object refers.

28.6.8.3 Compound assignment

[mask.array.comp.assign]

```

void operator*=(const valarray<T>&) const;
void operator/=(const valarray<T>&) const;
void operator%=(const valarray<T>&) const;
void operator+=(const valarray<T>&) const;
void operator-=(const valarray<T>&) const;
void operator^=(const valarray<T>&) const;
void operator&=(const valarray<T>&) const;
void operator|=(const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

```

These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the `valarray<T>` object to which the `mask_array` object refers.

28.6.8.4 Fill function

[mask.array.fill]

```
void operator=(const T&) const;
```

This function has reference semantics, assigning the value of its argument to the elements of the `valarray<T>` object to which the `mask_array` object refers.

28.6.9 Class template `indirect_array`

[template.indirect.array]

28.6.9.1 Overview

[template.indirect.array.overview]

```

namespace std {
    template<class T> class indirect_array {
    public:
        using value_type = T;

        void operator= (const valarray<T>&) const;
        void operator*=(const valarray<T>&) const;
        void operator/=(const valarray<T>&) const;
        void operator%=(const valarray<T>&) const;
        void operator+=(const valarray<T>&) const;
        void operator-=(const valarray<T>&) const;
        void operator^=(const valarray<T>&) const;
        void operator&=(const valarray<T>&) const;
        void operator|=(const valarray<T>&) const;
        void operator<<=(const valarray<T>&) const;
        void operator>>=(const valarray<T>&) const;

        indirect_array(const indirect_array&);
        ~indirect_array();
        const indirect_array& operator=(const indirect_array&) const;
        void operator=(const T&) const;
    };
}

```

```

    indirect_array() = delete; // as implied by declaring copy constructor above
};
}

```

This template is a helper template used by the indirect subscript operator

```
indirect_array<T> valarray<T>::operator[](const valarray<size_t>&);
```

It has reference semantics to a subset of an array specified by an `indirect_array`. Thus, the expression `a[indirect] = b;` has the effect of assigning the elements of `b` to the elements in `a` whose indices appear in `indirect`.

28.6.9.2 Assignment

[indirect.array.assign]

```

void operator=(const valarray<T>&) const;
const indirect_array& operator=(const indirect_array&) const;

```

These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the `valarray<T>` object to which it refers.

If the `indirect_array` specifies an element in the `valarray<T>` object to which it refers more than once, the behavior is undefined.

EXAMPLE

```

int addr[] = {2, 3, 1, 4, 4};
valarray<size_t> indirect(addr, 5);
valarray<double> a(0., 10), b(1., 5);
a[indirect] = b;

```

results in undefined behavior since element 4 is specified twice in the indirection.

28.6.9.3 Compound assignment

[indirect.array.comp.assign]

```

void operator*= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<= (const valarray<T>&) const;
void operator>>= (const valarray<T>&) const;

```

These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the `valarray<T>` object to which the `indirect_array` object refers.

If the `indirect_array` specifies an element in the `valarray<T>` object to which it refers more than once, the behavior is undefined.

28.6.9.4 Fill function

[indirect.array.fill]

```
void operator=(const T&) const;
```

This function has reference semantics, assigning the value of its argument to the elements of the `valarray<T>` object to which the `indirect_array` object refers.

28.6.10 valarray range access

[valarray.range]

In the `begin` and `end` function templates that follow, *unspecified1* is a type that meets the requirements of a mutable *Cpp17RandomAccessIterator* (25.3.5.7) and models *contiguous_iterator* (25.3.4.14), whose *value_type* is the template parameter `T` and whose *reference type* is `T&`. *unspecified2* is a type that meets the requirements of a constant *Cpp17RandomAccessIterator* and models *contiguous_iterator*, whose *value_type* is the template parameter `T` and whose *reference type* is `const T&`.

The iterators returned by `begin` and `end` for an array are guaranteed to be valid until the member function `resize(size_t, T)` (28.6.2.8) is called for that array or until the lifetime of that array ends, whichever happens first.

```
template<class T> unspecified1 begin(valarray<T>& v);
template<class T> unspecified2 begin(const valarray<T>& v);
```

Returns: An iterator referencing the first value in the array.

```
template<class T> unspecified1 end(valarray<T>& v);
template<class T> unspecified2 end(const valarray<T>& v);
```

Returns: An iterator referencing one past the last value in the array.

28.7 Mathematical functions for floating-point types

float      sph_neumannf(unsigned n, float x);
long double sph_neumannl(unsigned n, long double x);
}

```

The contents and meaning of the header `<cmath>` are the same as the C standard library header `<math.h>`, with the addition of a three-dimensional hypotenuse function (28.7.3), a linear interpolation function (28.7.4), and the mathematical special functions described in 28.7.6.

NOTE Several functions have additional overloads in this document, but they have the same behavior as in the C standard library (16.2).

For each function with at least one parameter of type *floating-point-type*, the implementation provides an overload for each cv-unqualified floating-point type (6.8.2) where all uses of *floating-point-type* in the function signature are replaced with that floating-point type.

For each function with at least one parameter of type *floating-point-type* other than `abs`, the implementation also provides additional overloads sufficient to ensure that, if every argument corresponding to a *floating-point-type* parameter has arithmetic type, then every such argument is effectively cast to the floating-point type with the greatest floating-point conversion rank and greatest floating-point conversion subrank among the types of all such arguments, where arguments of integer type are considered to have the same floating-point conversion rank as `double`. If no such floating-point type with the greatest rank and subrank exists, then overload resolution does not result in a usable candidate (12.2.1) from the overloads provided by the implementation.

An invocation of `nexttoward` is ill-formed if the argument corresponding to the *floating-point-type* parameter has extended floating-point type.

See also ISO/IEC 9899:2018, 7.12.

28.7.2 Absolute values

[c.math.abs]

NOTE 1 The headers `<cstdlib>` (17.2.2) and `<cmath>` (28.7.1) declare the functions described in this subclause.

```

constexpr int abs(int j);
constexpr long int abs(long int j);
constexpr long long int abs(long long int j);

```

Effects: These functions have the semantics specified in the C standard library for the functions `abs`, `labs`, and `llabs`, respectively.

Remarks: If `abs` is called with an argument of type `X` for which `is_unsigned_v<X>` is `true` and if `X` cannot be converted to `int` by integral promotion (7.3.7), the program is ill-formed.

NOTE 2 Allowing arguments that can be promoted to `int` provides compatibility with C.

```

constexpr floating-point-type abs(floating-point-type x);

```

Returns: The absolute value of `x`.

See also ISO/IEC 9899:2018, 7.12.7.2, 7.22.6.1.

28.7.3 Three-dimensional hypotenuse**[c.math.hypot3]**

floating-point-type hypot(*floating-point-type* x, *floating-point-type* y, *floating-point-type* z);

Returns: $\sqrt{x^2 + y^2 + z^2}$.

28.7.4 Linear interpolation**[c.math.lerp]**

constexpr *floating-point-type* lerp(*floating-point-type* a, *floating-point-type* b, *floating-point-type* t) noexcept;

Returns: $a + t(b - a)$.

Remarks: Let r be the value returned. If isfinite(a) && isfinite(b), then:

- If t == 0, then r == a.
- If t == 1, then r == b.
- If t >= 0 && t <= 1, then isfinite(r).
- If isfinite(t) && a == b, then r == a.
- If isfinite(t) || !isnan(t) && b-a != 0, then !isnan(r).

Let CMP(x,y) be 1 if x > y, -1 if x < y, and 0 otherwise. For any t1 and t2, the product of CMP(lerp(a, b, t2), lerp(a, b, t1)), CMP(t2, t1), and CMP(b, a) is non-negative.

28.7.5 Classification / comparison functions**[c.math.fpclass]**

The classification / comparison functions behave the same as the C macros with the corresponding names defined in the C standard library.

See also ISO/IEC 9899:2018, 7.12.3, 7.12.4.

28.7.6 Mathematical special functions**[sf.cmath]****28.7.6.1 General****[sf.cmath.general]**

If any argument value to any of the functions specified in 28.7.6 is a NaN (Not a Number), the function shall return a NaN but it shall not report a domain error. Otherwise, the function shall report a domain error for just those argument values for which:

- the function description's Returns: element explicitly specifies a domain and those argument values fall outside the specified domain, or
- the corresponding mathematical function value has a nonzero imaginary component, or
- the corresponding mathematical function is not mathematically defined.²³⁸

Unless otherwise specified, each function is defined for all finite values, for negative infinity, and for positive infinity.

28.7.6.2 Associated Laguerre polynomials**[sf.cmath.assoc.laguerre]**

floating-point-type assoc_laguerre(unsigned n, unsigned m, *floating-point-type* x);

float assoc_laguerref(unsigned n, unsigned m, float x);

long double assoc_laguerrel(unsigned n, unsigned m, long double x);

Effects: These functions compute the associated Laguerre polynomials of their respective arguments n, m, and x.

Returns: $L_n^m(x)$, where L_n^m is given by Formula 28.22, n is n, m is m, and x is x.

$$L_n^m(x) = (-1)^m \frac{d^m}{dx^m} L_{n+m}(x), \quad \text{for } x \geq 0 \quad (28.22)$$

Remarks: The effect of calling each of these functions is implementation-defined if n >= 128 or if m >= 128.

²³⁸ A mathematical function is mathematically defined for a given set of argument values (a) if it is explicitly defined for that set of argument values, or (b) if its limiting value exists and does not depend on the direction of approach.

28.7.6.3 Associated Legendre functions**[sf.cmath.assoc.legendre]**

floating-point-type `assoc_legendre(unsigned l, unsigned m, floating-point-type x);`
 float `assoc_legendref(unsigned l, unsigned m, float x);`
 long double `assoc_legendrel(unsigned l, unsigned m, long double x);`

Effects: These functions compute the associated Legendre functions of their respective arguments l , m , and x .

Returns: $P_\ell^m(x)$, where P_ℓ^m is given by Formula 28.23, l is l , m is m , and x is x .

$$P_\ell^m(x) = (1 - x^2)^{m/2} \frac{d^m}{dx^m} P_\ell(x), \quad \text{for } |x| \leq 1 \quad (28.23)$$

Remarks: The effect of calling each of these functions is implementation-defined if $l \geq 128$.

28.7.6.4 Beta function**[sf.cmath.beta]**

floating-point-type `beta(floating-point-type x, floating-point-type y);`
 float `betaf(float x, float y);`
 long double `betal(long double x, long double y);`

Effects: These functions compute the beta function of their respective arguments x and y .

Returns: $B(x, y)$, where B is given by Formula 28.24, x is x and y is y .

$$B(x, y) = \frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)}, \quad \text{for } x > 0, y > 0 \quad (28.24)$$

28.7.6.5 Complete elliptic integral of the first kind**[sf.cmath.comp.ellint.1]**

floating-point-type `comp_ellint_1(floating-point-type k);`
 float `comp_ellint_1f(float k);`
 long double `comp_ellint_1l(long double k);`

Effects: These functions compute the complete elliptic integral of the first kind of their respective arguments k .

Returns: $K(k)$, where K is given by Formula 28.25 and k is k .

$$K(k) = F(k, \pi/2), \quad \text{for } |k| \leq 1 \quad (28.25)$$

See also 28.7.6.12.

28.7.6.6 Complete elliptic integral of the second kind**[sf.cmath.comp.ellint.2]**

floating-point-type `comp_ellint_2(floating-point-type k);`
 float `comp_ellint_2f(float k);`
 long double `comp_ellint_2l(long double k);`

Effects: These functions compute the complete elliptic integral of the second kind of their respective arguments k .

Returns: $E(k)$, where E is given by Formula 28.26 and k is k .

$$E(k) = E(k, \pi/2), \quad \text{for } |k| \leq 1 \quad (28.26)$$

See also 28.7.6.13.

28.7.6.7 Complete elliptic integral of the third kind**[sf.cmath.comp.ellint.3]**

floating-point-type `comp_ellint_3(floating-point-type k, floating-point-type nu);`
 float `comp_ellint_3f(float k, float nu);`
 long double `comp_ellint_3l(long double k, long double nu);`

Effects: These functions compute the complete elliptic integral of the third kind of their respective arguments k and ν .

Returns: $\Pi(\nu, k)$, where Π is given by Formula 28.27, k is k , and ν is ν .

$$\Pi(\nu, k) = \Pi(\nu, k, \pi/2), \quad \text{for } |k| \leq 1 \quad (28.27)$$

See also 28.7.6.14.

28.7.6.8 Regular modified cylindrical Bessel functions**[sf.cmath.cyl.bessel.i]**

```
floating-point-type cyl_bessel_i(floating-point-type nu, floating-point-type x);
float cyl_bessel_if(float nu, float x);
long double cyl_bessel_il(long double nu, long double x);
```

Effects: These functions compute the regular modified cylindrical Bessel functions of their respective arguments *nu* and *x*.

Returns: $I_\nu(x)$, where I_ν is given by Formula 28.28, ν is *nu*, and *x* is *x*.

$$I_\nu(x) = i^{-\nu} J_\nu(ix) = \sum_{k=0}^{\infty} \frac{(x/2)^{\nu+2k}}{k! \Gamma(\nu+k+1)}, \quad \text{for } x \geq 0 \quad (28.28)$$

Remarks: The effect of calling each of these functions is implementation-defined if *nu* $\geq$ 128.

See also 28.7.6.9.

28.7.6.9 Cylindrical Bessel functions of the first kind**[sf.cmath.cyl.bessel.j]**

```
floating-point-type cyl_bessel_j(floating-point-type nu, floating-point-type x);
float cyl_bessel_jf(float nu, float x);
long double cyl_bessel_jl(long double nu, long double x);
```

Effects: These functions compute the cylindrical Bessel functions of the first kind of their respective arguments *nu* and *x*.

Returns: $J_\nu(x)$, where J_ν is given by Formula 28.29, ν is *nu*, and *x* is *x*.

$$J_\nu(x) = \sum_{k=0}^{\infty} \frac{(-1)^k (x/2)^{\nu+2k}}{k! \Gamma(\nu+k+1)}, \quad \text{for } x \geq 0 \quad (28.29)$$

Remarks: The effect of calling each of these functions is implementation-defined if *nu* $\geq$ 128.

28.7.6.10 Irregular modified cylindrical Bessel functions**[sf.cmath.cyl.bessel.k]**

```
floating-point-type cyl_bessel_k(floating-point-type nu, floating-point-type x);
float cyl_bessel_kf(float nu, float x);
long double cyl_bessel_kl(long double nu, long double x);
```

Effects: These functions compute the irregular modified cylindrical Bessel functions of their respective arguments *nu* and *x*.

Returns: $K_\nu(x)$, where K_ν is given by Formula 28.30, ν is *nu*, and *x* is *x*.

$$K_\nu(x) = (\pi/2) i^{\nu+1} (J_\nu(ix) + iN_\nu(ix)) = \begin{cases} \frac{\pi}{2} \frac{I_{-\nu}(x) - I_\nu(x)}{\sin \nu\pi}, & \text{for } x \geq 0 \text{ and non-integral } \nu \\ \frac{\pi}{2} \lim_{\mu \rightarrow \nu} \frac{I_{-\mu}(x) - I_\mu(x)}{\sin \mu\pi}, & \text{for } x \geq 0 \text{ and integral } \nu \end{cases} \quad (28.30)$$

Remarks: The effect of calling each of these functions is implementation-defined if *nu* $\geq$ 128.

See also 28.7.6.8, 28.7.6.9, 28.7.6.11.

28.7.6.11 Cylindrical Neumann functions**[sf.cmath.cyl.neumann]**

```
floating-point-type cyl_neumann(floating-point-type nu, floating-point-type x);
float cyl_neumannf(float nu, float x);
long double cyl_neumannl(long double nu, long double x);
```

Effects: These functions compute the cylindrical Neumann functions, also known as the cylindrical Bessel functions of the second kind, of their respective arguments *nu* and *x*.

Returns: $N_\nu(x)$, where N_ν is given by Formula 28.31, ν is *nu*, and *x* is *x*.

$$N_\nu(x) = \begin{cases} \frac{J_\nu(x) \cos \nu\pi - J_{-\nu}(x)}{\sin \nu\pi}, & \text{for } x \geq 0 \text{ and non-integral } \nu \\ \lim_{\mu \rightarrow \nu} \frac{J_\mu(x) \cos \mu\pi - J_{-\mu}(x)}{\sin \mu\pi}, & \text{for } x \geq 0 \text{ and integral } \nu \end{cases} \quad (28.31)$$

Remarks: The effect of calling each of these functions is implementation-defined if $\text{nu} \geq 128$.

See also 28.7.6.9.

28.7.6.12 Incomplete elliptic integral of the first kind [sf.cmath.ellint.1]

```
floating-point-type ellint_1(floating-point-type k, floating-point-type phi);
float ellint_1f(float k, float phi);
long double ellint_1l(long double k, long double phi);
```

Effects: These functions compute the incomplete elliptic integral of the first kind of their respective arguments k and ϕ (ϕ measured in radians).

Returns: $F(k, \phi)$, where F is given by Formula 28.32, k is k , and ϕ is ϕ .

$$F(k, \phi) = \int_0^\phi \frac{d\theta}{\sqrt{1 - k^2 \sin^2 \theta}}, \quad \text{for } |k| \leq 1 \quad (28.32)$$

28.7.6.13 Incomplete elliptic integral of the second kind [sf.cmath.ellint.2]

```
floating-point-type ellint_2(floating-point-type k, floating-point-type phi);
float ellint_2f(float k, float phi);
long double ellint_2l(long double k, long double phi);
```

Effects: These functions compute the incomplete elliptic integral of the second kind of their respective arguments k and ϕ (ϕ measured in radians).

Returns: $E(k, \phi)$, where E is given by Formula 28.33, k is k , and ϕ is ϕ .

$$E(k, \phi) = \int_0^\phi \sqrt{1 - k^2 \sin^2 \theta} d\theta, \quad \text{for } |k| \leq 1 \quad (28.33)$$

28.7.6.14 Incomplete elliptic integral of the third kind [sf.cmath.ellint.3]

```
floating-point-type ellint_3(floating-point-type k, floating-point-type nu,
                             floating-point-type phi);
float ellint_3f(float k, float nu, float phi);
long double ellint_3l(long double k, long double nu, long double phi);
```

Effects: These functions compute the incomplete elliptic integral of the third kind of their respective arguments k , ν , and ϕ (ϕ measured in radians).

Returns: $\Pi(\nu, k, \phi)$, where Π is given by Formula 28.34, ν is ν , k is k , and ϕ is ϕ .

$$\Pi(\nu, k, \phi) = \int_0^\phi \frac{d\theta}{(1 - \nu \sin^2 \theta) \sqrt{1 - k^2 \sin^2 \theta}}, \quad \text{for } |k| \leq 1 \quad (28.34)$$

28.7.6.15 Exponential integral [sf.cmath.expint]

```
floating-point-type expint(floating-point-type x);
float expintf(float x);
long double expintl(long double x);
```

Effects: These functions compute the exponential integral of their respective arguments x .

Returns: $Ei(x)$, where Ei is given by Formula 28.35 and x is x .

$$Ei(x) = - \int_{-x}^{\infty} \frac{e^{-t}}{t} dt \quad (28.35)$$

28.7.6.16 Hermite polynomials [sf.cmath.hermite]

```
floating-point-type hermite(unsigned n, floating-point-type x);
float hermitef(unsigned n, float x);
long double hermitel(unsigned n, long double x);
```

Effects: These functions compute the Hermite polynomials of their respective arguments n and x .

Returns: $H_n(x)$, where H_n is given by Formula 28.36, n is n , and x is x .

$$H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2} \quad (28.36)$$

Remarks: The effect of calling each of these functions is implementation-defined if $n \geq 128$.

28.7.6.17 Laguerre polynomials**[sf.cmath.laguerre]**

floating-point-type laguerre(unsigned n, *floating-point-type* x);
float laguerref(unsigned n, float x);
long double laguerrel(unsigned n, long double x);

Effects: These functions compute the Laguerre polynomials of their respective arguments n and x.

Returns: $L_n(x)$, where L_n is given by Formula 28.37, n is n, and x is x.

$$L_n(x) = \frac{e^x}{n!} \frac{d^n}{dx^n} (x^n e^{-x}), \quad \text{for } x \geq 0 \quad (28.37)$$

Remarks: The effect of calling each of these functions is implementation-defined if n >= 128.

28.7.6.18 Legendre polynomials**[sf.cmath.legendre]**

floating-point-type legendre(unsigned l, *floating-point-type* x);
float legendref(unsigned l, float x);
long double legendrel(unsigned l, long double x);

Effects: These functions compute the Legendre polynomials of their respective arguments l and x.

Returns: $P_\ell(x)$, where P_ℓ is given by Formula 28.38, l is l, and x is x.

$$P_\ell(x) = \frac{1}{2^\ell \ell!} \frac{d^\ell}{dx^\ell} (x^2 - 1)^\ell, \quad \text{for } |x| \leq 1 \quad (28.38)$$

Remarks: The effect of calling each of these functions is implementation-defined if l >= 128.

28.7.6.19 Riemann zeta function**[sf.cmath.riemann.zeta]**

floating-point-type riemann_zeta(*floating-point-type* x);
float riemann_zetaf(float x);
long double riemann_zetal(long double x);

Effects: These functions compute the Riemann zeta function of their respective arguments x.

Returns: $\zeta(x)$, where ζ is given by Formula 28.39 and x is x.

$$\zeta(x) = \begin{cases} \sum_{k=1}^{\infty} k^{-x}, & \text{for } x > 1 \\ \frac{1}{1-2^{1-x}} \sum_{k=1}^{\infty} (-1)^{k-1} k^{-x}, & \text{for } 0 \leq x \leq 1 \\ 2^x \pi^{x-1} \sin\left(\frac{\pi x}{2}\right) \Gamma(1-x) \zeta(1-x), & \text{for } x < 0 \end{cases} \quad (28.39)$$

28.7.6.20 Spherical Bessel functions of the first kind**[sf.cmath.sph.bessel]**

floating-point-type sph_bessel(unsigned n, *floating-point-type* x);
float sph_besself(unsigned n, float x);
long double sph_bessell(unsigned n, long double x);

Effects: These functions compute the spherical Bessel functions of the first kind of their respective arguments n and x.

Returns: $j_n(x)$, where j_n is given by Formula 28.40, n is n, and x is x.

$$j_n(x) = (\pi/2x)^{1/2} J_{n+1/2}(x), \quad \text{for } x \geq 0 \quad (28.40)$$

Remarks: The effect of calling each of these functions is implementation-defined if n >= 128.

See also 28.7.6.9.

28.7.6.21 Spherical associated Legendre functions

[sf.cmath.sph.legendre]

```
floating-point-type sph_legendre(unsigned l, unsigned m, floating-point-type theta);
float sph_legendref(unsigned l, unsigned m, float theta);
long double sph_legendrel(unsigned l, unsigned m, long double theta);
```

Effects: These functions compute the spherical associated Legendre functions of their respective arguments *l*, *m*, and *theta* (*theta* measured in radians).

Returns: $Y_\ell^m(\theta, 0)$, where Y_ℓ^m is given by Formula 28.41, *l* is *l*, *m* is *m*, and θ is *theta*.

$$Y_\ell^m(\theta, \phi) = (-1)^m \left[\frac{(2\ell+1)(\ell-m)!}{4\pi(\ell+m)!} \right]^{1/2} P_\ell^m(\cos \theta) e^{im\phi}, \quad \text{for } |m| \leq \ell \quad (28.41)$$

Remarks: The effect of calling each of these functions is implementation-defined if *l* $\geq$ 128.

See also 28.7.6.3.

28.7.6.22 Spherical Neumann functions

[sf.cmath.sph.neumann]

```
floating-point-type sph_neumann(unsigned n, floating-point-type x);
float sph_neumannf(unsigned n, float x);
long double sph_neumannl(unsigned n, long double x);
```

Effects: These functions compute the spherical Neumann functions, also known as the spherical Bessel functions of the second kind, of their respective arguments *n* and *x*.

Returns: $n_n(x)$, where n_n is given by Formula 28.42, *n* is *n*, and *x* is *x*.

$$n_n(x) = (\pi/2x)^{1/2} N_{n+1/2}(x), \quad \text{for } x \geq 0 \quad (28.42)$$

Remarks: The effect of calling each of these functions is implementation-defined if *n* $\geq$ 128.

See also 28.7.6.11.

}

```

28.8.2 Mathematical constants

[math.constants]

The library-defined partial specializations of mathematical constant variable templates are initialized with the nearest representable values of e , $\log_2 e$, $\log_{10} e$, π , $\frac{1}{\pi}$, $\frac{1}{\sqrt{\pi}}$, $\ln 2$, $\ln 10$, $\sqrt{2}$, $\sqrt{3}$, $\frac{1}{\sqrt{3}}$, the Euler-Mascheroni γ constant, and the golden ratio ϕ constant $\frac{1+\sqrt{5}}{2}$, respectively.

Pursuant to 16.4.5.2.1, a program may partially or explicitly specialize a mathematical constant variable template provided that the specialization depends on a program-defined type.

A program that instantiates a primary template of a mathematical constant variable template is ill-formed.

29 Time library

[time]

29.1 General

[time.general]

This Clause describes the chrono library (29.2) and various C functions (29.14) that provide generally useful time utilities, as summarized in Table 98.

Table 98 — Time library summary [tab:time.summary]

Subclause	Header
29.3	<i>Cpp17Clock</i> requirements
29.4	Time-related traits <chrono>
29.5	Class template duration
29.6	Class template time_point
29.7	Clocks
29.8	Civil calendar
29.9	Class template hh_mm_ss
29.10	12/24 hour functions
29.11	Time zones
29.12	Formatting
29.13	Parsing
29.14	C library time utilities <ctime>

Let *STATICALLY-WIDEN*<charT>("...") be "..." if charT is char and L"..." if charT is wchar_t.

29.2 Header <chrono> synopsis

[time.syn]

```
#include <compare> // see 17.11.1

namespace std::chrono {

29.3 Cpp17Clock requirements

[time.clock.req]

A clock is a bundle consisting of a `duration`, a `time_point`, and a function `now()` to get the current `time_point`. The origin of the clock's `time_point` is referred to as the clock's *epoch*. A clock shall meet the requirements in Table 99.

In Table 99 C1 and C2 denote clock types. `t1` and `t2` are values returned by `C1::now()` where the call returning `t1` happens before (6.9.2) the call returning `t2` and both of these calls occur before `C1::time_point::max()`.

NOTE 1 This means C1 did not wrap around between `t1` and `t2`.

Table 99 — Cpp17Clock requirements [tab:time.clock]

Expression	Return type	Operational semantics
<code>C1::rep</code>	An arithmetic type or a class emulating an arithmetic type	The representation type of <code>C1::duration</code> .
<code>C1::period</code>	a specialization of <code>ratio</code>	The tick period of the clock in seconds.
<code>C1::duration</code>	<code>chrono::duration<C1::rep, C1::period></code>	The <code>duration</code> type of the clock.
<code>C1::time_point</code>	<code>chrono::time_point<C1></code> or <code>chrono::time_point<C2, C1::duration></code>	The <code>time_point</code> type of the clock. C1 and C2 shall refer to the same epoch.
<code>C1::is_steady</code>	<code>const bool</code>	<code>true</code> if <code>t1 <= t2</code> is always <code>true</code> and the time between clock ticks is constant, otherwise <code>false</code> .
<code>C1::now()</code>	<code>C1::time_point</code>	Returns a <code>time_point</code> object representing the current point in time.

NOTE 2 The relative difference in durations between those reported by a given clock and the SI definition is a measure of the quality of implementation.

A type TC meets the Cpp17TrivialClock requirements if

- TC meets the Cpp17Clock requirements,
- the types `TC::rep`, `TC::duration`, and `TC::time_point` meet the Cpp17EqualityComparable (Table 28) and Cpp17LessThanComparable (Table 29) and Cpp17Swappable (16.4.4.3) requirements and the requirements of numeric types (28.2),

NOTE 3 This means, in particular, that operations on these types will not throw exceptions.

- the function `TC::now()` does not throw exceptions, and
- the type `TC::time_point::clock` meets the Cpp17TrivialClock requirements, recursively.

29.4 Time-related traits

[time.traits]

29.4.1 treat_as_floating_point

[time.traits.is.fp]

```
template<class Rep> struct treat_as_floating_point : is_floating_point<Rep> { };
```

The `duration` template uses the `treat_as_floating_point` trait to help determine if a `duration` object can be converted to another `duration` with a different tick period. If `treat_as_floating_point_v<Rep>` is `true`, then implicit conversions are allowed among durations. Otherwise, the implicit convertibility depends on the tick periods of the durations.

NOTE The intention of this trait is to indicate whether a given class behaves like a floating-point type, and thus allows division of one value by another with acceptable loss of precision. If `treat_as_floating_point_v<Rep>` is `false`, `Rep` will be treated as if it behaved like an integral type for the purpose of these conversions.

29.4.2 duration_values

[time.traits.duration_values]

```
template<class Rep>
struct duration_values {
public:
    static constexpr Rep zero() noexcept;
    static constexpr Rep min() noexcept;
    static constexpr Rep max() noexcept;
};
```

The `duration` template uses the `duration_values` trait to construct special values of the duration's representation (`Rep`). This is done because the representation can be a class type with behavior that requires some other implementation to return these special values. In that case, the author of that class type should specialize `duration_values` to return the indicated values.

```
static constexpr Rep zero() noexcept;
```

Returns: `Rep(0)`.

NOTE `Rep(0)` is specified instead of `Rep()` because `Rep()` can have some other meaning, such as an uninitialized value.

Remarks: The value returned shall be the additive identity.

```
static constexpr Rep min() noexcept;
```

Returns: `numeric_limits<Rep>::lowest()`.

Remarks: The value returned shall compare less than or equal to `zero()`.

```
static constexpr Rep max() noexcept;
```

Returns: `numeric_limits<Rep>::max()`.

Remarks: The value returned shall compare greater than `zero()`.

29.4.3 Specializations of common_type

[time.traits.specializations]

```
template<class Rep1, class Period1, class Rep2, class Period2>
struct common_type<chrono::duration<Rep1, Period1>, chrono::duration<Rep2, Period2>> {
    using type = chrono::duration<common_type_t<Rep1, Rep2>, see below>;
};
```

The period of the duration indicated by this specialization of `common_type` is the greatest common divisor of `Period1` and `Period2`.

NOTE 1 This can be computed by forming a ratio of the greatest common divisor of `Period1::num` and `Period2::num` and the least common multiple of `Period1::den` and `Period2::den`.

NOTE 2 The typedef name `type` is a synonym for the `duration` with the largest tick period possible where both `duration` arguments will convert to it without requiring a division operation. The representation of this type is intended to be able to hold any value resulting from this conversion with no truncation error, although floating-point durations can have round-off errors.

```
template<class Clock, class Duration1, class Duration2>
struct common_type<chrono::time_point<Clock, Duration1>, chrono::time_point<Clock, Duration2>> {
    using type = chrono::time_point<Clock, common_type_t<Duration1, Duration2>>;
};
```

```
};
```

The common type of two `time_point` types is a `time_point` with the same clock as the two types and the common type of their two durations.

29.4.4 Class template `is_clock`

[time.traits.is.clock]

```
template<class T> struct is_clock;
```

`is_clock` is a *Cpp17UnaryTypeTrait* (21.3.2) with a base characteristic of `true_type` if `T` meets the *Cpp17Clock* requirements (29.3), otherwise `false_type`. For the purposes of the specification of this trait, the extent to which an implementation determines that a type cannot meet the *Cpp17Clock* requirements is unspecified, except that as a minimum a type `T` shall not qualify as a *Cpp17Clock* unless it meets all of the following conditions:

- the *qualified-ids* `T::rep`, `T::period`, `T::duration`, and `T::time_point` are valid and each denotes a type (13.10.3),
- the expression `T::is_steady` is well-formed when treated as an unevaluated operand (7.2.3),
- the expression `T::now()` is well-formed when treated as an unevaluated operand,

The behavior of a program that adds specializations for `is_clock` is undefined.

29.5 Class template `duration`

[time.duration]

29.5.1 General

[time.duration.general]

A `duration` type measures time between two points in time (`time_points`). A `duration` has a representation which holds a count of ticks and a tick period. The tick period is the amount of time which occurs from one tick to the next, in units of seconds. It is expressed as a rational constant using the template `ratio`.

```
namespace std::chrono {
    template<class Rep, class Period = ratio<1>>
    class duration {
    public:
        using rep      = Rep;
        using period    = typename Period::type;

    private:
        rep rep_;      // exposition only

    public:
        // 29.5.2, construct/copy/destroy
        constexpr duration() = default;
        template<class Rep2>
            constexpr explicit duration(const Rep2& r);
        template<class Rep2, class Period2>
            constexpr duration(const duration<Rep2, Period2>& d);
        ~duration() = default;
        duration(const duration&) = default;
        duration& operator=(const duration&) = default;

        // 29.5.3, observer
        constexpr rep count() const;

        // 29.5.4, arithmetic
        constexpr common_type_t<duration> operator+() const;
        constexpr common_type_t<duration> operator-() const;
        constexpr duration& operator++();
        constexpr duration operator++(int);
        constexpr duration& operator--();
        constexpr duration operator--(int);

        constexpr duration& operator+=(const duration& d);
        constexpr duration& operator-=(const duration& d);
    };
}
```

```

constexpr duration& operator*=(const rep& rhs);
constexpr duration& operator/=(const rep& rhs);
constexpr duration& operator%=(const rep& rhs);
constexpr duration& operator%=(const duration& rhs);

// 29.5.5, special values
static constexpr duration zero() noexcept;
static constexpr duration min() noexcept;
static constexpr duration max() noexcept;
};
}

```

Rep shall be an arithmetic type or a class emulating an arithmetic type. If `duration` is instantiated with a `duration` type as the argument for the template parameter `Rep`, the program is ill-formed.

If `Period` is not a specialization of `ratio`, the program is ill-formed. If `Period::num` is not positive, the program is ill-formed.

Members of `duration` do not throw exceptions other than those thrown by the indicated operations on their representations.

The defaulted copy constructor of `duration` shall be a `constexpr` function if and only if the required initialization of the member `rep_` for copy and move, respectively, would be `constexpr-suitable` (9.2.6).

EXAMPLE

```

duration<long, ratio<60>> d0;           // holds a count of minutes using a long
duration<long long, milli> d1;         // holds a count of milliseconds using a long long
duration<double, ratio<1, 30>> d2;     // holds a count with a tick period of  $\frac{1}{30}$  of a second
                                         // (30 Hz) using a double

```

29.5.2 Constructors

[time.duration.cons]

```
template<class Rep2>
```

```
constexpr explicit duration(const Rep2& r);
```

Constraints: `is_convertible_v<const Rep2&, rep>` is true and

- `treat_as_floating_point_v<rep>` is true or
- `treat_as_floating_point_v<Rep2>` is false.

EXAMPLE 1

```

duration<int, milli> d(3);             // OK
duration<int, milli> d(3.5);           // error

```

Effects: Initializes `rep_` with `r`.

```
template<class Rep2, class Period2>
```

```
constexpr duration(const duration<Rep2, Period2>& d);
```

Constraints: No overflow is induced in the conversion and `treat_as_floating_point_v<rep>` is true or both `ratio_divide<Period2, period>::den` is 1 and `treat_as_floating_point_v<Rep2>` is false.

NOTE This requirement prevents implicit truncation error when converting between integral-based `duration` types. Such a construction can lead to confusion about the value of the `duration`.

EXAMPLE 2

```

duration<int, milli> ms(3);
duration<int, micro> us = ms;         // OK
duration<int, milli> ms2 = us;        // error

```

Effects: Initializes `rep_` with `duration_cast<duration>(d).count()`.

29.5.3 Observer

[time.duration.observer]

```
constexpr rep count() const;
```

Returns: `rep_`.

29.5.4 Arithmetic**[time.duration.arithmetic]**

```
constexpr common_type_t<duration> operator+() const;
```

Returns: common_type_t<duration>(*this).

```
constexpr common_type_t<duration> operator-() const;
```

Returns: common_type_t<duration>(-rep_).

```
constexpr duration& operator++();
```

Effects: Equivalent to: ++rep_.

Returns: *this.

```
constexpr duration operator++(int);
```

Effects: Equivalent to: return duration(rep_++);

```
constexpr duration& operator--();
```

Effects: Equivalent to: --rep_.

Returns: *this.

```
constexpr duration operator--(int);
```

Effects: Equivalent to: return duration(rep_--);

```
constexpr duration& operator+=(const duration& d);
```

Effects: Equivalent to: rep_ += d.count().

Returns: *this.

```
constexpr duration& operator-=(const duration& d);
```

Effects: Equivalent to: rep_ -= d.count().

Returns: *this.

```
constexpr duration& operator*=(const rep& rhs);
```

Effects: Equivalent to: rep_ *= rhs.

Returns: *this.

```
constexpr duration& operator/=(const rep& rhs);
```

Effects: Equivalent to: rep_ /= rhs.

Returns: *this.

```
constexpr duration& operator%=(const rep& rhs);
```

Effects: Equivalent to: rep_ %= rhs.

Returns: *this.

```
constexpr duration& operator%=(const duration& rhs);
```

Effects: Equivalent to: rep_ %= rhs.count().

Returns: *this.

29.5.5 Special values**[time.duration.special]**

```
static constexpr duration zero() noexcept;
```

Returns: duration(duration_values<rep>::zero()).

```
static constexpr duration min() noexcept;
```

Returns: duration(duration_values<rep>::min()).

```
static constexpr duration max() noexcept;
```

Returns: duration(duration_values<rep>::max()).

29.5.6 Non-member arithmetic**[time.duration.nonmember]**

In the function descriptions that follow, unless stated otherwise, let CD represent the return type of the function.

```
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
operator+(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
Returns: CD(CD(lhs).count() + CD(rhs).count()).
```

```
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
operator-(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
Returns: CD(CD(lhs).count() - CD(rhs).count()).
```

```
template<class Rep1, class Period, class Rep2>
constexpr duration<common_type_t<Rep1, Rep2>, Period>
operator*(const duration<Rep1, Period>& d, const Rep2& s);
Constraints: is_convertible_v<const Rep2&, common_type_t<Rep1, Rep2>> is true.
Returns: CD(CD(d).count() * s).
```

```
template<class Rep1, class Rep2, class Period>
constexpr duration<common_type_t<Rep1, Rep2>, Period>
operator*(const Rep1& s, const duration<Rep2, Period>& d);
Constraints: is_convertible_v<const Rep1&, common_type_t<Rep1, Rep2>> is true.
Returns: d * s.
```

```
template<class Rep1, class Period, class Rep2>
constexpr duration<common_type_t<Rep1, Rep2>, Period>
operator/(const duration<Rep1, Period>& d, const Rep2& s);
Constraints: is_convertible_v<const Rep2&, common_type_t<Rep1, Rep2>> is true and Rep2 is
not a specialization of duration.
Returns: CD(CD(d).count() / s).
```

```
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr common_type_t<Rep1, Rep2>
operator/(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
Let CD be common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>.
Returns: CD(lhs).count() / CD(rhs).count().
```

```
template<class Rep1, class Period, class Rep2>
constexpr duration<common_type_t<Rep1, Rep2>, Period>
operator%(const duration<Rep1, Period>& d, const Rep2& s);
Constraints: is_convertible_v<const Rep2&, common_type_t<Rep1, Rep2>> is true and Rep2 is
not a specialization of duration.
Returns: CD(CD(d).count() % s).
```

```
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
operator%(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
Returns: CD(CD(lhs).count() % CD(rhs).count()).
```

29.5.7 Comparisons**[time.duration.comparisons]**

In the function descriptions that follow, CT represents common_type_t<A, B>, where A and B are the types of the two arguments to the function.

```
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator==(const duration<Rep1, Period1>& lhs,
                          const duration<Rep2, Period2>& rhs);
```

Returns: CT(lhs).count() == CT(rhs).count().

```
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator<(const duration<Rep1, Period1>& lhs,
                        const duration<Rep2, Period2>& rhs);
```

Returns: CT(lhs).count() < CT(rhs).count().

```
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator>(const duration<Rep1, Period1>& lhs,
                        const duration<Rep2, Period2>& rhs);
```

Returns: rhs < lhs.

```
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator<=(const duration<Rep1, Period1>& lhs,
                         const duration<Rep2, Period2>& rhs);
```

Returns: !(rhs < lhs).

```
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator>=(const duration<Rep1, Period1>& lhs,
                         const duration<Rep2, Period2>& rhs);
```

Returns: !(lhs < rhs).

```
template<class Rep1, class Period1, class Rep2, class Period2>
requires three_way_comparable<typename CT::rep>
constexpr auto operator<=>(const duration<Rep1, Period1>& lhs,
                          const duration<Rep2, Period2>& rhs);
```

Returns: CT(lhs).count() <=> CT(rhs).count().

29.5.8 Conversions

[time.duration.cast]

```
template<class ToDuration, class Rep, class Period>
constexpr ToDuration duration_cast(const duration<Rep, Period>& d);
```

Constraints: ToDuration is a specialization of duration.

Returns: Let CF be ratio_divide<Period, typename ToDuration::period>, and CR be common_type<typename ToDuration::rep, Rep, intmax_t>::type.

— If CF::num == 1 and CF::den == 1, returns

ToDuration(static_cast<typename ToDuration::rep>(d.count()))

— otherwise, if CF::num != 1 and CF::den == 1, returns

ToDuration(static_cast<typename ToDuration::rep>(
 static_cast<CR>(d.count()) * static_cast<CR>(CF::num)))

— otherwise, if CF::num == 1 and CF::den != 1, returns

ToDuration(static_cast<typename ToDuration::rep>(
 static_cast<CR>(d.count()) / static_cast<CR>(CF::den)))

— otherwise, returns

ToDuration(static_cast<typename ToDuration::rep>(
 static_cast<CR>(d.count()) * static_cast<CR>(CF::num) / static_cast<CR>(CF::den)))

NOTE This function does not use any implicit conversions; all conversions are done with `static_cast`. It avoids multiplications and divisions when it is known at compile time that one or more arguments is 1. Intermediate computations are carried out in the widest representation and only converted to the destination representation at the final step.

```
template<class ToDuration, class Rep, class Period>
constexpr ToDuration floor(const duration<Rep, Period>& d);
```

Constraints: ToDuration is a specialization of duration.

Returns: The greatest result *t* representable in *ToDuration* for which *t* ≤ *d*.

```
template<class ToDuration, class Rep, class Period>
constexpr ToDuration ceil(const duration<Rep, Period>& d);
```

Constraints: *ToDuration* is a specialization of *duration*.

Returns: The least result *t* representable in *ToDuration* for which *t* ≥ *d*.

```
template<class ToDuration, class Rep, class Period>
constexpr ToDuration round(const duration<Rep, Period>& d);
```

Constraints: *ToDuration* is a specialization of *duration* and *treat_as_floating_point_v*<typename *ToDuration::rep*> is false.

Returns: The value of *ToDuration* that is closest to *d*. If there are two closest values, then return the value *t* for which *t* % 2 == 0.

29.5.9 Suffixes for duration literals

[time.duration.literals]

This subclause describes literal suffixes for constructing duration literals. The suffixes *h*, *min*, *s*, *ms*, *us*, *ns* denote duration values of the corresponding types *hours*, *minutes*, *seconds*, *milliseconds*, *microseconds*, and *nanoseconds* respectively if they are applied to *integer-literals*.

If any of these suffixes are applied to a *floating-point-literal* the result is a *chrono::duration* literal with an unspecified floating-point representation.

If any of these suffixes are applied to an *integer-literal* and the resulting *chrono::duration* value cannot be represented in the result type because of overflow, the program is ill-formed.

EXAMPLE The following code shows some duration literals.

```
using namespace std::chrono_literals;
auto constexpr aday=24h;
auto constexpr lesson=45min;
auto constexpr halfanhour=0.5h;

constexpr chrono::hours operator""h(unsigned long long hours);
constexpr chrono::duration<unspecified, ratio<3600, 1>> operator""h(long double hours);
```

Returns: A duration literal representing *hours* hours.

```
constexpr chrono::minutes operator""min(unsigned long long minutes);
constexpr chrono::duration<unspecified, ratio<60, 1>> operator""min(long double minutes);
```

Returns: A duration literal representing *minutes* minutes.

```
constexpr chrono::seconds operator""s(unsigned long long sec);
constexpr chrono::duration<unspecified> operator""s(long double sec);
```

Returns: A duration literal representing *sec* seconds.

NOTE The same suffix *s* is used for *basic_string* but there is no conflict, since duration suffixes apply to numbers and string literal suffixes apply to character array literals.

```
constexpr chrono::milliseconds operator""ms(unsigned long long msec);
constexpr chrono::duration<unspecified, milli> operator""ms(long double msec);
```

Returns: A duration literal representing *msec* milliseconds.

```
constexpr chrono::microseconds operator""us(unsigned long long usec);
constexpr chrono::duration<unspecified, micro> operator""us(long double usec);
```

Returns: A duration literal representing *usec* microseconds.

```
constexpr chrono::nanoseconds operator""ns(unsigned long long nsec);
constexpr chrono::duration<unspecified, nano> operator""ns(long double nsec);
```

Returns: A duration literal representing *nsec* nanoseconds.

29.5.10 Algorithms

[time.duration.alg]

```
template<class Rep, class Period>
constexpr duration<Rep, Period> abs(duration<Rep, Period> d);
```

Constraints: numeric_limits<Rep>::is_signed is true.

Returns: If $d \geq d.zero()$, return d , otherwise return $-d$.

29.5.11 I/O

[time.duration.io]

```
template<class charT, class traits, class Rep, class Period>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const duration<Rep, Period>& d);
```

Effects: Inserts the duration d onto the stream os as if it were implemented as follows:

```
basic_ostringstream<charT, traits> s;
s.flags(os.flags());
s.imbue(os.getloc());
s.precision(os.precision());
s << d.count() << units-suffix;
return os << s.str();
```

where *units-suffix* depends on the type `Period::type` as follows:

- If `Period::type` is `atto`, *units-suffix* is "as".
- Otherwise, if `Period::type` is `femto`, *units-suffix* is "fs".
- Otherwise, if `Period::type` is `pico`, *units-suffix* is "ps".
- Otherwise, if `Period::type` is `nano`, *units-suffix* is "ns".
- Otherwise, if `Period::type` is `micro`, it is implementation-defined whether *units-suffix* is "µs" ("u00b5" or "us").
- Otherwise, if `Period::type` is `milli`, *units-suffix* is "ms".
- Otherwise, if `Period::type` is `centi`, *units-suffix* is "cs".
- Otherwise, if `Period::type` is `deci`, *units-suffix* is "ds".
- Otherwise, if `Period::type` is `ratio<1>`, *units-suffix* is "s".
- Otherwise, if `Period::type` is `deca`, *units-suffix* is "das".
- Otherwise, if `Period::type` is `hecto`, *units-suffix* is "hs".
- Otherwise, if `Period::type` is `kilo`, *units-suffix* is "ks".
- Otherwise, if `Period::type` is `mega`, *units-suffix* is "Ms".
- Otherwise, if `Period::type` is `giga`, *units-suffix* is "Gs".
- Otherwise, if `Period::type` is `tera`, *units-suffix* is "Ts".
- Otherwise, if `Period::type` is `peta`, *units-suffix* is "Ps".
- Otherwise, if `Period::type` is `exa`, *units-suffix* is "Es".
- Otherwise, if `Period::type` is `ratio<60>`, *units-suffix* is "min".
- Otherwise, if `Period::type` is `ratio<3600>`, *units-suffix* is "h".
- Otherwise, if `Period::type` is `ratio<86400>`, *units-suffix* is "d".
- Otherwise, if `Period::type::den == 1`, *units-suffix* is "[num]s".
- Otherwise, *units-suffix* is "[num/den]s".

In the list above, the use of *num* and *den* refers to the static data members of `Period::type`, which are converted to arrays of `charT` using a decimal conversion with no leading zeroes.

Returns: os .

```
template<class charT, class traits, class Rep, class Period, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
            duration<Rep, Period>& d,
```

```
basic_string<charT, traits, Alloc>* abbrev = nullptr,
minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream *is* into the duration *d* using the format flags given in the NTCTS *fmt* as specified in 29.13. If the parse fails to decode a valid duration, *is.setstate(ios_base::failbit)* is called and *d* is not modified. If *%Z* is used and successfully parsed, that value will be assigned to **abbrev* if *abbrev* is non-null. If *%z* (or a modified variant) is used and successfully parsed, that value will be assigned to **offset* if *offset* is non-null.

Returns: *is*.

29.6 Class template `time_point`

[time.point]

29.6.1 General

[time.point.general]

```
namespace std::chrono {
    template<class Clock, class Duration = typename Clock::duration>
    class time_point {
    public:
        using clock      = Clock;
        using duration    = Duration;
        using rep         = typename duration::rep;
        using period      = typename duration::period;

    private:
        duration d_; // exposition only

    public:
        // 29.6.2, construct
        constexpr time_point(); // has value epoch
        constexpr explicit time_point(const duration& d); // same as time_point() + d
        template<class Duration2>
            constexpr time_point(const time_point<clock, Duration2>& t);

        // 29.6.3, observer
        constexpr duration time_since_epoch() const;

        // 29.6.4, arithmetic
        constexpr time_point& operator++();
        constexpr time_point operator++(int);
        constexpr time_point& operator--();
        constexpr time_point operator--(int);
        constexpr time_point& operator+=(const duration& d);
        constexpr time_point& operator-=(const duration& d);

        // 29.6.5, special values
        static constexpr time_point min() noexcept;
        static constexpr time_point max() noexcept;
    };
}
```

If `Duration` is not a specialization of `duration`, the program is ill-formed.

29.6.2 Constructors

[time.point.cons]

```
constexpr time_point();
```

Effects: Initializes *d_* with `duration::zero()`. Such a `time_point` object represents the epoch.

```
constexpr explicit time_point(const duration& d);
```

Effects: Initializes *d_* with *d*. Such a `time_point` object represents the epoch + *d*.

```
template<class Duration2>
```

```
constexpr time_point(const time_point<clock, Duration2>& t);
```

Constraints: `is_convertible_v<Duration2, duration>` is true.

Effects: Initializes *d_* with *t.time_since_epoch()*.

29.6.3 Observer**[time.point.observer]**

```
constexpr duration time_since_epoch() const;
```

Returns: d_.

29.6.4 Arithmetic**[time.point.arithmetic]**

```
constexpr time_point& operator++();
```

Effects: Equivalent to: ++d_.

Returns: *this.

```
constexpr time_point operator++(int);
```

Effects: Equivalent to: return time_point{d_++};

```
constexpr time_point& operator--();
```

Effects: Equivalent to: --d_.

Returns: *this.

```
constexpr time_point operator--(int);
```

Effects: Equivalent to: return time_point{d_--};

```
constexpr time_point& operator+=(const duration& d);
```

Effects: Equivalent to: d_ += d.

Returns: *this.

```
constexpr time_point& operator-=(const duration& d);
```

Effects: Equivalent to: d_ -= d.

Returns: *this.

29.6.5 Special values**[time.point.special]**

```
static constexpr time_point min() noexcept;
```

Returns: time_point(duration::min()).

```
static constexpr time_point max() noexcept;
```

Returns: time_point(duration::max()).

29.6.6 Non-member arithmetic**[time.point.nonmember]**

```
template<class Clock, class Duration1, class Rep2, class Period2>
```

```
constexpr time_point<Clock, common_type_t<Duration1, duration<Rep2, Period2>>>
```

```
operator+(const time_point<Clock, Duration1>& lhs, const duration<Rep2, Period2>& rhs);
```

Returns: CT(lhs.time_since_epoch() + rhs), where CT is the type of the return value.

```
template<class Rep1, class Period1, class Clock, class Duration2>
```

```
constexpr time_point<Clock, common_type_t<duration<Rep1, Period1>, Duration2>>
```

```
operator+(const duration<Rep1, Period1>& lhs, const time_point<Clock, Duration2>& rhs);
```

Returns: rhs + lhs.

```
template<class Clock, class Duration1, class Rep2, class Period2>
```

```
constexpr time_point<Clock, common_type_t<Duration1, duration<Rep2, Period2>>>
```

```
operator-(const time_point<Clock, Duration1>& lhs, const duration<Rep2, Period2>& rhs);
```

Returns: CT(lhs.time_since_epoch() - rhs), where CT is the type of the return value.

```
template<class Clock, class Duration1, class Duration2>
```

```
constexpr common_type_t<Duration1, Duration2>
```

```
operator-(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
```

Returns: lhs.time_since_epoch() - rhs.time_since_epoch().

29.6.7 Comparisons

[time.point.comparisons]

```
template<class Clock, class Duration1, class Duration2>
constexpr bool operator==(const time_point<Clock, Duration1>& lhs,
                          const time_point<Clock, Duration2>& rhs);
```

Returns: lhs.time_since_epoch() == rhs.time_since_epoch().

```
template<class Clock, class Duration1, class Duration2>
constexpr bool operator<(const time_point<Clock, Duration1>& lhs,
                        const time_point<Clock, Duration2>& rhs);
```

Returns: lhs.time_since_epoch() < rhs.time_since_epoch().

```
template<class Clock, class Duration1, class Duration2>
constexpr bool operator>(const time_point<Clock, Duration1>& lhs,
                        const time_point<Clock, Duration2>& rhs);
```

Returns: rhs < lhs.

```
template<class Clock, class Duration1, class Duration2>
constexpr bool operator<=(const time_point<Clock, Duration1>& lhs,
                         const time_point<Clock, Duration2>& rhs);
```

Returns: !(rhs < lhs).

```
template<class Clock, class Duration1, class Duration2>
constexpr bool operator>=(const time_point<Clock, Duration1>& lhs,
                         const time_point<Clock, Duration2>& rhs);
```

Returns: !(lhs < rhs).

```
template<class Clock, class Duration1,
        three_way_comparable_with<Duration1> Duration2>
constexpr auto operator<=>(const time_point<Clock, Duration1>& lhs,
                          const time_point<Clock, Duration2>& rhs);
```

Returns: lhs.time_since_epoch() <=> rhs.time_since_epoch().

29.6.8 Conversions

[time.point.cast]

```
template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> time_point_cast(const time_point<Clock, Duration>& t);
```

Constraints: ToDuration is a specialization of duration.

Returns:

time_point<Clock, ToDuration>(duration_cast<ToDuration>(t.time_since_epoch()))

```
template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> floor(const time_point<Clock, Duration>& tp);
```

Constraints: ToDuration is a specialization of duration.

Returns: time_point<Clock, ToDuration>(floor<ToDuration>(tp.time_since_epoch())).

```
template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> ceil(const time_point<Clock, Duration>& tp);
```

Constraints: ToDuration is a specialization of duration.

Returns: time_point<Clock, ToDuration>(ceil<ToDuration>(tp.time_since_epoch())).

```
template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> round(const time_point<Clock, Duration>& tp);
```

Constraints: ToDuration is a specialization of duration, and treat_as_floating_point_v<typename ToDuration::rep> is false.

Returns: time_point<Clock, ToDuration>(round<ToDuration>(tp.time_since_epoch())).

29.7 Clocks

[time.clock]

29.7.1 General

[time.clock.general]

The types defined in 29.7 meet the *Cpp17TrivialClock* requirements (29.3) unless otherwise specified.

29.7.2 Class `system_clock`

[time.clock.system]

29.7.2.1 Overview

[time.clock.system.overview]

```
namespace std::chrono {
    class system_clock {
    public:
        using rep          = see below;
        using period        = ratio<unspecified, unspecified>;
        using duration      = chrono::duration<rep, period>;
        using time_point    = chrono::time_point<system_clock>;
        static constexpr bool is_steady = unspecified;

        static time_point now() noexcept;

        // mapping to/from C type time_t
        static time_t      to_time_t (const time_point& t) noexcept;
        static time_point  from_time_t(time_t t) noexcept;
    };
}
```

Objects of type `system_clock` represent wall clock time from the system-wide realtime clock. Objects of type `sys_time<Duration>` measure time since 1970-01-01 00:00:00 UTC excluding leap seconds. This measure is commonly referred to as *Unix time*. This measure facilitates an efficient mapping between `sys_time` and calendar types (29.8).

EXAMPLE

`sys_seconds{sys_days{1970y/January/1}}.time_since_epoch()` is 0s.
`sys_seconds{sys_days{2000y/January/1}}.time_since_epoch()` is 946'684'800s, which is 10'957 * 86'400s.

29.7.2.2 Members

[time.clock.system.members]

`using system_clock::rep = unspecified;`

Constraints: `system_clock::duration::min() < system_clock::duration::zero()` is true.

NOTE This implies that `rep` is a signed type.

`static time_t to_time_t(const time_point& t) noexcept;`

Returns: A `time_t` object that represents the same point in time as `t` when both values are restricted to the coarser of the precisions of `time_t` and `time_point`. It is implementation-defined whether values are rounded or truncated to the required precision.

`static time_point from_time_t(time_t t) noexcept;`

Returns: A `time_point` object that represents the same point in time as `t` when both values are restricted to the coarser of the precisions of `time_t` and `time_point`. It is implementation-defined whether values are rounded or truncated to the required precision.

29.7.2.3 Non-member functions

[time.clock.system.nonmembers]

`template<class charT, class traits, class Duration>`

`basic_ostream<charT, traits>&`

`operator<<(basic_ostream<charT, traits>& os, const sys_time<Duration>& tp);`

Constraints: `treat_as_floating_point_v<typename Duration::rep>` is false, and `Duration{1} < days{1}` is true.

Effects: Equivalent to:

```
return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{:L%F %T}"), tp);
```

EXAMPLE

```
cout << sys_seconds{0s} << '\n';           // 1970-01-01 00:00:00
cout << sys_seconds{946'684'800s} << '\n';    // 2000-01-01 00:00:00
cout << sys_seconds{946'688'523s} << '\n';    // 2000-01-01 01:02:03
```

```
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const sys_days& dp);
```

Effects: os << year_month_day{dp}.

Returns: os.

```
template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
            sys_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
            minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream is into the `sys_time` tp using the format flags given in the NTCTS fmt as specified in 29.13. If the parse fails to decode a valid date, `is.setstate(ios_base::failbit)` is called and tp is not modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to tp.

Returns: is.

29.7.3 Class utc_clock

[time.clock.utc]

29.7.3.1 Overview

[time.clock.utc.overview]

```
namespace std::chrono {
class utc_clock {
public:
    using rep = a signed arithmetic type;
    using period = ratio<unspecified, unspecified>;
    using duration = chrono::duration<rep, period>;
    using time_point = chrono::time_point<utc_clock>;
    static constexpr bool is_steady = unspecified;

    static time_point now();

    template<class Duration>
    static sys_time<common_type_t<Duration, seconds>>
    to_sys(const utc_time<Duration>& t);
    template<class Duration>
    static utc_time<common_type_t<Duration, seconds>>
    from_sys(const sys_time<Duration>& t);
};
}
```

In contrast to `sys_time`, which does not take leap seconds into account, `utc_clock` and its associated `time_point`, `utc_time`, count time, including leap seconds, since 1970-01-01 00:00:00 UTC.

NOTE 1 The UTC time standard began on 1972-01-01 00:00:10 TAI. To measure time since this epoch instead, one can add/subtract the constant `sys_days{1972y/1/1} - sys_days{1970y/1/1}` (63'072'000s) from the `utc_time`.

EXAMPLE

```
clock_cast<utc_clock>(sys_seconds{sys_days{1970y/January/1}}).time_since_epoch() is 0s.
clock_cast<utc_clock>(sys_seconds{sys_days{2000y/January/1}}).time_since_epoch() is 946'684'822s,
which is 10'957 * 86'400s + 22s.
```

`utc_clock` is not a *Cpp17TrivialClock* unless the implementation can guarantee that `utc_clock::now()` does not propagate an exception.

NOTE 2 `noexcept(from_sys(system_clock::now()))` is false.

29.7.3.2 Member functions

[time.clock.utc.members]

```
static time_point now();
```

Returns: from_sys(system_clock::now()), or a more accurate value of utc_time.

```
template<class Duration>
static sys_time<common_type_t<Duration, seconds>>
to_sys(const utc_time<Duration>& u);
```

Returns: A sys_time t, such that from_sys(t) == u if such a mapping exists. Otherwise u represents a time_point during a positive leap second insertion, the conversion counts that leap second as not inserted, and the last representable value of sys_time prior to the insertion of the leap second is returned.

```
template<class Duration>
static utc_time<common_type_t<Duration, seconds>>
from_sys(const sys_time<Duration>& t);
```

Returns: A utc_time u, such that u.time_since_epoch() - t.time_since_epoch() is equal to the sum of leap seconds that were inserted between t and 1970-01-01. If t is exactly the date of leap second insertion, then the conversion counts that leap second as inserted.

EXAMPLE

```
auto t = sys_days{July/1/2015} - 2ns;
auto u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 25s);
t += 1ns;
u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 25s);
t += 1ns;
u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 26s);
t += 1ns;
u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 26s);
```

29.7.3.3 Non-member functions

[time.clock.utc.nonmembers]

```
template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const utc_time<Duration>& t);
```

Effects: Equivalent to:

```
return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{:L%F %T}"), t);
```

EXAMPLE

```
auto t = sys_days{July/1/2015} - 500ms;
auto u = clock_cast<utc_clock>(t);
for (auto i = 0; i < 8; ++i, u += 250ms)
    cout << u << " UTC\n";
```

Produces this output:

```
2015-06-30 23:59:59.500 UTC
2015-06-30 23:59:59.750 UTC
2015-06-30 23:59:60.000 UTC
2015-06-30 23:59:60.250 UTC
2015-06-30 23:59:60.500 UTC
2015-06-30 23:59:60.750 UTC
2015-07-01 00:00:00.000 UTC
2015-07-01 00:00:00.250 UTC
```

```
template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
            utc_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
```

```
minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream `is` into the `utc_time` `tp` using the format flags given in the NTCTS `fmt` as specified in 29.13. If the parse fails to decode a valid date, `is.setstate(ios_base::failbit)` is called and `tp` is not modified. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to `tp`.

Returns: `is`.

```
struct leap_second_info {
    bool    is_leap_second;
    seconds elapsed;
};
```

The type `leap_second_info` has data members and special members specified above. It has no base classes or members other than those specified.

```
template<class Duration>
leap_second_info get_leap_second_info(const utc_time<Duration>& ut);
```

Returns: A `leap_second_info` `lsi`, where `lsi.is_leap_second` is `true` if `ut` is during a positive leap second insertion, and otherwise `false`. `lsi.elapsed` is the sum of leap seconds between 1970-01-01 and `ut`. If `lsi.is_leap_second` is `true`, the leap second referred to by `ut` is included in the sum.

29.7.4 Class `tai_clock`

[time.clock.tai]

29.7.4.1 Overview

[time.clock.tai.overview]

```
namespace std::chrono {
    class tai_clock {
    public:
        using rep                = a signed arithmetic type;
        using period              = ratio<unspecified, unspecified>;
        using duration            = chrono::duration<rep, period>;
        using time_point          = chrono::time_point<tai_clock>;
        static constexpr bool is_steady = unspecified;

        static time_point now();

        template<class Duration>
            static utc_time<common_type_t<Duration, seconds>>
                to_utc(const tai_time<Duration>&) noexcept;
        template<class Duration>
            static tai_time<common_type_t<Duration, seconds>>
                from_utc(const utc_time<Duration>&) noexcept;
    };
}
```

The clock `tai_clock` measures seconds since 1958-01-01 00:00:00 and is offset 10s ahead of UTC at this date. That is, 1958-01-01 00:00:00 TAI is equivalent to 1957-12-31 23:59:50 UTC. Leap seconds are not inserted into TAI. Therefore every time a leap second is inserted into UTC, UTC shifts another second with respect to TAI. For example by 2000-01-01 there had been 22 positive and 0 negative leap seconds inserted so 2000-01-01 00:00:00 UTC is equivalent to 2000-01-01 00:00:32 TAI (22s plus the initial 10s offset).

`tai_clock` is not a *Cpp17TrivialClock* unless the implementation can guarantee that `tai_clock::now()` does not propagate an exception.

NOTE `noexcept(from_utc(utc_clock::now()))` is `false`.

29.7.4.2 Member functions

[time.clock.tai.members]

```
static time_point now();
```

Returns: `from_utc(utc_clock::now())`, or a more accurate value of `tai_time`.

```
template<class Duration>
static utc_time<common_type_t<Duration, seconds>>
to_utc(const tai_time<Duration>& t) noexcept;
```

Returns:

```
utc_time<common_type_t<Duration, seconds>>{t.time_since_epoch()} - 378691210s
```

NOTE 1

```
378691210s == sys_days{1970y/January/1} - sys_days{1958y/January/1} + 10s
```

```
template<class Duration>
static tai_time<common_type_t<Duration, seconds>>
from_utc(const utc_time<Duration>& t) noexcept;
```

Returns:

```
tai_time<common_type_t<Duration, seconds>>{t.time_since_epoch()} + 378691210s
```

NOTE 2

```
378691210s == sys_days{1970y/January/1} - sys_days{1958y/January/1} + 10s
```

29.7.4.3 Non-member functions

[time.clock.tai.nonmembers]

```
template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const tai_time<Duration>& t);
```

Effects: Equivalent to:

```
return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{:L:F %T}"), t);
```

EXAMPLE

```
auto st = sys_days{2000y/January/1};
auto tt = clock_cast<tai_clock>(st);
cout << format("{0:%F %T %Z} == {1:%F %T %Z}\n", st, tt);
```

Produces this output:

```
2000-01-01 00:00:00 UTC == 2000-01-01 00:00:32 TAI
```

```
template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
            tai_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
            minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream *is* into the *tai_time* *tp* using the format flags given in the NTCTS *fmt* as specified in 29.13. If the parse fails to decode a valid date, *is.setstate(ios_base::failbit)* is called and *tp* is not modified. If *%Z* is used and successfully parsed, that value will be assigned to **abbrev* if *abbrev* is non-null. If *%z* (or a modified variant) is used and successfully parsed, that value will be assigned to **offset* if *offset* is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to *tp*.

Returns: *is*.

29.7.5 Class *gps_clock*

[time.clock.gps]

29.7.5.1 Overview

[time.clock.gps.overview]

```
namespace std::chrono {
class gps_clock {
public:
    using rep = a signed arithmetic type;
    using period = ratio<unspecified, unspecified>;
    using duration = chrono::duration<rep, period>;
    using time_point = chrono::time_point<gps_clock>;
    static constexpr bool is_steady = unspecified;

    static time_point now();
```

```

template<class Duration>
    static utc_time<common_type_t<Duration, seconds>>
        to_utc(const gps_time<Duration>&) noexcept;
template<class Duration>
    static gps_time<common_type_t<Duration, seconds>>
        from_utc(const utc_time<Duration>&) noexcept;
};
}

```

The clock `gps_clock` measures seconds since the first Sunday of January, 1980 00:00:00 UTC. Leap seconds are not inserted into GPS. Therefore every time a leap second is inserted into UTC, UTC shifts another second with respect to GPS. Aside from the offset from 1958y/January/1 to 1980y/January/Sunday[1], GPS is behind TAI by 19s due to the 10s offset between 1958 and 1970 and the additional 9 leap seconds inserted between 1970 and 1980.

`gps_clock` is not a *Cpp17TrivialClock* unless the implementation can guarantee that `gps_clock::now()` does not propagate an exception.

NOTE `noexcept(from_utc(utc_clock::now()))` is false.

29.7.5.2 Member functions

[time.clock.gps.members]

```
static time_point now();
```

Returns: `from_utc(utc_clock::now())`, or a more accurate value of `gps_time`.

```

template<class Duration>
    static utc_time<common_type_t<Duration, seconds>>
        to_utc(const gps_time<Duration>& t) noexcept;

```

Returns:

```
utc_time<common_type_t<Duration, seconds>>{t.time_since_epoch()} + 315964809s
```

NOTE 1

```
315964809s == sys_days{1980y/January/Sunday[1]} - sys_days{1970y/January/1} + 9s
```

```

template<class Duration>
    static gps_time<common_type_t<Duration, seconds>>
        from_utc(const utc_time<Duration>& t) noexcept;

```

Returns:

```
gps_time<common_type_t<Duration, seconds>>{t.time_since_epoch()} - 315964809s
```

NOTE 2

```
315964809s == sys_days{1980y/January/Sunday[1]} - sys_days{1970y/January/1} + 9s
```

29.7.5.3 Non-member functions

[time.clock.gps.nonmembers]

```

template<class charT, class traits, class Duration>
    basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const gps_time<Duration>& t);

```

Effects: Equivalent to:

```
return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{:L%F %T}"), t);
```

EXAMPLE

```

auto st = sys_days{2000y/January/1};
auto gt = clock_cast<gps_clock>(st);
cout << format("{0:%F %T %Z} == {1:%F %T %Z}\n", st, gt);

```

Produces this output:

```
2000-01-01 00:00:00 UTC == 2000-01-01 00:00:13 GPS
```

```
template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
    basic_istream<charT, traits>&
        from_stream(basic_istream<charT, traits>& is, const charT* fmt,
                    gps_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
                    minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream `is` into the `gps_time` `tp` using the format flags given in the NTCTS `fmt` as specified in 29.13. If the parse fails to decode a valid date, `is.setstate(ios_base::failbit)` is called and `tp` is not modified. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to `tp`.

Returns: `is`.

29.7.6 Type `file_clock`

[time.clock.file]

29.7.6.1 Overview

[time.clock.file.overview]

```
namespace std::chrono {
    using file_clock = see below;
}
```

`file_clock` is an alias for a type meeting the *Cpp17TrivialClock* requirements (29.3), and using a signed arithmetic type for `file_clock::rep`. `file_clock` is used to create the `time_point` system used for `file_time_type` (31.12). Its epoch is unspecified, and `noexcept(file_clock::now())` is true.

NOTE The type that `file_clock` denotes can be in a different namespace than `std::chrono`, such as `std::filesystem`.

29.7.6.2 Member functions

[time.clock.file.members]

The type denoted by `file_clock` provides precisely one of the following two sets of static member functions:

```
template<class Duration>
    static sys_time<see below>
        to_sys(const file_time<Duration>&);
template<class Duration>
    static file_time<see below>
        from_sys(const sys_time<Duration>&);
```

OR:

```
template<class Duration>
    static utc_time<see below>
        to_utc(const file_time<Duration>&);
template<class Duration>
    static file_time<see below>
        from_utc(const utc_time<Duration>&);
```

These member functions shall provide `time_point` conversions consistent with those specified by `utc_clock`, `tai_clock`, and `gps_clock`. The `Duration` of the resultant `time_point` is computed from the `Duration` of the input `time_point`.

29.7.6.3 Non-member functions

[time.clock.file.nonmembers]

```
template<class charT, class traits, class Duration>
    basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const file_time<Duration>& t);
```

Effects: Equivalent to:

```
return os << format(os.getloc(), STatically-WIDEN<charT>("{:L%F %T}"), t);
```

```
template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
    basic_istream<charT, traits>&
        from_stream(basic_istream<charT, traits>& is, const charT* fmt,
                    file_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
                    minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream `is` into the `file_time` `tp` using the format flags given in the NTCTS `fmt` as specified in 29.13. If the parse fails to decode a valid date, `is.setstate(ios_base::failbit)` is called and `tp` is not modified. If `%Z` is used and successfully parsed, that value will

be assigned to **abbrev* if *abbrev* is non-null. If *%z* (or a modified variant) is used and successfully parsed, that value will be assigned to **offset* if *offset* is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to *tp*.

Returns: *is*.

29.7.7 Class `steady_clock`

[time.clock.steady]

```
namespace std::chrono {
    class steady_clock {
    public:
        using rep          = unspecified;
        using period        = ratio<unspecified, unspecified>;
        using duration      = chrono::duration<rep, period>;
        using time_point    = chrono::time_point<unspecified, duration>;
        static constexpr bool is_steady = true;

        static time_point now() noexcept;
    };
}
```

Objects of class `steady_clock` represent clocks for which values of `time_point` never decrease as physical time advances and for which values of `time_point` advance at a steady rate relative to real time. That is, the clock may not be adjusted.

29.7.8 Class `high_resolution_clock`

[time.clock.hires]

```
namespace std::chrono {
    class high_resolution_clock {
    public:
        using rep          = unspecified;
        using period        = ratio<unspecified, unspecified>;
        using duration      = chrono::duration<rep, period>;
        using time_point    = chrono::time_point<unspecified, duration>;
        static constexpr bool is_steady = unspecified;

        static time_point now() noexcept;
    };
}
```

Objects of class `high_resolution_clock` represent clocks with the shortest tick period. `high_resolution_clock` may be a synonym for `system_clock` or `steady_clock`.

29.7.9 Local time

[time.clock.local]

The family of time points denoted by `local_time<Duration>` are based on the pseudo clock `local_t`. `local_t` has no member `now()` and thus does not meet the clock requirements. Nevertheless `local_time<Duration>` serves the vital role of representing local time with respect to a not-yet-specified time zone. Aside from being able to get the current time, the complete `time_point` algebra is available for `local_time<Duration>` (just as for `sys_time<Duration>`).

```
template<class charT, class traits, class Duration>
    basic_ostream<charT, traits>&
        operator<< (basic_ostream<charT, traits>& os, const local_time<Duration>& lt);
```

Effects:

```
os << sys_time<Duration>{lt.time_since_epoch()};
```

Returns: *os*.

```
template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
    basic_istream<charT, traits>&
        from_stream(basic_istream<charT, traits>& is, const charT* fmt,
                    local_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
                    minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream *is* into the `local_time` *tp* using the format flags given in the NTCTS *fmt* as specified in 29.13. If the parse fails to decode a valid date, *is.setstate(ios_*

`base::failbit`) is called and `tp` is not modified. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null.

Returns: `is`.

29.7.10 time_point conversions [time.clock.cast]

29.7.10.1 Class template `clock_time_conversion` [time.clock.conv]

```
namespace std::chrono {
    template<class DestClock, class SourceClock>
    struct clock_time_conversion {};
}
```

`clock_time_conversion` serves as a trait which can be used to specify how to convert a source `time_point` of type `time_point<SourceClock, Duration>` to a destination `time_point` of type `time_point<DestClock, Duration>` via a specialization: `clock_time_conversion<DestClock, SourceClock>`. A specialization of `clock_time_conversion<DestClock, SourceClock>` shall provide a const-qualified `operator()` that takes a parameter of type `time_point<SourceClock, Duration>` and returns a `time_point<DestClock, OtherDuration>` representing an equivalent point in time. `OtherDuration` is a `chrono::duration` whose specialization is computed from the input `Duration` in a manner which can vary for each `clock_time_conversion` specialization. A program may specialize `clock_time_conversion` if at least one of the template parameters is a user-defined clock type.

Several specializations are provided by the implementation, as described in 29.7.10.2, 29.7.10.3, 29.7.10.4, and 29.7.10.5.

29.7.10.2 Identity conversions [time.clock.cast.id]

```
template<class Clock>
struct clock_time_conversion<Clock, Clock> {
    template<class Duration>
    time_point<Clock, Duration>
    operator()(const time_point<Clock, Duration>& t) const;
};
```

```
template<class Duration>
time_point<Clock, Duration>
operator()(const time_point<Clock, Duration>& t) const;
```

Returns: `t`.

```
template<>
struct clock_time_conversion<system_clock, system_clock> {
    template<class Duration>
    sys_time<Duration>
    operator()(const sys_time<Duration>& t) const;
};
```

```
template<class Duration>
sys_time<Duration>
operator()(const sys_time<Duration>& t) const;
```

Returns: `t`.

```
template<>
struct clock_time_conversion<utc_clock, utc_clock> {
    template<class Duration>
    utc_time<Duration>
    operator()(const utc_time<Duration>& t) const;
};
```

```
template<class Duration>
utc_time<Duration>
operator()(const utc_time<Duration>& t) const;
```

Returns: `t`.

29.7.10.3 Conversions between system_clock and utc_clock

[time.clock.cast.sys.utc]

```
template<>
struct clock_time_conversion<utc_clock, system_clock> {
    template<class Duration>
        utc_time<common_type_t<Duration, seconds>>
            operator()(const sys_time<Duration>& t) const;
};
```

```
template<class Duration>
    utc_time<common_type_t<Duration, seconds>>
        operator()(const sys_time<Duration>& t) const;
```

Returns: utc_clock::from_sys(t).

```
template<>
struct clock_time_conversion<system_clock, utc_clock> {
    template<class Duration>
        sys_time<common_type_t<Duration, seconds>>
            operator()(const utc_time<Duration>& t) const;
};
```

```
template<class Duration>
    sys_time<common_type_t<Duration, seconds>>
        operator()(const utc_time<Duration>& t) const;
```

Returns: utc_clock::to_sys(t).

29.7.10.4 Conversions between system_clock and other clocks

[time.clock.cast.sys]

```
template<class SourceClock>
struct clock_time_conversion<system_clock, SourceClock> {
    template<class Duration>
        auto operator()(const time_point<SourceClock, Duration>& t) const
            -> decltype(SourceClock::to_sys(t));
};
```

```
template<class Duration>
    auto operator()(const time_point<SourceClock, Duration>& t) const
        -> decltype(SourceClock::to_sys(t));
```

Constraints: SourceClock::to_sys(t) is well-formed.

Mandates: SourceClock::to_sys(t) returns a sys_time<Duration2> for some type Duration2 (29.6.1).

Returns: SourceClock::to_sys(t).

```
template<class DestClock>
struct clock_time_conversion<DestClock, system_clock> {
    template<class Duration>
        auto operator()(const sys_time<Duration>& t) const
            -> decltype(DestClock::from_sys(t));
};
```

```
template<class Duration>
    auto operator()(const sys_time<Duration>& t) const
        -> decltype(DestClock::from_sys(t));
```

Constraints: DestClock::from_sys(t) is well-formed.

Mandates: DestClock::from_sys(t) returns a time_point<DestClock, Duration2> for some type Duration2 (29.6.1).

Returns: DestClock::from_sys(t).

29.7.10.5 Conversions between utc_clock and other clocks**[time.clock.cast.utc]**

```

template<class SourceClock>
struct clock_time_conversion<utc_clock, SourceClock> {
    template<class Duration>
        auto operator()(const time_point<SourceClock, Duration>& t) const
            -> decltype(SourceClock::to_utc(t));
};

template<class Duration>
auto operator()(const time_point<SourceClock, Duration>& t) const
    -> decltype(SourceClock::to_utc(t));

Constraints: SourceClock::to_utc(t) is well-formed.

Mandates: SourceClock::to_utc(t) returns a utc_time<Duration2> for some type Duration2
(29.6.1).

Returns: SourceClock::to_utc(t).

template<class DestClock>
struct clock_time_conversion<DestClock, utc_clock> {
    template<class Duration>
        auto operator()(const utc_time<Duration>& t) const
            -> decltype(DestClock::from_utc(t));
};

template<class Duration>
auto operator()(const utc_time<Duration>& t) const
    -> decltype(DestClock::from_utc(t));

Constraints: DestClock::from_utc(t) is well-formed.

Mandates: DestClock::from_utc(t) returns a time_point<DestClock, Duration2> for some type
Duration2 (29.6.1).

Returns: DestClock::from_utc(t).

```

29.7.10.6 Function template clock_cast**[time.clock.cast.fn]**

```

template<class DestClock, class SourceClock, class Duration>
auto clock_cast(const time_point<SourceClock, Duration>& t);

Constraints: At least one of the following clock time conversion expressions is well-formed:
    — clock_time_conversion<DestClock, SourceClock>{}(t)
    — clock_time_conversion<DestClock, system_clock>{}(
        clock_time_conversion<system_clock, SourceClock>{}(t))
    — clock_time_conversion<DestClock, utc_clock>{}(
        clock_time_conversion<utc_clock, SourceClock>{}(t))
    — clock_time_conversion<DestClock, utc_clock>{}(
        clock_time_conversion<utc_clock, system_clock>{}(
            clock_time_conversion<system_clock, SourceClock>{}(t)))
    — clock_time_conversion<DestClock, system_clock>{}(
        clock_time_conversion<system_clock, utc_clock>{}(
            clock_time_conversion<utc_clock, SourceClock>{}(t)))

```

A clock time conversion expression is considered better than another clock time conversion expression if it involves fewer operator() calls on clock_time_conversion specializations.

Mandates: Among the well-formed clock time conversion expressions from the above list, there is a unique best expression.

Returns: The best well-formed clock time conversion expression in the above list.

29.8 The civil calendar**[time.cal]****29.8.1 General****[time.cal.general]**

The types in 29.8 describe the civil (Gregorian) calendar and its relationship to sys_days and local_days.

29.8.2 Class last_spec**[time.cal.last]**

```
namespace std::chrono {
    struct last_spec {
        explicit last_spec() = default;
    };
}
```

The type `last_spec` is used in conjunction with other calendar types to specify the last in a sequence. For example, depending on context, it can represent the last day of a month, or the last day of the week of a month.

29.8.3 Class day**[time.cal.day]****29.8.3.1 Overview****[time.cal.day.overview]**

```
namespace std::chrono {
    class day {
        unsigned char d_;           // exposition only
    public:
        day() = default;
        constexpr explicit day(unsigned d) noexcept;

        constexpr day& operator++()    noexcept;
        constexpr day  operator++(int) noexcept;
        constexpr day& operator--()    noexcept;
        constexpr day  operator--(int) noexcept;

        constexpr day& operator+=(const days& d) noexcept;
        constexpr day& operator-=(const days& d) noexcept;

        constexpr explicit operator unsigned() const noexcept;
        constexpr bool ok() const noexcept;
    };
}
```

`day` represents a day of a month. It normally holds values in the range 1 to 31, but may hold non-negative values outside this range. It can be constructed with any `unsigned` value, which will be subsequently truncated to fit into `day`'s unspecified internal storage. `day` meets the *Cpp17EqualityComparable* (Table 28) and *Cpp17LessThanComparable* (Table 29) requirements, and participates in basic arithmetic with `days` objects, which represent a difference between two `day` objects.

`day` is a trivially copyable and standard-layout class type.

29.8.3.2 Member functions**[time.cal.day.members]**

```
constexpr explicit day(unsigned d) noexcept;
```

Effects: Initializes `d_` with `d`. The value held is unspecified if `d` is not in the range `[0, 255]`.

```
constexpr day& operator++() noexcept;
```

Effects: `++d_`.

Returns: `*this`.

```
constexpr day operator++(int) noexcept;
```

Effects: `++(*this)`.

Returns: A copy of `*this` as it existed on entry to this member function.

```
constexpr day& operator--() noexcept;
```

Effects: Equivalent to: `--d_`.

Returns: `*this`.

```
constexpr day operator--(int) noexcept;
```

Effects: `--(*this)`.

Returns: A copy of `*this` as it existed on entry to this member function.

```
constexpr day& operator+=(const days& d) noexcept;
```

Effects: `*this = *this + d.`

Returns: `*this.`

```
constexpr day& operator-=(const days& d) noexcept;
```

Effects: `*this = *this - d.`

Returns: `*this.`

```
constexpr explicit operator unsigned() const noexcept;
```

Returns: `d_.`

```
constexpr bool ok() const noexcept;
```

Returns: `1 <= d_ && d_ <= 31.`

29.8.3.3 Non-member functions

[time.cal.day.nonmembers]

```
constexpr bool operator==(const day& x, const day& y) noexcept;
```

Returns: `unsigned{x} == unsigned{y}.`

```
constexpr strong_ordering operator<=(const day& x, const day& y) noexcept;
```

Returns: `unsigned{x} <= unsigned{y}.`

```
constexpr day operator+(const day& x, const days& y) noexcept;
```

Returns: `day(unsigned{x} + y.count()).`

```
constexpr day operator+(const days& x, const day& y) noexcept;
```

Returns: `y + x.`

```
constexpr day operator-(const day& x, const days& y) noexcept;
```

Returns: `x + -y.`

```
constexpr days operator-(const day& x, const day& y) noexcept;
```

Returns: `days{int(unsigned{x}) - int(unsigned{y})}.`

```
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const day& d);
```

Effects: Equivalent to:

```
return os << (d.ok() ?
    format(STATICALLY-WIDEN<charT>("{:%d}"), d) :
    format(STATICALLY-WIDEN<charT>("{:%d} is not a valid day"), d));
```

```
template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
    day& d, basic_string<charT, traits, Alloc>* abbrev = nullptr,
    minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream `is` into the day `d` using the format flags given in the NTCTS `fmt` as specified in 29.13. If the parse fails to decode a valid day, `is.setstate(ios_base::failbit)` is called and `d` is not modified. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null.

Returns: `is.`

```
constexpr chrono::day operator""d(unsigned long long d) noexcept;
```

Returns: `day{static_cast<unsigned>(d)}.`

29.8.4 Class month

[time.cal.month]

29.8.4.1 Overview

[time.cal.month.overview]

```

namespace std::chrono {
    class month {
        unsigned char m_;           // exposition only
    public:
        month() = default;
        constexpr explicit month(unsigned m) noexcept;

        constexpr month& operator++()    noexcept;
        constexpr month operator++(int) noexcept;
        constexpr month& operator--()    noexcept;
        constexpr month operator--(int) noexcept;

        constexpr month& operator+=(const months& m) noexcept;
        constexpr month& operator-=(const months& m) noexcept;

        constexpr explicit operator unsigned() const noexcept;
        constexpr bool ok() const noexcept;
    };
}

```

month represents a month of a year. It normally holds values in the range 1 to 12, but may hold non-negative values outside this range. It can be constructed with any **unsigned** value, which will be subsequently truncated to fit into **month**'s unspecified internal storage. **month** meets the *Cpp17EqualityComparable* (Table 28) and *Cpp17LessThanComparable* (Table 29) requirements, and participates in basic arithmetic with **months** objects, which represent a difference between two **month** objects.

month is a trivially copyable and standard-layout class type.

29.8.4.2 Member functions

[time.cal.month.members]

```
constexpr explicit month(unsigned m) noexcept;
```

Effects: Initializes **m_** with **m**. The value held is unspecified if **m** is not in the range [0, 255].

```
constexpr month& operator++() noexcept;
```

Effects: ***this += months{1}**.

Returns: ***this**.

```
constexpr month operator++(int) noexcept;
```

Effects: **++(*this)**.

Returns: A copy of ***this** as it existed on entry to this member function.

```
constexpr month& operator--() noexcept;
```

Effects: ***this -= months{1}**.

Returns: ***this**.

```
constexpr month operator--(int) noexcept;
```

Effects: **--(*this)**.

Returns: A copy of ***this** as it existed on entry to this member function.

```
constexpr month& operator+=(const months& m) noexcept;
```

Effects: ***this = *this + m**.

Returns: ***this**.

```
constexpr month& operator-=(const months& m) noexcept;
```

Effects: ***this = *this - m**.

Returns: ***this**.

```
constexpr explicit operator unsigned() const noexcept;
```

Returns: `m_`.

```
constexpr bool ok() const noexcept;
```

Returns: `1 <= m_ && m_ <= 12`.

29.8.4.3 Non-member functions

[time.cal.month.nonmembers]

```
constexpr bool operator==(const month& x, const month& y) noexcept;
```

Returns: `unsigned{x} == unsigned{y}`.

```
constexpr strong_ordering operator<=>(const month& x, const month& y) noexcept;
```

Returns: `unsigned{x} <=> unsigned{y}`.

```
constexpr month operator+(const month& x, const months& y) noexcept;
```

Returns:

```
month{modulo(static_cast<long long>(unsigned{x}) + (y.count() - 1), 12) + 1};
```

where `modulo(n, 12)` computes the remainder of `n` divided by 12 using Euclidean division.

NOTE Given a divisor of 12, Euclidean division truncates towards negative infinity and always produces a remainder in the range of `[0, 11]`. Assuming no overflow in the signed summation, this operation results in a `month` holding a value in the range `[1, 12]` even if `!x.ok()`.

EXAMPLE 1 February + months{11} == January.

```
constexpr month operator+(const months& x, const month& y) noexcept;
```

Returns: `y + x`.

```
constexpr month operator-(const month& x, const months& y) noexcept;
```

Returns: `x + -y`.

```
constexpr months operator-(const month& x, const month& y) noexcept;
```

Returns: If `x.ok() == true` and `y.ok() == true`, returns a value `m` in the range `[months{0}, months{11}]` satisfying `y + m == x`. Otherwise the value returned is unspecified.

EXAMPLE 2 January - February == months{11}.

```
template<class charT, class traits>.
```

```
basic_ostream<charT, traits>&
```

```
operator<<(basic_ostream<charT, traits>& os, const month& m);
```

Effects: Equivalent to:

```
return os << (m.ok() ?
    format(os.getloc(), STATICALLY-WIDEN<charT>("{:L%b}"), m) :
    format(os.getloc(), STATICALLY-WIDEN<charT>("{} is not a valid month"),
        static_cast<unsigned>(m)));
```

```
template<class charT, class traits, class Alloc = allocator<charT>>
```

```
basic_istream<charT, traits>&
```

```
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
    month& m, basic_string<charT, traits, Alloc>* abbrev = nullptr,
    minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream `is` into the month `m` using the format flags given in the NTCTS `fmt` as specified in 29.13. If the parse fails to decode a valid month, `is.setstate(ios_base::failbit)` is called and `m` is not modified. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null.

Returns: `is`.

29.8.5 Class year

[time.cal.year]

29.8.5.1 Overview

[time.cal.year.overview]

```

namespace std::chrono {
    class year {
        short y_; // exposition only
    public:
        year() = default;
        constexpr explicit year(int y) noexcept;

        constexpr year& operator++() noexcept;
        constexpr year operator++(int) noexcept;
        constexpr year& operator--() noexcept;
        constexpr year operator--(int) noexcept;

        constexpr year& operator+=(const years& y) noexcept;
        constexpr year& operator-=(const years& y) noexcept;

        constexpr year operator+() const noexcept;
        constexpr year operator-() const noexcept;

        constexpr bool is_leap() const noexcept;

        constexpr explicit operator int() const noexcept;
        constexpr bool ok() const noexcept;

        static constexpr year min() noexcept;
        static constexpr year max() noexcept;
    };
}

```

year represents a year in the civil calendar. It can represent values in the range `[min(),max()]`. It can be constructed with any `int` value, which will be subsequently truncated to fit into **year**'s unspecified internal storage. **year** meets the *Cpp17EqualityComparable* (Table 28) and *Cpp17LessThanComparable* (Table 29) requirements, and participates in basic arithmetic with **years** objects, which represent a difference between two **year** objects.

year is a trivially copyable and standard-layout class type.

29.8.5.2 Member functions

[time.cal.year.members]

```
constexpr explicit year(int y) noexcept;
```

Effects: Initializes `y_` with `y`. The value held is unspecified if `y` is not in the range `[-32767, 32767]`.

```
constexpr year& operator++() noexcept;
```

Effects: `++y_`.

Returns: `*this`.

```
constexpr year& operator++(int) noexcept;
```

Effects: `++(*this)`.

Returns: A copy of `*this` as it existed on entry to this member function.

```
constexpr year& operator--() noexcept;
```

Effects: `--y_`.

Returns: `*this`.

```
constexpr year& operator--(int) noexcept;
```

Effects: `--(*this)`.

Returns: A copy of `*this` as it existed on entry to this member function.

```
constexpr year& operator+=(const years& y) noexcept;
```

Effects: `*this = *this + y.`

Returns: `*this.`

```
constexpr year& operator-=(const years& y) noexcept;
```

Effects: `*this = *this - y.`

Returns: `*this.`

```
constexpr year operator+() const noexcept;
```

Returns: `*this.`

```
constexpr year operator-() const noexcept;
```

Returns: `year{-y_}.`

```
constexpr bool is_leap() const noexcept;
```

Returns: `y_ % 4 == 0 && (y_ % 100 != 0 || y_ % 400 == 0).`

```
constexpr explicit operator int() const noexcept;
```

Returns: `y_.`

```
constexpr bool ok() const noexcept;
```

Returns: `min().y_ <= y_ && y_ <= max().y_.`

```
static constexpr year min() noexcept;
```

Returns: `year{-32767}.`

```
static constexpr year max() noexcept;
```

Returns: `year{32767}.`

29.8.5.3 Non-member functions

[time.cal.year.nonmembers]

```
constexpr bool operator==(const year& x, const year& y) noexcept;
```

Returns: `int{x} == int{y}.`

```
constexpr strong_ordering operator<=(const year& x, const year& y) noexcept;
```

Returns: `int{x} <= int{y}.`

```
constexpr year operator+(const year& x, const years& y) noexcept;
```

Returns: `year{int{x} + static_cast<int>(y.count())}.`

```
constexpr year operator+(const years& x, const year& y) noexcept;
```

Returns: `y + x.`

```
constexpr year operator-(const year& x, const years& y) noexcept;
```

Returns: `x + -y.`

```
constexpr years operator-(const year& x, const year& y) noexcept;
```

Returns: `years{int{x} - int{y}}.`

```
template<class charT, class traits>
```

```
basic_ostream<charT, traits>&
```

```
operator<<(basic_ostream<charT, traits>& os, const year& y);
```

Effects: Equivalent to:

```
return os << (y.ok() ?
```

```
format(STATICALLY-WIDEN<charT>("{:%Y}"), y) :
```

```
format(STATICALLY-WIDEN<charT>("{:%Y} is not a valid year"), y));
```

```
template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
            year& y, basic_string<charT, traits, Alloc>* abbrev = nullptr,
            minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream `is` into the `year` `y` using the format flags given in the NTCTS `fmt` as specified in 29.13. If the parse fails to decode a valid year, `is.setstate(ios_base::failbit)` is called and `y` is not modified. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null.

Returns: `is`.

```
constexpr chrono::year operator""y(unsigned long long y) noexcept;
```

Returns: `year{static_cast<int>(y)}`.

29.8.6 Class `weekday`

[time.cal.wd]

29.8.6.1 Overview

[time.cal.wd.overview]

```
namespace std::chrono {
class weekday {
    unsigned char wd_;           // exposition only
public:
    weekday() = default;
    constexpr explicit weekday(unsigned wd) noexcept;
    constexpr weekday(const sys_days& dp) noexcept;
    constexpr explicit weekday(const local_days& dp) noexcept;

    constexpr weekday& operator++() noexcept;
    constexpr weekday operator++(int) noexcept;
    constexpr weekday& operator--() noexcept;
    constexpr weekday operator--(int) noexcept;

    constexpr weekday& operator+=(const days& d) noexcept;
    constexpr weekday& operator-=(const days& d) noexcept;

    constexpr unsigned c_encoding() const noexcept;
    constexpr unsigned iso_encoding() const noexcept;
    constexpr bool ok() const noexcept;

    constexpr weekday_indexed operator[](unsigned index) const noexcept;
    constexpr weekday_last operator[](last_spec) const noexcept;
};
}
```

`weekday` represents a day of the week in the civil calendar. It normally holds values in the range 0 to 6, corresponding to Sunday through Saturday, but it may hold non-negative values outside this range. It can be constructed with any `unsigned` value, which will be subsequently truncated to fit into `weekday`'s unspecified internal storage. `weekday` meets the *Cpp17EqualityComparable* (Table 28) requirements.

NOTE `weekday` is not *Cpp17LessThanComparable* because there is no universal consensus on which day is the first day of the week. `weekday`'s arithmetic operations treat the days of the week as a circular range, with no beginning and no end.

`weekday` is a trivially copyable and standard-layout class type.

29.8.6.2 Member functions

[time.cal.wd.members]

```
constexpr explicit weekday(unsigned wd) noexcept;
```

Effects: Initializes `wd_` with `wd == 7 ? 0 : wd`. The value held is unspecified if `wd` is not in the range `[0, 255]`.

```
constexpr weekday(const sys_days& dp) noexcept;
```

Effects: Computes what day of the week corresponds to the `sys_days` `dp`, and initializes that day of the week in `wd_`.

EXAMPLE If `dp` represents 1970-01-01, the constructed `weekday` represents Thursday by storing 4 in `wd_`.

```
constexpr explicit weekday(const local_days& dp) noexcept;
```

Effects: Computes what day of the week corresponds to the `local_days` `dp`, and initializes that day of the week in `wd_`.

Postconditions: The value is identical to that constructed from `sys_days{dp.time_since_epoch()}`.

```
constexpr weekday& operator++() noexcept;
```

Effects: `*this += days{1}`.

Returns: `*this`.

```
constexpr weekday operator++(int) noexcept;
```

Effects: `++(*this)`.

Returns: A copy of `*this` as it existed on entry to this member function.

```
constexpr weekday& operator--() noexcept;
```

Effects: `*this -= days{1}`.

Returns: `*this`.

```
constexpr weekday operator--(int) noexcept;
```

Effects: `--(*this)`.

Returns: A copy of `*this` as it existed on entry to this member function.

```
constexpr weekday& operator+=(const days& d) noexcept;
```

Effects: `*this = *this + d`.

Returns: `*this`.

```
constexpr weekday& operator-=(const days& d) noexcept;
```

Effects: `*this = *this - d`.

Returns: `*this`.

```
constexpr unsigned c_encoding() const noexcept;
```

Returns: `wd_`.

```
constexpr unsigned iso_encoding() const noexcept;
```

Returns: `wd_ == 0u ? 7u : wd_`.

```
constexpr bool ok() const noexcept;
```

Returns: `wd_ <= 6`.

```
constexpr weekday_indexed operator[](unsigned index) const noexcept;
```

Returns: `{*this, index}`.

```
constexpr weekday_last operator[](last_spec) const noexcept;
```

Returns: `weekday_last{*this}`.

29.8.6.3 Non-member functions

[time.cal.wd.nonmembers]

```
constexpr bool operator==(const weekday& x, const weekday& y) noexcept;
```

Returns: `x.wd_ == y.wd_`.

```
constexpr weekday operator+(const weekday& x, const days& y) noexcept;
```

Returns:

`weekday{modulo(static_cast<long long>(x.wd_) + y.count(), 7)}`

where `modulo(n, 7)` computes the remainder of `n` divided by 7 using Euclidean division.

NOTE Given a divisor of 7, Euclidean division truncates towards negative infinity and always produces a remainder in the range of $[0, 6]$. Assuming no overflow in the signed summation, this operation results in a `weekday` holding a value in the range $[0, 6]$ even if `!x.ok()`.

EXAMPLE 1 `Monday + days{6} == Sunday`.

```
constexpr weekday operator+(const days& x, const weekday& y) noexcept;
```

Returns: `y + x`.

```
constexpr weekday operator-(const weekday& x, const days& y) noexcept;
```

Returns: `x + -y`.

```
constexpr days operator-(const weekday& x, const weekday& y) noexcept;
```

Returns: If `x.ok() == true` and `y.ok() == true`, returns a value `d` in the range $[\text{days}\{0\}, \text{days}\{6\}]$ satisfying `y + d == x`. Otherwise the value returned is unspecified.

EXAMPLE 2 `Sunday - Monday == days{6}`.

```
template<class charT, class traits>
```

```
basic_ostream<charT, traits>&
```

```
operator<<(basic_ostream<charT, traits>& os, const weekday& wd);
```

Effects: Equivalent to:

```
return os << (wd.ok() ?
    format(os.getloc(), STATICALLY-WIDEN<charT>("{:L%a}"), wd):
    format(os.getloc(), STATICALLY-WIDEN<charT>("{} is not a valid weekday"),
        static_cast<unsigned>(wd.wd_)));
```

```
template<class charT, class traits, class Alloc = allocator<charT>>
```

```
basic_istream<charT, traits>&
```

```
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
    weekday& wd, basic_string<charT, traits, Alloc>* abbrev = nullptr,
    minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream `is` into the `weekday wd` using the format flags given in the NTCTS `fmt` as specified in 29.13. If the parse fails to decode a valid weekday, `is.setstate(ios_base::failbit)` is called and `wd` is not modified. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null.

Returns: `is`.

29.8.7 Class `weekday_indexed`

[time.cal.wdidx]

29.8.7.1 Overview

[time.cal.wdidx.overview]

```
namespace std::chrono {
    class weekday_indexed {
        chrono::weekday wd_; // exposition only
        unsigned char index_; // exposition only

    public:
        weekday_indexed() = default;
        constexpr weekday_indexed(const chrono::weekday& wd, unsigned index) noexcept;

        constexpr chrono::weekday weekday() const noexcept;
        constexpr unsigned index() const noexcept;
        constexpr bool ok() const noexcept;
    };
}
```

`weekday_indexed` represents a `weekday` and a small index in the range 1 to 5. This class is used to represent the first, second, third, fourth, or fifth weekday of a month.

NOTE A `weekday_indexed` object can be constructed by indexing a `weekday` with an `unsigned`.

EXAMPLE

```
constexpr auto wdi = Sunday[2]; // wdi is the second Sunday of an as yet unspecified month
```

```
static_assert(wdi.weekday() == Sunday);
static_assert(wdi.index() == 2);
```

`weekday_indexed` is a trivially copyable and standard-layout class type.

29.8.7.2 Member functions

[time.cal.wdidx.members]

```
constexpr weekday_indexed(const chrono::weekday& wd, unsigned index) noexcept;
```

Effects: Initializes `wd_` with `wd` and `index_` with `index`. The values held are unspecified if `!wd.ok()` or `index` is not in the range `[0, 7]`.

```
constexpr chrono::weekday weekday() const noexcept;
```

Returns: `wd_`.

```
constexpr unsigned index() const noexcept;
```

Returns: `index_`.

```
constexpr bool ok() const noexcept;
```

Returns: `wd_.ok() && 1 <= index_ && index_ <= 5`.

29.8.7.3 Non-member functions

[time.cal.wdidx.nonmembers]

```
constexpr bool operator==(const weekday_indexed& x, const weekday_indexed& y) noexcept;
```

Returns: `x.weekday() == y.weekday() && x.index() == y.index()`.

```
template<class charT, class traits>
```

```
basic_ostream<charT, traits>&
```

```
operator<<(basic_ostream<charT, traits>& os, const weekday_indexed& wdi);
```

Effects: Equivalent to:

```
auto i = wdi.index();
return os << (i >= 1 && i <= 5 ?
    format(os.getloc(), STatically-WIDEN<charT>("{:L}[{}]", wdi.weekday(), i) :
    format(os.getloc(), STatically-WIDEN<charT>("{:L}[{} is not a valid index]",
        wdi.weekday(), i));
```

29.8.8 Class `weekday_last`

[time.cal.wdlast]

29.8.8.1 Overview

[time.cal.wdlast.overview]

```
namespace std::chrono {
```

```
class weekday_last {
```

```
    chrono::weekday wd_; // exposition only
```

```
public:
```

```
constexpr explicit weekday_last(const chrono::weekday& wd) noexcept;
```

```
constexpr chrono::weekday weekday() const noexcept;
```

```
constexpr bool ok() const noexcept;
```

```
};
```

```
}
```

`weekday_last` represents the last weekday of a month.

NOTE A `weekday_last` object can be constructed by indexing a `weekday` with `last`.

EXAMPLE

```
constexpr auto wdl = Sunday[last]; // wdl is the last Sunday of an as yet unspecified month
static_assert(wdl.weekday() == Sunday);
```

`weekday_last` is a trivially copyable and standard-layout class type.

29.8.8.2 Member functions

[time.cal.wdlast.members]

```
constexpr explicit weekday_last(const chrono::weekday& wd) noexcept;
```

Effects: Initializes `wd_` with `wd`.

```
constexpr chrono::weekday weekday() const noexcept;
```

Returns: wd_.

```
constexpr bool ok() const noexcept;
```

Returns: wd_.ok().

29.8.8.3 Non-member functions

[time.cal.wdlast.nonmembers]

```
constexpr bool operator==(const weekday_last& x, const weekday_last& y) noexcept;
```

Returns: x.weekday() == y.weekday().

```
template<class charT, class traits>
```

```
basic_ostream<charT, traits>&
```

```
operator<<(basic_ostream<charT, traits>& os, const weekday_last& wdl);
```

Effects: Equivalent to:

```
return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{:L}[last]"), wdl, weekday());
```

29.8.9 Class month_day

[time.cal.md]

29.8.9.1 Overview

[time.cal.md.overview]

```
namespace std::chrono {
```

```
class month_day {
```

```
    chrono::month m_;           // exposition only
```

```
    chrono::day d_;             // exposition only
```

```
public:
```

```
    month_day() = default;
```

```
    constexpr month_day(const chrono::month& m, const chrono::day& d) noexcept;
```

```
    constexpr chrono::month month() const noexcept;
```

```
    constexpr chrono::day day() const noexcept;
```

```
    constexpr bool ok() const noexcept;
```

```
};
```

```
}
```

month_day represents a specific day of a specific month, but with an unspecified year. month_day meets the *Cpp17EqualityComparable* (Table 28) and *Cpp17LessThanComparable* (Table 29) requirements.

month_day is a trivially copyable and standard-layout class type.

29.8.9.2 Member functions

[time.cal.md.members]

```
constexpr month_day(const chrono::month& m, const chrono::day& d) noexcept;
```

Effects: Initializes m_ with m, and d_ with d.

```
constexpr chrono::month month() const noexcept;
```

Returns: m_.

```
constexpr chrono::day day() const noexcept;
```

Returns: d_.

```
constexpr bool ok() const noexcept;
```

Returns: true if m_.ok() is true, 1d <= d_, and d_ is less than or equal to the number of days in month m_; otherwise returns false. When m_ == February, the number of days is considered to be 29.

29.8.9.3 Non-member functions

[time.cal.md.nonmembers]

```
constexpr bool operator==(const month_day& x, const month_day& y) noexcept;
```

Returns: x.month() == y.month() && x.day() == y.day().

```
constexpr strong_ordering operator<=>(const month_day& x, const month_day& y) noexcept;
```

Effects: Equivalent to:

```
if (auto c = x.month() <=> y.month(); c != 0) return c;
return x.day() <=> y.day();
```

```
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const month_day& md);
```

Effects: Equivalent to:

```
return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{:L}/{:}",
md.month(), md.day());
```

```
template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
month_day& md, basic_string<charT, traits, Alloc>* abbrev = nullptr,
minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream *is* into the *month_day* *md* using the format flags given in the NTCTS *fmt* as specified in 29.13. If the parse fails to decode a valid *month_day*, *is.setstate(ios_base::failbit)* is called and *md* is not modified. If *%Z* is used and successfully parsed, that value will be assigned to **abbrev* if *abbrev* is non-null. If *%z* (or a modified variant) is used and successfully parsed, that value will be assigned to **offset* if *offset* is non-null.

Returns: *is*.

29.8.10 Class *month_day_last*

[time.cal.mdlast]

```
namespace std::chrono {
class month_day_last {
    chrono::month m_; // exposition only

public:
    constexpr explicit month_day_last(const chrono::month& m) noexcept;

    constexpr chrono::month month() const noexcept;
    constexpr bool ok() const noexcept;
};
}
```

month_day_last represents the last day of a month.

NOTE A *month_day_last* object can be constructed using the expression *m/last* or *last/m*, where *m* is an expression of type *month*.

EXAMPLE

```
constexpr auto mdl = February/last; // mdl is the last day of February of an as yet unspecified year
static_assert(mdl.month() == February);
```

month_day_last is a trivially copyable and standard-layout class type.

```
constexpr explicit month_day_last(const chrono::month& m) noexcept;
```

Effects: Initializes *m_* with *m*.

```
constexpr month month() const noexcept;
```

Returns: *m_*.

```
constexpr bool ok() const noexcept;
```

Returns: *m_.ok()*.

```
constexpr bool operator==(const month_day_last& x, const month_day_last& y) noexcept;
```

Returns: *x.month() == y.month()*.

```
constexpr strong_ordering operator<=>(const month_day_last& x, const month_day_last& y) noexcept;
    Returns: x.month() <=> y.month().
```

```
template<class charT, class traits>
    basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const month_day_last& mdl);
    Effects: Equivalent to:
        return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{:L}/last"), mdl.month());
```

29.8.11 Class month_weekday

[time.cal.mwd]

29.8.11.1 Overview

[time.cal.mwd.overview]

```
namespace std::chrono {
    class month_weekday {
        chrono::month m_; // exposition only
        chrono::weekday_indexed wdi_; // exposition only
    public:
        constexpr month_weekday(const chrono::month& m, const chrono::weekday_indexed& wdi) noexcept;

        constexpr chrono::month month() const noexcept;
        constexpr chrono::weekday_indexed weekday_indexed() const noexcept;
        constexpr bool ok() const noexcept;
    };
}
```

month_weekday represents the n^{th} weekday of a month, of an as yet unspecified year. To do this the month_weekday stores a month and a weekday_indexed.

EXAMPLE

```
constexpr auto mwd
    = February/Tuesday[3]; // mwd is the third Tuesday of February of an as yet unspecified year
static_assert(mwd.month() == February);
static_assert(mwd.weekday_indexed() == Tuesday[3]);
```

month_weekday is a trivially copyable and standard-layout class type.

29.8.11.2 Member functions

[time.cal.mwd.members]

```
constexpr month_weekday(const chrono::month& m, const chrono::weekday_indexed& wdi) noexcept;
```

Effects: Initializes m_ with m, and wdi_ with wdi.

```
constexpr chrono::month month() const noexcept;
```

Returns: m_.

```
constexpr chrono::weekday_indexed weekday_indexed() const noexcept;
```

Returns: wdi_.

```
constexpr bool ok() const noexcept;
```

Returns: m_.ok() && wdi_.ok().

29.8.11.3 Non-member functions

[time.cal.mwd.nonmembers]

```
constexpr bool operator==(const month_weekday& x, const month_weekday& y) noexcept;
```

Returns: x.month() == y.month() && x.weekday_indexed() == y.weekday_indexed().

```
template<class charT, class traits>
    basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const month_weekday& mwd);
    Effects: Equivalent to:
        return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{:L}/{:L}"),
            mwd.month(), mwd.weekday_indexed());
```

29.8.12 Class month_weekday_last**[time.cal.mwdlast]****29.8.12.1 Overview****[time.cal.mwdlast.overview]**

```

namespace std::chrono {
    class month_weekday_last {
        chrono::month      m_;      // exposition only
        chrono::weekday_last wdl_;   // exposition only
    public:
        constexpr month_weekday_last(const chrono::month& m,
                                     const chrono::weekday_last& wdl) noexcept;

        constexpr chrono::month      month()      const noexcept;
        constexpr chrono::weekday_last weekday_last() const noexcept;
        constexpr bool ok() const noexcept;
    };
}

```

`month_weekday_last` represents the last weekday of a month, of an as yet unspecified year. To do this the `month_weekday_last` stores a month and a `weekday_last`.

EXAMPLE

```

constexpr auto mwd
    = February/Tuesday[last];    // mwd is the last Tuesday of February of an as yet unspecified year
static_assert(mwd.month() == February);
static_assert(mwd.weekday_last() == Tuesday[last]);

```

`month_weekday_last` is a trivially copyable and standard-layout class type.

29.8.12.2 Member functions**[time.cal.mwdlast.members]**

```

constexpr month_weekday_last(const chrono::month& m,
                             const chrono::weekday_last& wdl) noexcept;

```

Effects: Initializes `m_` with `m`, and `wdl_` with `wdl`.

```

constexpr chrono::month month() const noexcept;

```

Returns: `m_`.

```

constexpr chrono::weekday_last weekday_last() const noexcept;

```

Returns: `wdl_`.

```

constexpr bool ok() const noexcept;

```

Returns: `m_.ok()` && `wdl_.ok()`.

29.8.12.3 Non-member functions**[time.cal.mwdlast.nonmembers]**

```

constexpr bool operator==(const month_weekday_last& x, const month_weekday_last& y) noexcept;

```

Returns: `x.month() == y.month() && x.weekday_last() == y.weekday_last()`.

```

template<class charT, class traits>
    basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const month_weekday_last& mwdl);

```

Effects: Equivalent to:

```

return os << format(os.getloc(), STatically-WIDEN<charT>("{:L}/{:L}"),
                    mwdl.month(), mwdl.weekday_last());

```

29.8.13 Class year_month**[time.cal.ym]****29.8.13.1 Overview****[time.cal.ym.overview]**

```

namespace std::chrono {
    class year_month {
        chrono::year  y_;      // exposition only
        chrono::month m_;      // exposition only
    };
}

```

```

public:
    year_month() = default;
    constexpr year_month(const chrono::year& y, const chrono::month& m) noexcept;

    constexpr chrono::year year() const noexcept;
    constexpr chrono::month month() const noexcept;

    constexpr year_month& operator+=(const months& dm) noexcept;
    constexpr year_month& operator-=(const months& dm) noexcept;
    constexpr year_month& operator+=(const years& dy) noexcept;
    constexpr year_month& operator-=(const years& dy) noexcept;

    constexpr bool ok() const noexcept;
};

```

`year_month` represents a specific month of a specific year, but with an unspecified day. `year_month` is a field-based time point with a resolution of months. `year_month` meets the *Cpp17EqualityComparable* (Table 28) and *Cpp17LessThanComparable* (Table 29) requirements.

`year_month` is a trivially copyable and standard-layout class type.

29.8.13.2 Member functions

[time.cal.ym.members]

```
constexpr year_month(const chrono::year& y, const chrono::month& m) noexcept;
```

Effects: Initializes `y_` with `y`, and `m_` with `m`.

```
constexpr chrono::year year() const noexcept;
```

Returns: `y_`.

```
constexpr chrono::month month() const noexcept;
```

Returns: `m_`.

```
constexpr year_month& operator+=(const months& dm) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Effects: `*this = *this + dm`.

Returns: `*this`.

```
constexpr year_month& operator-=(const months& dm) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Effects: `*this = *this - dm`.

Returns: `*this`.

```
constexpr year_month& operator+=(const years& dy) noexcept;
```

Effects: `*this = *this + dy`.

Returns: `*this`.

```
constexpr year_month& operator-=(const years& dy) noexcept;
```

Effects: `*this = *this - dy`.

Returns: `*this`.

```
constexpr bool ok() const noexcept;
```

Returns: `y_.ok() && m_.ok()`.

29.8.13.3 Non-member functions

[time.cal.ym.nonmembers]

```
constexpr bool operator==(const year_month& x, const year_month& y) noexcept;
```

Returns: `x.year() == y.year() && x.month() == y.month()`.

```
constexpr strong_ordering operator<=>(const year_month& x, const year_month& y) noexcept;
```

Effects: Equivalent to:

```
if (auto c = x.year() <=> y.year(); c != 0) return c;
return x.month() <=> y.month();
```

```
constexpr year_month operator+(const year_month& ym, const months& dm) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Returns: A `year_month` value `z` such that `z.ok() && z - ym == dm` is true.

Complexity: $\mathcal{O}(1)$ with respect to the value of `dm`.

```
constexpr year_month operator+(const months& dm, const year_month& ym) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Returns: `ym + dm`.

```
constexpr year_month operator-(const year_month& ym, const months& dm) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Returns: `ym - dm`.

```
constexpr months operator-(const year_month& x, const year_month& y) noexcept;
```

Returns:

```
x.year() - y.year() + months{static_cast<int>(unsigned{x.month()}) -
static_cast<int>(unsigned{y.month()})}
```

```
constexpr year_month operator+(const year_month& ym, const years& dy) noexcept;
```

Returns: `(ym.year() + dy) / ym.month()`.

```
constexpr year_month operator+(const years& dy, const year_month& ym) noexcept;
```

Returns: `ym + dy`.

```
constexpr year_month operator-(const year_month& ym, const years& dy) noexcept;
```

Returns: `ym - dy`.

```
template<class charT, class traits>
```

```
basic_ostream<charT, traits>&
```

```
operator<<(basic_ostream<charT, traits>& os, const year_month& ym);
```

Effects: Equivalent to:

```
return os << format(os.getloc(), STatically-WIDEN<charT>("{}/{:L}"),
ym.year(), ym.month());
```

```
template<class charT, class traits, class Alloc = allocator<charT>>
```

```
basic_istream<charT, traits>&
```

```
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
year_month& ym, basic_string<charT, traits, Alloc>* abbrev = nullptr,
minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream `is` into the `year_month` `ym` using the format flags given in the NTCTS `fmt` as specified in 29.13. If the parse fails to decode a valid `year_month`, `is.setstate(ios_base::failbit)` is called and `ym` is not modified. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null.

Returns: `is`.

29.8.14 Class year_month_day

[time.cal.ymd]

29.8.14.1 Overview

[time.cal.ymd.overview]

```

namespace std::chrono {
    class year_month_day {
        chrono::year y_;           // exposition only
        chrono::month m_;          // exposition only
        chrono::day d_;            // exposition only

    public:
        year_month_day() = default;
        constexpr year_month_day(const chrono::year& y, const chrono::month& m,
                                const chrono::day& d) noexcept;
        constexpr year_month_day(const year_month_day_last& ymdl) noexcept;
        constexpr year_month_day(const sys_days& dp) noexcept;
        constexpr explicit year_month_day(const local_days& dp) noexcept;

        constexpr year_month_day& operator+=(const months& m) noexcept;
        constexpr year_month_day& operator-=(const months& m) noexcept;
        constexpr year_month_day& operator+=(const years& y) noexcept;
        constexpr year_month_day& operator-=(const years& y) noexcept;

        constexpr chrono::year year() const noexcept;
        constexpr chrono::month month() const noexcept;
        constexpr chrono::day day() const noexcept;

        constexpr          operator sys_days() const noexcept;
        constexpr explicit operator local_days() const noexcept;
        constexpr bool ok() const noexcept;
    };
}

```

`year_month_day` represents a specific year, month, and day. `year_month_day` is a field-based time point with a resolution of days.

NOTE `year_month_day` supports years- and months-oriented arithmetic, but not days-oriented arithmetic. For the latter, there is a conversion to `sys_days`, which efficiently supports days-oriented arithmetic.

`year_month_day` meets the *Cpp17EqualityComparable* (Table 28) and *Cpp17LessThanComparable* (Table 29) requirements.

`year_month_day` is a trivially copyable and standard-layout class type.

29.8.14.2 Member functions

[time.cal.ymd.members]

```
constexpr year_month_day(const chrono::year& y, const chrono::month& m,
                        const chrono::day& d) noexcept;
```

Effects: Initializes `y_` with `y`, `m_` with `m`, and `d_` with `d`.

```
constexpr year_month_day(const year_month_day_last& ymdl) noexcept;
```

Effects: Initializes `y_` with `ymdl.year()`, `m_` with `ymdl.month()`, and `d_` with `ymdl.day()`.

NOTE This conversion from `year_month_day_last` to `year_month_day` can be more efficient than converting a `year_month_day_last` to a `sys_days`, and then converting that `sys_days` to a `year_month_day`.

```
constexpr year_month_day(const sys_days& dp) noexcept;
```

Effects: Constructs an object of type `year_month_day` that corresponds to the date represented by `dp`.

Remarks: For any value `ymd` of type `year_month_day` for which `ymd.ok()` is true, `ymd == year_month_day{sys_days{ymd}}` is true.

```
constexpr explicit year_month_day(const local_days& dp) noexcept;
```

Effects: Equivalent to constructing with `sys_days{dp.time_since_epoch()}`.

```
constexpr year_month_day& operator+=(const months& m) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Effects: `*this = *this + m`.

Returns: `*this`.

```
constexpr year_month_day& operator-=(const months& m) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Effects: `*this = *this - m`.

Returns: `*this`.

```
constexpr year_month_day& year_month_day::operator+=(const years& y) noexcept;
```

Effects: `*this = *this + y`.

Returns: `*this`.

```
constexpr year_month_day& year_month_day::operator-=(const years& y) noexcept;
```

Effects: `*this = *this - y`.

Returns: `*this`.

```
constexpr chrono::year year() const noexcept;
```

Returns: `y_`.

```
constexpr chrono::month month() const noexcept;
```

Returns: `m_`.

```
constexpr chrono::day day() const noexcept;
```

Returns: `d_`.

```
constexpr operator sys_days() const noexcept;
```

Returns: If `ok()`, returns a `sys_days` holding a count of days from the `sys_days` epoch to `*this` (a negative value if `*this` represents a date prior to the `sys_days` epoch). Otherwise, if `y_.ok() && m_.ok()` is true, returns `sys_days{y_/m_/1d} + (d_ - 1d)`. Otherwise the value returned is unspecified.

Remarks: A `sys_days` in the range `[days{-12687428}, days{11248737}]` which is converted to a `year_month_day` has the same value when converted back to a `sys_days`.

EXAMPLE

```
static_assert(year_month_day{sys_days{2017y/January/0}} == 2016y/December/31);
static_assert(year_month_day{sys_days{2017y/January/31}} == 2017y/January/31);
static_assert(year_month_day{sys_days{2017y/January/32}} == 2017y/February/1);
```

```
constexpr explicit operator local_days() const noexcept;
```

Returns: `local_days{sys_days{*this}.time_since_epoch()}`.

```
constexpr bool ok() const noexcept;
```

Returns: If `y_.ok()` is true, and `m_.ok()` is true, and `d_` is in the range `[1d, (y_/m_/last).day()]`, then returns true; otherwise returns false.

29.8.14.3 Non-member functions

[time.cal.ymd.nonmembers]

```
constexpr bool operator==(const year_month_day& x, const year_month_day& y) noexcept;
```

Returns: `x.year() == y.year() && x.month() == y.month() && x.day() == y.day()`.

```
constexpr strong_ordering operator<=>(const year_month_day& x, const year_month_day& y) noexcept;
```

Effects: Equivalent to:

```

if (auto c = x.year() <=> y.year(); c != 0) return c;
if (auto c = x.month() <=> y.month(); c != 0) return c;
return x.day() <=> y.day();

```

```
constexpr year_month_day operator+(const year_month_day& ymd, const months& dm) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Returns: `(ymd.year() / ymd.month() + dm) / ymd.day()`.

NOTE 1 If `ymd.day()` is in the range `[1d, 28d]`, `ok()` will return `true` for the resultant `year_month_day`.

```
constexpr year_month_day operator+(const months& dm, const year_month_day& ymd) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Returns: `ymd + dm`.

```
constexpr year_month_day operator-(const year_month_day& ymd, const months& dm) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Returns: `ymd + (-dm)`.

```
constexpr year_month_day operator+(const year_month_day& ymd, const years& dy) noexcept;
```

Returns: `(ymd.year() + dy) / ymd.month() / ymd.day()`.

NOTE 2 If `ymd.month()` is February and `ymd.day()` is not in the range `[1d, 28d]`, `ok()` can return `false` for the resultant `year_month_day`.

```
constexpr year_month_day operator+(const years& dy, const year_month_day& ymd) noexcept;
```

Returns: `ymd + dy`.

```
constexpr year_month_day operator-(const year_month_day& ymd, const years& dy) noexcept;
```

Returns: `ymd + (-dy)`.

```
template<class charT, class traits>
```

```
    basic_ostream<charT, traits>&
```

```
    operator<<(basic_ostream<charT, traits>& os, const year_month_day& ymd);
```

Effects: Equivalent to:

```

return os << (ymd.ok() ?
    format(STATICALLY-WIDEN<charT>("{:%F}"), ymd) :
    format(STATICALLY-WIDEN<charT>("{:%F} is not a valid date"), ymd));

```

```
template<class charT, class traits, class Alloc = allocator<charT>>
```

```
    basic_istream<charT, traits>&
```

```
    from_stream(basic_istream<charT, traits>& is, const charT* fmt,
        year_month_day& ymd, basic_string<charT, traits, Alloc>* abbrev = nullptr,
        minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream `is` into the `year_month_day` `ymd` using the format flags given in the NTCTS `fmt` as specified in 29.13. If the parse fails to decode a valid `year_month_day`, `is.setstate(ios_base::failbit)` is called and `ymd` is not modified. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null.

Returns: `is`.

29.8.15 Class `year_month_day_last`

[time.cal.ymdlast]

29.8.15.1 Overview

[time.cal.ymdlast.overview]

```
namespace std::chrono {
```

```
    class year_month_day_last {
```

```
        chrono::year y_; // exposition only
```

```
        chrono::month_day_last mdl_; // exposition only
```

```

public:
    constexpr year_month_day_last(const chrono::year& y,
                                   const chrono::month_day_last& mdl) noexcept;

    constexpr year_month_day_last& operator+=(const months& m) noexcept;
    constexpr year_month_day_last& operator-=(const months& m) noexcept;
    constexpr year_month_day_last& operator+=(const years& y) noexcept;
    constexpr year_month_day_last& operator-=(const years& y) noexcept;

    constexpr chrono::year          year()          const noexcept;
    constexpr chrono::month         month()         const noexcept;
    constexpr chrono::month_day_last month_day_last() const noexcept;
    constexpr chrono::day           day()           const noexcept;

    constexpr          operator sys_days() const noexcept;
    constexpr explicit operator local_days() const noexcept;
    constexpr bool ok() const noexcept;
};
}

```

`year_month_day_last` represents the last day of a specific year and month. `year_month_day_last` is a field-based time point with a resolution of `days`, except that it is restricted to pointing to the last day of a year and month.

NOTE `year_month_day_last` supports `years`- and `months`-oriented arithmetic, but not `days`-oriented arithmetic. For the latter, there is a conversion to `sys_days`, which efficiently supports `days`-oriented arithmetic.

`year_month_day_last` meets the *Cpp17EqualityComparable* (Table 28) and *Cpp17LessThanComparable* (Table 29) requirements.

`year_month_day_last` is a trivially copyable and standard-layout class type.

29.8.15.2 Member functions

[time.cal.ymdlast.members]

```

constexpr year_month_day_last(const chrono::year& y,
                               const chrono::month_day_last& mdl) noexcept;

```

Effects: Initializes `y_` with `y` and `mdl_` with `mdl`.

```

constexpr year_month_day_last& operator+=(const months& m) noexcept;

```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Effects: `*this = *this + m`.

Returns: `*this`.

```

constexpr year_month_day_last& operator-=(const months& m) noexcept;

```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Effects: `*this = *this - m`.

Returns: `*this`.

```

constexpr year_month_day_last& operator+=(const years& y) noexcept;

```

Effects: `*this = *this + y`.

Returns: `*this`.

```

constexpr year_month_day_last& operator-=(const years& y) noexcept;

```

Effects: `*this = *this - y`.

Returns: `*this`.

```

constexpr chrono::year year() const noexcept;

```

Returns: `y_`.

constexpr chrono::month month() const noexcept;

Returns: mdl_.month().

constexpr chrono::month_day_last month_day_last() const noexcept;

Returns: mdl_.

constexpr chrono::day day() const noexcept;

Returns: If ok() is true, returns a day representing the last day of the (year, month) pair represented by *this. Otherwise, the returned value is unspecified.

NOTE This value can be computed on demand.

constexpr operator sys_days() const noexcept;

Returns: sys_days{year()/month()/day()}.

constexpr explicit operator local_days() const noexcept;

Returns: local_days{sys_days{*this}.time_since_epoch()}.

constexpr bool ok() const noexcept;

Returns: y_.ok() && mdl_.ok().

29.8.15.3 Non-member functions

[time.cal.ymdlast.nonmembers]

constexpr bool operator==(const year_month_day_last& x, const year_month_day_last& y) noexcept;

Returns: x.year() == y.year() && x.month_day_last() == y.month_day_last().

constexpr strong_ordering operator<=>(const year_month_day_last& x,
const year_month_day_last& y) noexcept;

Effects: Equivalent to:

```
if (auto c = x.year() <=> y.year(); c != 0) return c;
return x.month_day_last() <=> y.month_day_last();
```

constexpr year_month_day_last

operator+(const year_month_day_last& ymdl, const months& dm) noexcept;

Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.2.4.3).

Returns: (ymdl.year() / ymdl.month() + dm) / last.

constexpr year_month_day_last

operator+(const months& dm, const year_month_day_last& ymdl) noexcept;

Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.2.4.3).

Returns: ymdl + dm.

constexpr year_month_day_last

operator-(const year_month_day_last& ymdl, const months& dm) noexcept;

Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.2.4.3).

Returns: ymdl + (-dm).

constexpr year_month_day_last

operator+(const year_month_day_last& ymdl, const years& dy) noexcept;

Returns: {ymdl.year()+dy, ymdl.month_day_last()}.

constexpr year_month_day_last

operator+(const years& dy, const year_month_day_last& ymdl) noexcept;

Returns: ymdl + dy.

```
constexpr year_month_day_last
operator-(const year_month_day_last& ymdl, const years& dy) noexcept;

Returns: ymdl + (-dy).

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const year_month_day_last& ymdl);

Effects: Equivalent to:

return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{}/{:L}"),
ymdl.year(), ymdl.month_day_last());
```

29.8.16 Class year_month_weekday

[time.cal.ymwd]

29.8.16.1 Overview

[time.cal.ymwd.overview]

```
namespace std::chrono {
class year_month_weekday {
    chrono::year y_;           // exposition only
    chrono::month m_;          // exposition only
    chrono::weekday_indexed wdi_; // exposition only

public:
    year_month_weekday() = default;
    constexpr year_month_weekday(const chrono::year& y, const chrono::month& m,
                                const chrono::weekday_indexed& wdi) noexcept;
    constexpr year_month_weekday(const sys_days& dp) noexcept;
    constexpr explicit year_month_weekday(const local_days& dp) noexcept;

    constexpr year_month_weekday& operator+=(const months& m) noexcept;
    constexpr year_month_weekday& operator-=(const months& m) noexcept;
    constexpr year_month_weekday& operator+=(const years& y) noexcept;
    constexpr year_month_weekday& operator-=(const years& y) noexcept;

    constexpr chrono::year year() const noexcept;
    constexpr chrono::month month() const noexcept;
    constexpr chrono::weekday weekday() const noexcept;
    constexpr unsigned index() const noexcept;
    constexpr chrono::weekday_indexed weekday_indexed() const noexcept;

    constexpr operator sys_days() const noexcept;
    constexpr explicit operator local_days() const noexcept;
    constexpr bool ok() const noexcept;
};
}
```

`year_month_weekday` represents a specific year, month, and n^{th} weekday of the month. `year_month_weekday` is a field-based time-point with a resolution of days.

NOTE `year_month_weekday` supports years- and months-oriented arithmetic, but not days-oriented arithmetic. For the latter, there is a conversion to `sys_days`, which efficiently supports days-oriented arithmetic.

`year_month_weekday` meets the *Cpp17EqualityComparable* (Table 28) requirements.

`year_month_weekday` is a trivially copyable and standard-layout class type.

29.8.16.2 Member functions

[time.cal.ymwd.members]

```
constexpr year_month_weekday(const chrono::year& y, const chrono::month& m,
                             const chrono::weekday_indexed& wdi) noexcept;
```

Effects: Initializes `y_` with `y`, `m_` with `m`, and `wdi_` with `wdi`.

```
constexpr year_month_weekday(const sys_days& dp) noexcept;
```

Effects: Constructs an object of type `year_month_weekday` which corresponds to the date represented by `dp`.

Remarks: For any value `ymwd` of type `year_month_weekday` for which `ymwd.ok()` is `true`, `ymwd == year_month_weekday{sys_days{ymwd}}` is `true`.

`constexpr explicit year_month_weekday(const local_days& dp) noexcept;`

Effects: Equivalent to constructing with `sys_days{dp.time_since_epoch()}`.

`constexpr year_month_weekday& operator+=(const months& m) noexcept;`

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Effects: `*this = *this + m`.

Returns: `*this`.

`constexpr year_month_weekday& operator-=(const months& m) noexcept;`

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Effects: `*this = *this - m`.

Returns: `*this`.

`constexpr year_month_weekday& operator+=(const years& y) noexcept;`

Effects: `*this = *this + y`.

Returns: `*this`.

`constexpr year_month_weekday& operator-=(const years& y) noexcept;`

Effects: `*this = *this - y`.

Returns: `*this`.

`constexpr chrono::year year() const noexcept;`

Returns: `y_`.

`constexpr chrono::month month() const noexcept;`

Returns: `m_`.

`constexpr chrono::weekday weekday() const noexcept;`

Returns: `wdi_.weekday()`.

`constexpr unsigned index() const noexcept;`

Returns: `wdi_.index()`.

`constexpr chrono::weekday_indexed weekday_indexed() const noexcept;`

Returns: `wdi_`.

`constexpr operator sys_days() const noexcept;`

Returns: If `y_.ok() && m_.ok() && wdi_.weekday().ok()`, returns a `sys_days` that represents the date `(index() - 1) * 7` days after the first `weekday()` of `year()/month()`. If `index()` is 0 the returned `sys_days` represents the date 7 days prior to the first `weekday()` of `year()/month()`. Otherwise the returned value is unspecified.

`constexpr explicit operator local_days() const noexcept;`

Returns: `local_days{sys_days{*this}.time_since_epoch()}`.

`constexpr bool ok() const noexcept;`

Returns: If any of `y_.ok()`, `m_.ok()`, or `wdi_.ok()` is `false`, returns `false`. Otherwise, if `*this` represents a valid date, returns `true`. Otherwise, returns `false`.

29.8.16.3 Non-member functions**[time.cal.ymwd.nonmembers]**

```
constexpr bool operator==(const year_month_weekday& x, const year_month_weekday& y) noexcept;
```

Returns:

```
x.year() == y.year() && x.month() == y.month() && x.weekday_indexed() == y.weekday_indexed()
```

```
constexpr year_month_weekday operator+(const year_month_weekday& ymwd, const months& dm) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Returns: (ymwd.year() / ymwd.month() + dm) / ymwd.weekday_indexed().

```
constexpr year_month_weekday operator+(const months& dm, const year_month_weekday& ymwd) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Returns: ymwd + dm.

```
constexpr year_month_weekday operator-(const year_month_weekday& ymwd, const months& dm) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Returns: ymwd + (-dm).

```
constexpr year_month_weekday operator+(const year_month_weekday& ymwd, const years& dy) noexcept;
```

Returns: {ymwd.year()+dy, ymwd.month(), ymwd.weekday_indexed()}.

```
constexpr year_month_weekday operator+(const years& dy, const year_month_weekday& ymwd) noexcept;
```

Returns: ymwd + dy.

```
constexpr year_month_weekday operator-(const year_month_weekday& ymwd, const years& dy) noexcept;
```

Returns: ymwd + (-dy).

```
template<class charT, class traits>
```

```
basic_ostream<charT, traits>&
```

```
operator<<(basic_ostream<charT, traits>& os, const year_month_weekday& ymwd);
```

Effects: Equivalent to:

```
return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{}/{:L}/{:L}"),
    ymwd.year(), ymwd.month(), ymwd.weekday_indexed());
```

29.8.17 Class year_month_weekday_last**[time.cal.ymwdlast]****29.8.17.1 Overview****[time.cal.ymwdlast.overview]**

```
namespace std::chrono {
```

```
class year_month_weekday_last {
```

```
    chrono::year y_; // exposition only
```

```
    chrono::month m_; // exposition only
```

```
    chrono::weekday_last wdl_; // exposition only
```

```
public:
```

```
    constexpr year_month_weekday_last(const chrono::year& y, const chrono::month& m,
        const chrono::weekday_last& wdl) noexcept;
```

```
    constexpr year_month_weekday_last& operator+=(const months& m) noexcept;
```

```
    constexpr year_month_weekday_last& operator-=(const months& m) noexcept;
```

```
    constexpr year_month_weekday_last& operator+=(const years& y) noexcept;
```

```
    constexpr year_month_weekday_last& operator-=(const years& y) noexcept;
```

```
    constexpr chrono::year year() const noexcept;
```

```
    constexpr chrono::month month() const noexcept;
```

```
    constexpr chrono::weekday weekday() const noexcept;
```

```
    constexpr chrono::weekday_last weekday_last() const noexcept;
```

```

    constexpr operator sys_days() const noexcept;
    constexpr explicit operator local_days() const noexcept;
    constexpr bool ok() const noexcept;
};
}

```

`year_month_weekday_last` represents a specific year, month, and last weekday of the month. `year_month_weekday_last` is a field-based time point with a resolution of `days`, except that it is restricted to pointing to the last weekday of a year and month.

NOTE `year_month_weekday_last` supports `years`- and `months`-oriented arithmetic, but not `days`-oriented arithmetic. For the latter, there is a conversion to `sys_days`, which efficiently supports `days`-oriented arithmetic.

`year_month_weekday_last` meets the *Cpp17EqualityComparable* (Table 28) requirements.

`year_month_weekday_last` is a trivially copyable and standard-layout class type.

29.8.17.2 Member functions

[time.cal.ymwdlast.members]

```

constexpr year_month_weekday_last(const chrono::year& y, const chrono::month& m,
                                   const chrono::weekday_last& wdl) noexcept;

```

Effects: Initializes `y_` with `y`, `m_` with `m`, and `wdl_` with `wdl`.

```

constexpr year_month_weekday_last& operator+=(const months& m) noexcept;

```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Effects: `*this = *this + m`.

Returns: `*this`.

```

constexpr year_month_weekday_last& operator-=(const months& m) noexcept;

```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Effects: `*this = *this - m`.

Returns: `*this`.

```

constexpr year_month_weekday_last& operator+=(const years& y) noexcept;

```

Effects: `*this = *this + y`.

Returns: `*this`.

```

constexpr year_month_weekday_last& operator-=(const years& y) noexcept;

```

Effects: `*this = *this - y`.

Returns: `*this`.

```

constexpr chrono::year year() const noexcept;

```

Returns: `y_`.

```

constexpr chrono::month month() const noexcept;

```

Returns: `m_`.

```

constexpr chrono::weekday weekday() const noexcept;

```

Returns: `wdl_.weekday()`.

```

constexpr chrono::weekday_last weekday_last() const noexcept;

```

Returns: `wdl_`.

```

constexpr operator sys_days() const noexcept;

```

Returns: If `ok() == true`, returns a `sys_days` that represents the last `weekday()` of `year()/month()`. Otherwise the returned value is unspecified.

```
constexpr explicit operator local_days() const noexcept;
```

Returns: local_days{sys_days{*this}.time_since_epoch()}.

```
constexpr bool ok() const noexcept;
```

Returns: y_.ok() && m_.ok() && wdl_.ok().

29.8.17.3 Non-member functions

[time.cal.ymwdlast.nonmembers]

```
constexpr bool operator==(const year_month_weekday_last& x,  
                           const year_month_weekday_last& y) noexcept;
```

Returns:

x.year() == y.year() && x.month() == y.month() && x.weekday_last() == y.weekday_last()

```
constexpr year_month_weekday_last
```

```
operator+(const year_month_weekday_last& ymwdl, const months& dm) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Returns: (ymwdl.year() / ymwdl.month() + dm) / ymwdl.weekday_last().

```
constexpr year_month_weekday_last
```

```
operator+(const months& dm, const year_month_weekday_last& ymwdl) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Returns: ymwdl + dm.

```
constexpr year_month_weekday_last
```

```
operator-(const year_month_weekday_last& ymwdl, const months& dm) noexcept;
```

Constraints: If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.2.4.3).

Returns: ymwdl + (-dm).

```
constexpr year_month_weekday_last
```

```
operator+(const year_month_weekday_last& ymwdl, const years& dy) noexcept;
```

Returns: {ymwdl.year()+dy, ymwdl.month(), ymwdl.weekday_last()}.

```
constexpr year_month_weekday_last
```

```
operator+(const years& dy, const year_month_weekday_last& ymwdl) noexcept;
```

Returns: ymwdl + dy.

```
constexpr year_month_weekday_last
```

```
operator-(const year_month_weekday_last& ymwdl, const years& dy) noexcept;
```

Returns: ymwdl + (-dy).

```
template<class charT, class traits>
```

```
basic_ostream<charT, traits>&
```

```
operator<<(basic_ostream<charT, traits>& os, const year_month_weekday_last& ymwdl);
```

Effects: Equivalent to:

```
return os << format(os.getloc(), STatically-WIDEN<charT>("{}/{:L}/{:L}"),  
                    ymwdl.year(), ymwdl.month(), ymwdl.weekday_last());
```

29.8.18 Conventional syntax operators

[time.cal.operators]

A set of overloaded `operator/` functions provides a conventional syntax for the creation of civil calendar dates.

NOTE 1 The year, month, and day are accepted in any of the following 3 orders:

```
year/month/day  
month/day/year  
day/month/year
```

Anywhere a *day* is needed, any of the following can also be specified:

```
last
weekday [i]
weekday [last]
```

NOTE 2 Partial-date types such as `year_month` and `month_day` can be created by not applying the second division operator for any of the three orders. For example:

```
year_month ym = 2015y/April;
month_day md1 = April/4;
month_day md2 = 4d/April;
```

EXAMPLE

```
auto a = 2015/4/4;           // a == int(125)
auto b = 2015y/4/4;          // b == year_month_day{year(2015), month(4), day(4)}
auto c = 2015y/4d/April;     // error: no viable operator/ for first /
auto d = 2015/April/4;       // error: no viable operator/ for first /
```

```
constexpr year_month
operator/(const year& y, const month& m) noexcept;
```

Returns: {y, m}.

```
constexpr year_month
operator/(const year& y, int m) noexcept;
```

Returns: y / month(m).

```
constexpr month_day
operator/(const month& m, const day& d) noexcept;
```

Returns: {m, d}.

```
constexpr month_day
operator/(const month& m, int d) noexcept;
```

Returns: m / day(d).

```
constexpr month_day
operator/(int m, const day& d) noexcept;
```

Returns: month(m) / d.

```
constexpr month_day
operator/(const day& d, const month& m) noexcept;
```

Returns: m / d.

```
constexpr month_day
operator/(const day& d, int m) noexcept;
```

Returns: month(m) / d.

```
constexpr month_day_last
operator/(const month& m, last_spec) noexcept;
```

Returns: month_day_last{m}.

```
constexpr month_day_last
operator/(int m, last_spec) noexcept;
```

Returns: month(m) / last.

```
constexpr month_day_last
operator/(last_spec, const month& m) noexcept;
```

Returns: m / last.

```
constexpr month_day_last
operator/(last_spec, int m) noexcept;
```

Returns: month(m) / last.

```
constexpr month_weekday
operator/(const month& m, const weekday_indexed& wdi) noexcept;
```

Returns: {m, wdi}.

```
constexpr month_weekday
operator/(int m, const weekday_indexed& wdi) noexcept;
```

Returns: month(m) / wdi.

```
constexpr month_weekday
operator/(const weekday_indexed& wdi, const month& m) noexcept;
```

Returns: m / wdi.

```
constexpr month_weekday
operator/(const weekday_indexed& wdi, int m) noexcept;
```

Returns: month(m) / wdi.

```
constexpr month_weekday_last
operator/(const month& m, const weekday_last& wdl) noexcept;
```

Returns: {m, wdl}.

```
constexpr month_weekday_last
operator/(int m, const weekday_last& wdl) noexcept;
```

Returns: month(m) / wdl.

```
constexpr month_weekday_last
operator/(const weekday_last& wdl, const month& m) noexcept;
```

Returns: m / wdl.

```
constexpr month_weekday_last
operator/(const weekday_last& wdl, int m) noexcept;
```

Returns: month(m) / wdl.

```
constexpr year_month_day
operator/(const year_month& ym, const day& d) noexcept;
```

Returns: {ym.year(), ym.month(), d}.

```
constexpr year_month_day
operator/(const year_month& ym, int d) noexcept;
```

Returns: ym / day(d).

```
constexpr year_month_day
operator/(const year& y, const month_day& md) noexcept;
```

Returns: y / md.month() / md.day().

```
constexpr year_month_day
operator/(int y, const month_day& md) noexcept;
```

Returns: year(y) / md.

```
constexpr year_month_day
operator/(const month_day& md, const year& y) noexcept;
```

Returns: y / md.

```
constexpr year_month_day
operator/(const month_day& md, int y) noexcept;
```

Returns: year(y) / md.

```
constexpr year_month_day_last
operator/(const year_month& ym, last_spec) noexcept;
```

Returns: {ym.year(), month_day_last{ym.month()} }.

constexpr year_month_day_last
operator/(const year& y, const month_day_last& mdl) noexcept;
Returns: {y, mdl}.

constexpr year_month_day_last
operator/(int y, const month_day_last& mdl) noexcept;
Returns: year(y) / mdl.

constexpr year_month_day_last
operator/(const month_day_last& mdl, const year& y) noexcept;
Returns: y / mdl.

constexpr year_month_day_last
operator/(const month_day_last& mdl, int y) noexcept;
Returns: year(y) / mdl.

constexpr year_month_weekday
operator/(const year_month& ym, const weekday_indexed& wdi) noexcept;
Returns: {ym.year(), ym.month(), wdi}.

constexpr year_month_weekday
operator/(const year& y, const month_weekday& mwd) noexcept;
Returns: {y, mwd.month(), mwd.weekday_indexed()}.

constexpr year_month_weekday
operator/(int y, const month_weekday& mwd) noexcept;
Returns: year(y) / mwd.

constexpr year_month_weekday
operator/(const month_weekday& mwd, const year& y) noexcept;
Returns: y / mwd.

constexpr year_month_weekday
operator/(const month_weekday& mwd, int y) noexcept;
Returns: year(y) / mwd.

constexpr year_month_weekday_last
operator/(const year_month& ym, const weekday_last& wdl) noexcept;
Returns: {ym.year(), ym.month(), wdl}.

constexpr year_month_weekday_last
operator/(const year& y, const month_weekday_last& mwdl) noexcept;
Returns: {y, mwdl.month(), mwdl.weekday_last()}.

constexpr year_month_weekday_last
operator/(int y, const month_weekday_last& mwdl) noexcept;
Returns: year(y) / mwdl.

constexpr year_month_weekday_last
operator/(const month_weekday_last& mwdl, const year& y) noexcept;
Returns: y / mwdl.

constexpr year_month_weekday_last
operator/(const month_weekday_last& mwdl, int y) noexcept;
Returns: year(y) / mwdl.

29.9 Class template `hh_mm_ss`

[time.hms]

29.9.1 Overview

[time.hms.overview]

```

namespace std::chrono {
    template<class Duration> class hh_mm_ss {
    public:
        static constexpr unsigned fractional_width = see below;
        using precision = see below;

        constexpr hh_mm_ss() noexcept : hh_mm_ss{Duration::zero()} {}
        constexpr explicit hh_mm_ss(Duration d);

        constexpr bool is_negative() const noexcept;
        constexpr chrono::hours hours() const noexcept;
        constexpr chrono::minutes minutes() const noexcept;
        constexpr chrono::seconds seconds() const noexcept;
        constexpr precision subseconds() const noexcept;

        constexpr explicit operator precision() const noexcept;
        constexpr precision to_duration() const noexcept;

    private:
        bool is_neg; // exposition only
        chrono::hours h; // exposition only
        chrono::minutes m; // exposition only
        chrono::seconds s; // exposition only
        precision ss; // exposition only
    };
}

```

The `hh_mm_ss` class template splits a `duration` into a multi-field time structure *hours:minutes:seconds* and possibly *subseconds*, where *subseconds* will be a duration unit based on a non-positive power of 10. The `Duration` template parameter dictates the precision to which the time is split. A `hh_mm_ss` models negative durations with a distinct `is_negative` getter that returns `true` when the input duration is negative. The individual duration fields always return non-negative durations even when `is_negative()` indicates the structure is representing a negative duration.

If `Duration` is not a specialization of `duration`, the program is ill-formed.

29.9.2 Members

[time.hms.members]

```
static constexpr unsigned fractional_width = see below;
```

`fractional_width` is the number of fractional decimal digits represented by `precision`. `fractional_width` has the value of the smallest possible integer in the range $[0, 18]$ such that `precision` will exactly represent all values of `Duration`. If no such value of `fractional_width` exists, then `fractional_width` is 6.

EXAMPLE See Table 100 for some durations, the resulting `fractional_width`, and the formatted fractional second output of `Duration{1}`.

Table 100 — Examples for `fractional_width` [tab:time.hms.width]

Duration	fractional_width	Formatted fractional second output
hours, minutes, and seconds	0	
milliseconds	3	0.001
microseconds	6	0.000001
nanoseconds	9	0.000000001
<code>duration<int, ratio<1, 2>></code>	1	0.5
<code>duration<int, ratio<1, 3>></code>	6	0.333333
<code>duration<int, ratio<1, 4>></code>	2	0.25
<code>duration<int, ratio<1, 5>></code>	1	0.2
<code>duration<int, ratio<1, 6>></code>	6	0.166666
<code>duration<int, ratio<1, 7>></code>	6	0.142857
<code>duration<int, ratio<1, 8>></code>	3	0.125

Table 100 — Examples for fractional_width (continued)

Duration	fractional_width	Formatted fractional second output
duration<int, ratio<1, 9>>	6	0.111111
duration<int, ratio<1, 10>>	1	0.1
duration<int, ratio<756, 625>>	4	0.2096

using precision = see below;

precision is

duration<common_type_t<Duration::rep, seconds::rep>, ratio<1, 10^{fractional_width}>>

constexpr explicit hh_mm_ss(Duration d);

Effects: Constructs an object of type hh_mm_ss which represents the Duration d with precision precision.

- Initializes is_neg with d < Duration::zero().
- Initializes h with duration_cast<chrono::hours>(abs(d)).
- Initializes m with duration_cast<chrono::minutes>(abs(d) - hours()).
- Initializes s with duration_cast<chrono::seconds>(abs(d) - hours() - minutes()).
- If treat_as_floating_point_v<precision::rep> is true, initializes ss with abs(d) - hours() - minutes() - seconds(). Otherwise, initializes ss with duration_cast<precision>(abs(d) - hours() - minutes() - seconds()).

NOTE When precision::rep is integral and precision::period is ratio<1>, subseconds() always returns a value equal to 0s.

Postconditions: If treat_as_floating_point_v<precision::rep> is true, to_duration() returns d, otherwise to_duration() returns duration_cast<precision>(d).

constexpr bool is_negative() const noexcept;

Returns: is_neg.

constexpr chrono::hours hours() const noexcept;

Returns: h.

constexpr chrono::minutes minutes() const noexcept;

Returns: m.

constexpr chrono::seconds seconds() const noexcept;

Returns: s.

constexpr precision subseconds() const noexcept;

Returns: ss.

constexpr precision to_duration() const noexcept;

Returns: If is_neg, returns -(h + m + s + ss), otherwise returns h + m + s + ss.

constexpr explicit operator precision() const noexcept;

Returns: to_duration().

29.9.3 Non-members

[time.hms.nonmembers]

template<class charT, class traits, class Duration>

basic_ostream<charT, traits>&

operator<< (basic_ostream<charT, traits>& os, const hh_mm_ss<Duration>& hms);

Effects: Equivalent to:

return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{:L%T}"), hms);

EXAMPLE

```
for (auto ms : {-4083007ms, 4083007ms, 65745123ms}) {
    hh_mm_ss hms{ms};
    cout << hms << '\n';
}
cout << hh_mm_ss{65745s} << '\n';
```

Produces the output (assuming the "C" locale):

```
-01:08:03.007
01:08:03.007
18:15:45.123
18:15:45
```

29.10 12/24 hours functions

[time.12]

These functions aid in translating between a 12h format time of day and a 24h format time of day.

```
constexpr bool is_am(const hours& h) noexcept;
```

Returns: 0h <= h && h <= 11h.

```
constexpr bool is_pm(const hours& h) noexcept;
```

Returns: 12h <= h && h <= 23h.

```
constexpr hours make12(const hours& h) noexcept;
```

Returns: The 12-hour equivalent of *h* in the range [1h, 12h]. If *h* is not in the range [0h, 23h], the value returned is unspecified.

```
constexpr hours make24(const hours& h, bool is_pm) noexcept;
```

Returns: If *is_pm* is false, returns the 24-hour equivalent of *h* in the range [0h, 11h], assuming *h* represents an ante meridiem hour. Otherwise, returns the 24-hour equivalent of *h* in the range [12h, 23h], assuming *h* represents a post meridiem hour. If *h* is not in the range [1h, 12h], the value returned is unspecified.

29.11 Time zones

[time.zone]

29.11.1 General

[time.zone.general]

[29.11](#) describes an interface for accessing the IANA Time Zone Database^[10] that interoperates with `sys_time` and `local_time`. This interface provides time zone support to both the civil calendar types ([29.8](#)) and to user-defined calendars.

29.11.2 Time zone database

[time.zone.db]

29.11.2.1 Class tzdb

[time.zone.db.tzdb]

```
namespace std::chrono {
    struct tzdb {
        string version;
        vector<time_zone> zones;
        vector<time_zone_link> links;
        vector<leap_second> leap_seconds;

        const time_zone* locate_zone(string_view tz_name) const;
        const time_zone* current_zone() const;
    };
}
```

Each vector in a `tzdb` object is sorted to enable fast lookup.

```
const time_zone* locate_zone(string_view tz_name) const;
```

Returns:

- If `zones` contains an element `tz` for which `tz.name() == tz_name`, a pointer to `tz`;
- otherwise, if `links` contains an element `tz_l` for which `tz_l.name() == tz_name`, then a pointer to the element `tz` of `zones` for which `tz.name() == tz_l.target()`.

NOTE 1 A `time_zone_link` specifies an alternative name for a `time_zone`.

Throws: If a `const time_zone*` cannot be found as described in the *Returns:* element, throws a `runtime_error`.

NOTE 2 On non-exceptional return, the return value is always a pointer to a valid `time_zone`.

```
const time_zone* current_zone() const;
```

Returns: A pointer to the time zone which the computer has set as its local time zone.

29.11.2.2 Class `tzdb_list`

[`time.zone.db.list`]

```
namespace std::chrono {
    class tzdb_list {
    public:
        tzdb_list(const tzdb_list&) = delete;
        tzdb_list& operator=(const tzdb_list&) = delete;

        // unspecified additional constructors

        class const_iterator;

        const tzdb& front() const noexcept;

        const_iterator erase_after(const_iterator p);

        const_iterator begin() const noexcept;
        const_iterator end() const noexcept;

        const_iterator cbegin() const noexcept;
        const_iterator cend() const noexcept;
    };
}
```

The `tzdb_list` database is a singleton; the unique object of type `tzdb_list` can be accessed via the `get_tzdb_list()` function.

NOTE 1 This access is only needed for those applications that need to have long uptimes and have a need to update the time zone database while running. Other applications can implicitly access the `front()` of this list via the read-only namespace scope functions `get_tzdb()`, `locate_zone()`, and `current_zone()`.

The `tzdb_list` object contains a list of `tzdb` objects.

`tzdb_list::const_iterator` is a constant iterator which meets the *Cpp17ForwardIterator* requirements and has a value type of `tzdb`.

```
const tzdb& front() const noexcept;
```

Synchronization: This operation is thread-safe with respect to `reload_tzdb()`.

NOTE 2 `reload_tzdb()` pushes a new `tzdb` onto the front of this container.

Returns: A reference to the first `tzdb` in the container.

```
const_iterator erase_after(const_iterator p);
```

Preconditions: The iterator following `p` is dereferenceable.

Effects: Erases the `tzdb` referred to by the iterator following `p`.

Postconditions: No pointers, references, or iterators are invalidated except those referring to the erased `tzdb`.

NOTE 3 It is not possible to erase the `tzdb` referred to by `begin()`.

Returns: An iterator pointing to the element following the one that was erased, or `end()` if no such element exists.

Throws: Nothing.

```
const_iterator begin() const noexcept;
```

Returns: An iterator referring to the first `tzdb` in the container.

```
const_iterator end() const noexcept;
```

Returns: An iterator referring to the position one past the last `tzdb` in the container.

```
const_iterator cbegin() const noexcept;
```

Returns: `begin()`.

```
const_iterator cend() const noexcept;
```

Returns: `end()`.

29.11.2.3 Time zone database access

[time.zone.db.access]

```
tzdb_list& get_tzdb_list();
```

Effects: If this is the first access to the time zone database, initializes the database. If this call initializes the database, the resulting database will be a `tzdb_list` holding a single initialized `tzdb`.

Synchronization: It is safe to call this function from multiple threads at one time.

Returns: A reference to the database.

Throws: `runtime_error` if for any reason a reference cannot be returned to a valid `tzdb_list` containing one or more valid `tzdb`s.

```
const tzdb& get_tzdb();
```

Returns: `get_tzdb_list().front()`.

```
const time_zone* locate_zone(string_view tz_name);
```

Returns: `get_tzdb().locate_zone(tz_name)`.

NOTE The time zone database will be initialized if this is the first reference to the database.

```
const time_zone* current_zone();
```

Returns: `get_tzdb().current_zone()`.

29.11.2.4 Remote time zone database support

[time.zone.db.remote]

The local time zone database is that supplied by the implementation when the program first accesses the database, for example via `current_zone()`. While the program is running, the implementation may choose to update the time zone database. This update shall not impact the program in any way unless the program calls the functions in this subclause. This potentially updated time zone database is referred to as the *remote time zone database*.

```
const tzdb& reload_tzdb();
```

Effects: This function first checks the version of the remote time zone database. If the versions of the local and remote databases are the same, there are no effects. Otherwise the remote database is pushed to the front of the `tzdb_list` accessed by `get_tzdb_list()`.

Synchronization: This function is thread-safe with respect to `get_tzdb_list().front()` and `get_tzdb_list().erase_after()`.

Postconditions: No pointers, references, or iterators are invalidated.

Returns: `get_tzdb_list().front()`.

Throws: `runtime_error` if for any reason a reference cannot be returned to a valid `tzdb`.

```
string remote_version();
```

Returns: The latest remote database version.

NOTE This can be compared with `get_tzdb().version` to discover if the local and remote databases are equivalent.

29.11.3 Exception classes**[time.zone.exception]****29.11.3.1 Class nonexistent_local_time****[time.zone.exception.nonexist]**

```

namespace std::chrono {
    class nonexistent_local_time : public runtime_error {
    public:
        template<class Duration>
            nonexistent_local_time(const local_time<Duration>& tp, const local_info& i);
    };
}

```

`nonexistent_local_time` is thrown when an attempt is made to convert a non-existent `local_time` to a `sys_time` without specifying `choose::earliest` or `choose::latest`.

```

template<class Duration>
nonexistent_local_time(const local_time<Duration>& tp, const local_info& i);

```

Preconditions: `i.result == local_info::nonexistent` is true.

Effects: Initializes the base class with a sequence of `char` equivalent to that produced by `os.str()` initialized as shown below:

```

ostreamstream os;
os << tp << " is in a gap between\n"
    << local_seconds{i.first.end.time_since_epoch()} + i.first.offset << ' '
    << i.first.abbrev << " and\n"
    << local_seconds{i.second.begin.time_since_epoch()} + i.second.offset << ' '
    << i.second.abbrev
    << " which are both equivalent to\n"
    << i.first.end << " UTC";

```

EXAMPLE

```

#include <chrono>
#include <iostream>

int main() {
    using namespace std::chrono;
    try {
        auto zt = zoned_time{"America/New_York",
                             local_days{Sunday[2]/March/2016} + 2h + 30min};
    } catch (const nonexistent_local_time& e) {
        std::cout << e.what() << '\n';
    }
}

```

Produces the output:

```

2016-03-13 02:30:00 is in a gap between
2016-03-13 02:00:00 EST and
2016-03-13 03:00:00 EDT which are both equivalent to
2016-03-13 07:00:00 UTC

```

29.11.3.2 Class ambiguous_local_time**[time.zone.exception.ambig]**

```

namespace std::chrono {
    class ambiguous_local_time : public runtime_error {
    public:
        template<class Duration>
            ambiguous_local_time(const local_time<Duration>& tp, const local_info& i);
    };
}

```

`ambiguous_local_time` is thrown when an attempt is made to convert an ambiguous `local_time` to a `sys_time` without specifying `choose::earliest` or `choose::latest`.

```

template<class Duration>
ambiguous_local_time(const local_time<Duration>& tp, const local_info& i);

```

Preconditions: `i.result == local_info::ambiguous` is true.

Effects: Initializes the base class with a sequence of `char` equivalent to that produced by `os.str()` initialized as shown below:

```
ostreamstream os;
os << tp << " is ambiguous. It could be\n"
  << tp << ' ' << i.first.abbrev << " == "
  << tp - i.first.offset << " UTC or\n"
  << tp << ' ' << i.second.abbrev << " == "
  << tp - i.second.offset << " UTC";
```

EXAMPLE

```
#include <chrono>
#include <iostream>

int main() {
    using namespace std::chrono;
    try {
        auto zt = zoned_time{"America/New_York",
                             local_days{Sunday[1]/November/2016} + 1h + 30min};
    } catch (const ambiguous_local_time& e) {
        std::cout << e.what() << '\n';
    }
}
```

Produces the output:

```
2016-11-06 01:30:00 is ambiguous. It could be
2016-11-06 01:30:00 EDT == 2016-11-06 05:30:00 UTC or
2016-11-06 01:30:00 EST == 2016-11-06 06:30:00 UTC
```

29.11.4 Information classes

[time.zone.info]

29.11.4.1 Class `sys_info`

[time.zone.info.sys]

```
namespace std::chrono {
    struct sys_info {
        sys_seconds    begin;
        sys_seconds    end;
        seconds        offset;
        minutes        save;
        string          abbrev;
    };
}
```

A `sys_info` object can be obtained from the combination of a `time_zone` and either a `sys_time` or `local_time`. It can also be obtained from a `zoned_time`, which is effectively a pair of a `time_zone` and `sys_time`.

NOTE This type provides a low-level interface to time zone information. Typical conversions from `sys_time` to `local_time` will use this class implicitly, not explicitly.

The `begin` and `end` data members indicate that, for the associated `time_zone` and `time_point`, the `offset` and `abbrev` are in effect in the range `[begin,end)`. This information can be used to efficiently iterate the transitions of a `time_zone`.

The `offset` data member indicates the UTC offset in effect for the associated `time_zone` and `time_point`. The relationship between `local_time` and `sys_time` is:

$$\text{offset} = \text{local\_time} - \text{sys\_time}$$

The `save` data member is extra information not normally needed for conversion between `local_time` and `sys_time`. If `save != 0min`, this `sys_info` is said to be on “daylight saving” time, and `offset - save` provides a non-authoritative suggestion of the offset this `time_zone` would use if it were off daylight saving time. A correct offset for the `time_zone` off daylight saving time can be obtained by querying the `time_zone` with a `time_point` that returns a `sys_info` where `save == 0min`. There is no guarantee what `time_point` (if any) returns such a `sys_info` except that it is guaranteed not to be in the range `[begin,end)` (if `save != 0min` for this `sys_info`).

The `abbrev` data member indicates the current abbreviation used for the associated `time_zone` and `time_point`. Abbreviations are not unique among the `time_zones`, and so one cannot reliably map abbreviations back to a `time_zone` and UTC offset.

```
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const sys_info& r);
```

Effects: Streams out the `sys_info` object `r` in an unspecified format.

Returns: `os`.

29.11.4.2 Class `local_info`

[time.zone.info.local]

```
namespace std::chrono {
struct local_info {
    static constexpr int unique      = 0;
    static constexpr int nonexistent = 1;
    static constexpr int ambiguous   = 2;

    int result;
    sys_info first;
    sys_info second;
};
}
```

NOTE This type provides a low-level interface to time zone information. Typical conversions from `local_time` to `sys_time` will use this class implicitly, not explicitly.

Describes the result of converting a `local_time` to a `sys_time` as follows:

- When a `local_time` to `sys_time` conversion is unique, `result == unique`, `first` will be filled out with the correct `sys_info`, and `second` will be zero-initialized.
- If the conversion stems from a nonexistent `local_time` then `result == nonexistent`, `first` will be filled out with the `sys_info` that ends just prior to the `local_time`, and `second` will be filled out with the `sys_info` that begins just after the `local_time`.
- If the conversion stems from an ambiguous `local_time`, then `result == ambiguous`, `first` will be filled out with the `sys_info` that ends just after the `local_time`, and `second` will be filled out with the `sys_info` that starts just before the `local_time`.

```
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const local_info& r);
```

Effects: Streams out the `local_info` object `r` in an unspecified format.

Returns: `os`.

29.11.5 Class `time_zone`

[time.zone.timezone]

29.11.5.1 Overview

[time.zone.overview]

```
namespace std::chrono {
class time_zone {
public:
    time_zone(time_zone&&) = default;
    time_zone& operator=(time_zone&&) = default;
    // unspecified additional constructors

    string_view name() const noexcept;

    template<class Duration> sys_info get_info(const sys_time<Duration>& st) const;
    template<class Duration> local_info get_info(const local_time<Duration>& tp) const;

    template<class Duration>
        sys_time<common_type_t<Duration, seconds>>
        to_sys(const local_time<Duration>& tp) const;

    template<class Duration>
        sys_time<common_type_t<Duration, seconds>>
        to_sys(const local_time<Duration>& tp, choose z) const;
};
}
```

```

    template<class Duration>
        local_time<common_type_t<Duration, seconds>>
            to_local(const sys_time<Duration>& tp) const;
};
}

```

A `time_zone` represents all time zone transitions for a specific geographic area. `time_zone` construction is unspecified, and performed as part of database initialization.

NOTE `const time_zone` objects can be accessed via functions such as `locate_zone`.

29.11.5.2 Member functions

[time.zone.members]

```
string_view name() const noexcept;
```

Returns: The name of the `time_zone`.

EXAMPLE "America/New_York".

```

template<class Duration>
    sys_info get_info(const sys_time<Duration>& st) const;

```

Returns: A `sys_info` `i` for which `st` is in the range `[i.begin, i.end)`.

```

template<class Duration>
    local_info get_info(const local_time<Duration>& tp) const;

```

Returns: A `local_info` for `tp`.

```

template<class Duration>
    sys_time<common_type_t<Duration, seconds>>
        to_sys(const local_time<Duration>& tp) const;

```

Returns: A `sys_time` that is at least as fine as `seconds`, and will be finer if the argument `tp` has finer precision. This `sys_time` is the UTC equivalent of `tp` according to the rules of this `time_zone`.

Throws: If the conversion from `tp` to a `sys_time` is ambiguous, throws `ambiguous_local_time`. If the `tp` represents a non-existent time between two UTC `time_points`, throws `nonexistent_local_time`.

```

template<class Duration>
    sys_time<common_type_t<Duration, seconds>>
        to_sys(const local_time<Duration>& tp, choose z) const;

```

Returns: A `sys_time` that is at least as fine as `seconds`, and will be finer if the argument `tp` has finer precision. This `sys_time` is the UTC equivalent of `tp` according to the rules of this `time_zone`. If the conversion from `tp` to a `sys_time` is ambiguous, returns the earlier `sys_time` if `z == choose::earliest`, and returns the later `sys_time` if `z == choose::latest`. If the `tp` represents a non-existent time between two UTC `time_points`, then the two UTC `time_points` will be the same, and that UTC `time_point` will be returned.

```

template<class Duration>
    local_time<common_type_t<Duration, seconds>>
        to_local(const sys_time<Duration>& tp) const;

```

Returns: The `local_time` associated with `tp` and this `time_zone`.

29.11.5.3 Non-member functions

[time.zone.nonmembers]

```
bool operator==(const time_zone& x, const time_zone& y) noexcept;
```

Returns: `x.name() == y.name()`.

```
strong_ordering operator<=>(const time_zone& x, const time_zone& y) noexcept;
```

Returns: `x.name() <=> y.name()`.

29.11.6 Class template `zoned_traits`

[time.zone.zonedtraits]

```

namespace std::chrono {
    template<class T> struct zoned_traits {};
}

```

`zoned_traits` provides a means for customizing the behavior of `zoned_time<Duration, TimeZonePtr>` for the `zoned_time` default constructor, and constructors taking `string_view`. A specialization for `const time_zone*` is provided by the implementation:

```
namespace std::chrono {
    template<> struct zoned_traits<const time_zone*> {
        static const time_zone* default_zone();
        static const time_zone* locate_zone(string_view name);
    };
}
```

```
static const time_zone* default_zone();
```

Returns: `std::chrono::locate_zone("UTC")`.

```
static const time_zone* locate_zone(string_view name);
```

Returns: `std::chrono::locate_zone(name)`.

29.11.7 Class template `zoned_time`

[time.zone.zonedtime]

29.11.7.1 Overview

[time.zone.zonedtime.overview]

```
namespace std::chrono {
    template<class Duration, class TimeZonePtr = const time_zone*>
    class zoned_time {
    public:
        using duration = common_type_t<Duration, seconds>;

    private:
        TimeZonePtr zone_; // exposition only
        sys_time<duration> tp_; // exposition only

        using traits = zoned_traits<TimeZonePtr>; // exposition only

    public:
        zoned_time();
        zoned_time(const zoned_time&) = default;
        zoned_time& operator=(const zoned_time&) = default;

        zoned_time(const sys_time<Duration>& st);
        explicit zoned_time(TimeZonePtr z);
        explicit zoned_time(string_view name);

        template<class Duration2>
            zoned_time(const zoned_time<Duration2, TimeZonePtr>& y);

        zoned_time(TimeZonePtr z, const sys_time<Duration>& st);
        zoned_time(string_view name, const sys_time<Duration>& st);

        zoned_time(TimeZonePtr z, const local_time<Duration>& tp);
        zoned_time(string_view name, const local_time<Duration>& tp);
        zoned_time(TimeZonePtr z, const local_time<Duration>& tp, choose c);
        zoned_time(string_view name, const local_time<Duration>& tp, choose c);

        template<class Duration2, class TimeZonePtr2>
            zoned_time(TimeZonePtr z, const zoned_time<Duration2, TimeZonePtr2>& y);
        template<class Duration2, class TimeZonePtr2>
            zoned_time(TimeZonePtr z, const zoned_time<Duration2, TimeZonePtr2>& y, choose);

        template<class Duration2, class TimeZonePtr2>
            zoned_time(string_view name, const zoned_time<Duration2, TimeZonePtr2>& y);
        template<class Duration2, class TimeZonePtr2>
            zoned_time(string_view name, const zoned_time<Duration2, TimeZonePtr2>& y, choose c);

        zoned_time& operator=(const sys_time<Duration>& st);
        zoned_time& operator=(const local_time<Duration>& lt);
    };
}
```

```

operator sys_time<duration>() const;
explicit operator local_time<duration>() const;

TimeZonePtr      get_time_zone() const;
local_time<duration> get_local_time() const;
sys_time<duration>  get_sys_time() const;
sys_info         get_info() const;
};

zoned_time() -> zoned_time<seconds>;

template<class Duration>
zoned_time(sys_time<Duration>)
-> zoned_time<common_type_t<Duration, seconds>>;

template<class TimeZonePtrOrName>
using time-zone-representation = // exposition only
    conditional_t<is_convertible_v<TimeZonePtrOrName, string_view>,
        const time_zone*,
        remove_cvref_t<TimeZonePtrOrName>>;

template<class TimeZonePtrOrName>
zoned_time(TimeZonePtrOrName&&)
-> zoned_time<seconds, time-zone-representation<TimeZonePtrOrName>>;

template<class TimeZonePtrOrName, class Duration>
zoned_time(TimeZonePtrOrName&&, sys_time<Duration>)
-> zoned_time<common_type_t<Duration, seconds>,
    time-zone-representation<TimeZonePtrOrName>>;

template<class TimeZonePtrOrName, class Duration>
zoned_time(TimeZonePtrOrName&&, local_time<Duration>,
    choose = choose::earliest)
-> zoned_time<common_type_t<Duration, seconds>,
    time-zone-representation<TimeZonePtrOrName>>;

template<class Duration, class TimeZonePtrOrName, class TimeZonePtr2>
zoned_time(TimeZonePtrOrName&&, zoned_time<Duration, TimeZonePtr2>,
    choose = choose::earliest)
-> zoned_time<common_type_t<Duration, seconds>,
    time-zone-representation<TimeZonePtrOrName>>;
}

```

`zoned_time` represents a logical pairing of a `time_zone` and a `time_point` with precision `Duration`. `zoned_time<Duration>` maintains the invariant that it always refers to a valid time zone and represents a point in time that exists and is not ambiguous in that time zone.

If `Duration` is not a specialization of `chrono::duration`, the program is ill-formed.

Every constructor of `zoned_time` that accepts a `string_view` as its first parameter does not participate in class template argument deduction (12.2.2.9).

29.11.7.2 Constructors

[time.zone.zonedtime.ctor]

```
zoned_time();
```

Constraints: `traits::default_zone()` is a well-formed expression.

Effects: Initializes `zone_` with `traits::default_zone()` and default constructs `tp_`.

```
zoned_time(const sys_time<Duration>& st);
```

Constraints: `traits::default_zone()` is a well-formed expression.

Effects: Initializes `zone_` with `traits::default_zone()` and `tp_` with `st`.

```
explicit zoned_time(TimeZonePtr z);
```

Preconditions: `z` refers to a time zone.

Effects: Initializes `zone_` with `std::move(z)` and default constructs `tp_`.

```
explicit zoned_time(string_view name);
```

Constraints: `traits::locate_zone(string_view{})` is a well-formed expression and `zoned_time` is constructible from the return type of `traits::locate_zone(string_view{})`.

Effects: Initializes `zone_` with `traits::locate_zone(name)` and default constructs `tp_`.

```
template<class Duration2>
```

```
zoned_time(const zoned_time<Duration2, TimeZonePtr>& y);
```

Constraints: `is_convertible_v<sys_time<Duration2>, sys_time<Duration>>` is true.

Effects: Initializes `zone_` with `y.zone_` and `tp_` with `y.tp_`.

```
zoned_time(TimeZonePtr z, const sys_time<Duration>& st);
```

Preconditions: `z` refers to a time zone.

Effects: Initializes `zone_` with `std::move(z)` and `tp_` with `st`.

```
zoned_time(string_view name, const sys_time<Duration>& st);
```

Constraints: `zoned_time` is constructible from the return type of `traits::locate_zone(name)` and `st`.

Effects: Equivalent to construction with `{traits::locate_zone(name), st}`.

```
zoned_time(TimeZonePtr z, const local_time<Duration>& tp);
```

Constraints:

```
is_convertible_v<
    decltype(declval<TimeZonePtr>()->to_sys(local_time<Duration>{})),
    sys_time<duration>>
```

is true.

Preconditions: `z` refers to a time zone.

Effects: Initializes `zone_` with `std::move(z)` and `tp_` with `zone_->to_sys(tp)`.

```
zoned_time(string_view name, const local_time<Duration>& tp);
```

Constraints: `zoned_time` is constructible from the return type of `traits::locate_zone(name)` and `tp`.

Effects: Equivalent to construction with `{traits::locate_zone(name), tp}`.

```
zoned_time(TimeZonePtr z, const local_time<Duration>& tp, choose c);
```

Constraints:

```
is_convertible_v<
    decltype(declval<TimeZonePtr>()->to_sys(local_time<Duration>{}, choose::earliest)),
    sys_time<duration>>
```

is true.

Preconditions: `z` refers to a time zone.

Effects: Initializes `zone_` with `std::move(z)` and `tp_` with `zone_->to_sys(tp, c)`.

```
zoned_time(string_view name, const local_time<Duration>& tp, choose c);
```

Constraints: `zoned_time` is constructible from the return type of `traits::locate_zone(name)`, `local_time<Duration>`, and `choose`.

Effects: Equivalent to construction with `{traits::locate_zone(name), tp, c}`.

```
template<class Duration2, class TimeZonePtr2>
```

```
zoned_time(TimeZonePtr z, const zoned_time<Duration2, TimeZonePtr2>& y);
```

Constraints: `is_convertible_v<sys_time<Duration2>, sys_time<Duration>>` is true.

Preconditions: `z` refers to a valid time zone.

Effects: Initializes `zone_` with `std::move(z)` and `tp_` with `y.tp_`.

```
template<class Duration2, class TimeZonePtr2>
```

```
zoned_time(TimeZonePtr z, const zoned_time<Duration2, TimeZonePtr2>& y, choose);
```

Constraints: `is_convertible_v<sys_time<Duration2>, sys_time<Duration>>` is true.

Preconditions: `z` refers to a valid time zone.

Effects: Equivalent to construction with `{z, y}`.

NOTE 1 The `choose` parameter has no effect.

```
template<class Duration2, class TimeZonePtr2>
```

```
zoned_time(string_view name, const zoned_time<Duration2, TimeZonePtr2>& y);
```

Constraints: `zoned_time` is constructible from the return type of `traits::locate_zone(name)` and the type `zoned_time<Duration2, TimeZonePtr2>`.

Effects: Equivalent to construction with `{traits::locate_zone(name), y}`.

```
template<class Duration2, class TimeZonePtr2>
```

```
zoned_time(string_view name, const zoned_time<Duration2, TimeZonePtr2>& y, choose c);
```

Constraints: `zoned_time` is constructible from the return type of `traits::locate_zone(name)`, the type `zoned_time<Duration2, TimeZonePtr2>`, and the type `choose`.

Effects: Equivalent to construction with `{traits::locate_zone(name), y, c}`.

NOTE 2 The `choose` parameter has no effect.

29.11.7.3 Member functions

[`time.zone.zonedtime.members`]

```
zoned_time& operator=(const sys_time<Duration>& st);
```

Effects: After assignment, `get_sys_time() == st`. This assignment has no effect on the return value of `get_time_zone()`.

Returns: `*this`.

```
zoned_time& operator=(const local_time<Duration>& lt);
```

Effects: After assignment, `get_local_time() == lt`. This assignment has no effect on the return value of `get_time_zone()`.

Returns: `*this`.

```
operator sys_time<duration>() const;
```

Returns: `get_sys_time()`.

```
explicit operator local_time<duration>() const;
```

Returns: `get_local_time()`.

```
TimeZonePtr get_time_zone() const;
```

Returns: `zone_`.

```
local_time<duration> get_local_time() const;
```

Returns: `zone_>to_local(tp_)`.

```
sys_time<duration> get_sys_time() const;
```

Returns: `tp_`.

```
sys_info get_info() const;
```

Returns: `zone_>get_info(tp_)`.

29.11.7.4 Non-member functions**[time.zone.zonedtime.nonmembers]**

```
template<class Duration1, class Duration2, class TimeZonePtr>
bool operator==(const zoned_time<Duration1, TimeZonePtr>& x,
               const zoned_time<Duration2, TimeZonePtr>& y);
```

Returns: `x.zone_ == y.zone_ && x.tp_ == y.tp_`.

```
template<class charT, class traits, class Duration, class TimeZonePtr>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os,
          const zoned_time<Duration, TimeZonePtr>& t);
```

Effects: Equivalent to:

```
return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{:L%F %T %Z}"), t);
```

29.11.8 Class leap_second**[time.zone.leap]****29.11.8.1 Overview****[time.zone.leap.overview]**

```
namespace std::chrono {
class leap_second {
public:
    leap_second(const leap_second&) = default;
    leap_second& operator=(const leap_second&) = default;

    // unspecified additional constructors

    constexpr sys_seconds date() const noexcept;
    constexpr seconds value() const noexcept;
};
}
```

Objects of type `leap_second` representing the date and value of the leap second insertions are constructed and stored in the time zone database when initialized.

EXAMPLE

```
for (auto& l : get_tzdb().leap_seconds)
    if (l <= 2018y/March/17d)
        cout << l.date() << ": " << l.value() << '\n';
```

Produces the output:

```
1972-07-01 00:00:00: 1s
1973-01-01 00:00:00: 1s
1974-01-01 00:00:00: 1s
1975-01-01 00:00:00: 1s
1976-01-01 00:00:00: 1s

29.11.8.2 Member functions

[time.zone.leap.members]

constexpr sys_seconds date() const noexcept;

Returns: The date and time at which the leap second was inserted.

constexpr seconds value() const noexcept;

Returns: +1s to indicate a positive leap second or -1s to indicate a negative leap second.

NOTE All leap seconds inserted up through 2022 were positive leap seconds.

29.11.8.3 Non-member functions

[time.zone.leap.nonmembers]

constexpr bool operator==(const leap_second& x, const leap_second& y) noexcept;

Returns: x.date() == y.date().

constexpr strong_ordering operator<=>(const leap_second& x, const leap_second& y) noexcept;

Returns: x.date() <=> y.date().

template<class Duration>

constexpr bool operator==(const leap_second& x, const sys_time<Duration>& y) noexcept;

Returns: x.date() == y.

template<class Duration>

constexpr bool operator<(const leap_second& x, const sys_time<Duration>& y) noexcept;

Returns: x.date() < y.

template<class Duration>

constexpr bool operator<(const sys_time<Duration>& x, const leap_second& y) noexcept;

Returns: x < y.date().

template<class Duration>

constexpr bool operator>(const leap_second& x, const sys_time<Duration>& y) noexcept;

Returns: y < x.

template<class Duration>

constexpr bool operator>(const sys_time<Duration>& x, const leap_second& y) noexcept;

Returns: y < x.

template<class Duration>

constexpr bool operator<=(const leap_second& x, const sys_time<Duration>& y) noexcept;

Returns: !(y < x).

template<class Duration>

constexpr bool operator<=(const sys_time<Duration>& x, const leap_second& y) noexcept;

Returns: !(y < x).

template<class Duration>

constexpr bool operator>=(const leap_second& x, const sys_time<Duration>& y) noexcept;

Returns: !(x < y).

template<class Duration>

constexpr bool operator>=(const sys_time<Duration>& x, const leap_second& y) noexcept;

Returns: !(x < y).

template<class Duration>

requires three_way_comparable_with<sys_seconds, sys_time<Duration>>

constexpr auto operator<=>(const leap_second& x, const sys_time<Duration>& y) noexcept;

Returns: x.date() <=> y.

29.11.9 Class `time_zone_link`**[time.zone.link]****29.11.9.1 Overview****[time.zone.link.overview]**

```

namespace std::chrono {
    class time_zone_link {
    public:
        time_zone_link(time_zone_link&&) = default;
        time_zone_link& operator=(time_zone_link&&) = default;

        // unspecified additional constructors

        string_view name() const noexcept;
        string_view target() const noexcept;
    };
}

```

A `time_zone_link` specifies an alternative name for a `time_zone`. `time_zone_links` are constructed when the time zone database is initialized.

29.11.9.2 Member functions**[time.zone.link.members]**

```
string_view name() const noexcept;
```

Returns: The alternative name for the time zone.

```
string_view target() const noexcept;
```

Returns: The name of the `time_zone` for which this `time_zone_link` provides an alternative name.

29.11.9.3 Non-member functions**[time.zone.link.nonmembers]**

```
bool operator==(const time_zone_link& x, const time_zone_link& y) noexcept;
```

Returns: `x.name() == y.name()`.

```
strong_ordering operator<=>(const time_zone_link& x, const time_zone_link& y) noexcept;
```

Returns: `x.name() <=> y.name()`.

29.12 Formatting**[time.format]**

Each `formatter` (22.14.6) specialization in the `chrono` library (29.2) meets the *Formatter* requirements (22.14.6.1). The `parse` member functions of these formatters interpret the format specification as a *chrono-format-spec* according to the following syntax:

```

chrono-format-spec:
    fill-and-alignopt widthopt precisionopt Lopt chrono-specsopt

chrono-specs:
    conversion-spec
    chrono-specs conversion-spec
    chrono-specs literal-char

literal-char:
    any character other than {, }, or %

conversion-spec:
    % modifieropt type

modifier: one of
    E O

type: one of
    a A b B c C d D e F g G h H i j m M n
    p q Q r R S t T u U V w W x X y Y z Z %

```

The productions *fill-and-align*, *width*, and *precision* are described in 22.14.2. Giving a *precision* specification in the *chrono-format-spec* is valid only for types that are specializations of `std::chrono::duration` for which the nested *typedef-name* `rep` denotes a floating-point type. For all other types, an exception of type `format_error` is thrown if the *chrono-format-spec* contains a *precision* specification. All ordinary multibyte characters represented by *literal-char* are copied unchanged to the output.

A *formatting locale* is an instance of `locale` used by a formatting function, defined as

- the "C" locale if the L option is not present in *chrono-format-spec*, otherwise
- the locale passed to the formatting function if any, otherwise
- the global locale.

Each conversion specifier *conversion-spec* is replaced by appropriate characters as described in Table 101; the formats specified in ISO 8601-1:2019 shall be used where so described. Some of the conversion specifiers depend on the formatting locale. If the string literal encoding is a Unicode encoding form and the locale is among an implementation-defined set of locales, each replacement that depends on the locale is performed as if the replacement character sequence is converted to the string literal encoding. If the formatted object does not contain the information the conversion specifier refers to, an exception of type `format_error` is thrown.

The result of formatting a `std::chrono::duration` instance holding a negative value, or an `hh_mm_ss` object `h` for which `h.is_negative()` is `true`, is equivalent to the output of the corresponding positive value, with a *STATICALLY-WIDEN*`<charT>("-")` character sequence placed before the replacement of the initial conversion specifier.

EXAMPLE 1

```
cout << format("{:%T}", -10'000s);           // prints: -02:46:40
cout << format("{:%H:%M:%S}", -10'000s);    // prints: -02:46:40
cout << format("minutes {:%M}, hours %H, seconds %S", -10'000s);
                                           // prints: minutes -46, hours 02, seconds 40
```

Unless explicitly requested, the result of formatting a chrono type does not contain time zone abbreviation and time zone offset information. If the information is available, the conversion specifiers `%Z` and `%z` will format this information (respectively).

NOTE If the information is not available and a `%Z` or `%z` conversion specifier appears in the *chrono-format-spec*, an exception of type `format_error` is thrown, as described above.

If the type being formatted does not contain the information that the format flag needs, an exception of type `format_error` is thrown.

EXAMPLE 2 A `duration` does not contain enough information to format as a `weekday`.

However, if a flag refers to a “time of day” (e.g., `%H`, `%I`, `%p`, etc.), then a specialization of `duration` is interpreted as the time of day elapsed since midnight.

Table 101 — Meaning of conversion specifiers [tab:time.format.spec]

Specifier	Replacement
<code>%a</code>	The locale’s abbreviated weekday name. If the value does not contain a valid weekday, an exception of type <code>format_error</code> is thrown.
<code>%A</code>	The locale’s full weekday name. If the value does not contain a valid weekday, an exception of type <code>format_error</code> is thrown.
<code>%b</code>	The locale’s abbreviated month name. If the value does not contain a valid month, an exception of type <code>format_error</code> is thrown.
<code>%B</code>	The locale’s full month name. If the value does not contain a valid month, an exception of type <code>format_error</code> is thrown.
<code>%c</code>	The locale’s date and time representation. The modified command <code>%Ec</code> produces the locale’s alternate date and time representation.
<code>%C</code>	The year divided by 100 using floored division. If the result is a single decimal digit, it is prefixed with 0. The modified command <code>%EC</code> produces the locale’s alternative representation of the century.
<code>%d</code>	The day of month as a decimal number. If the result is a single decimal digit, it is prefixed with 0. The modified command <code>%Od</code> produces the locale’s alternative representation.
<code>%D</code>	Equivalent to <code>%m/%d/%y</code> .
<code>%e</code>	The day of month as a decimal number. If the result is a single decimal digit, it is prefixed with a space. The modified command <code>%Oe</code> produces the locale’s alternative representation.
<code>%F</code>	Equivalent to <code>%Y-%m-%d</code> .
<code>%g</code>	The last two decimal digits of the calendar year as specified in ISO 8601-1:2019 for the week calendar. If the result is a single digit it is prefixed by 0.

Table 101 — Meaning of conversion specifiers (continued)

Specifier	Replacement
%G	The calendar year as a decimal number, as specified in ISO 8601-1:2019 for the week calendar. If the result is less than four digits it is left-padded with 0 to four digits.
%h	Equivalent to %b.
%H	The hour (24-hour clock) as a decimal number. If the result is a single digit, it is prefixed with 0. The modified command %OH produces the locale's alternative representation.
%I	The hour (12-hour clock) as a decimal number. If the result is a single digit, it is prefixed with 0. The modified command %OI produces the locale's alternative representation.
%j	If the type being formatted is a specialization of duration , the decimal number of days without padding. Otherwise, the day of the year as a decimal number. January 1 is 001. If the result is less than three digits, it is left-padded with 0 to three digits.
%m	The month as a decimal number. Jan is 01. If the result is a single digit, it is prefixed with 0. The modified command %Om produces the locale's alternative representation.
%M	The minute as a decimal number. If the result is a single digit, it is prefixed with 0. The modified command %OM produces the locale's alternative representation.
%n	A new-line character.
%p	The locale's equivalent of the AM/PM designations associated with a 12-hour clock.
%q	The duration's unit suffix as specified in 29.5.11.
%Q	The duration's numeric value (as if extracted via <code>.count()</code>).
%r	The locale's 12-hour clock time.
%R	Equivalent to %H:%M.
%S	Seconds as a decimal number. If the number of seconds is less than 10, the result is prefixed with 0. If the precision of the input cannot be exactly represented with seconds, then the format is a decimal floating-point number with a fixed format and a precision matching that of the precision of the input (or to a microseconds precision if the conversion to floating-point decimal seconds cannot be made within 18 fractional digits). The character for the decimal point is localized according to the locale. The modified command %OS produces the locale's alternative representation.
%t	A horizontal-tab character.
%T	Equivalent to %H:%M:%S.
%u	The calendar day of week as a decimal number (1-7), as specified in ISO 8601-1:2019, where Monday is 1. The modified command %Ou produces the locale's alternative representation.
%U	The week number of the year as a decimal number. The first Sunday of the year is the first day of week 01. Days of the same year prior to that are in week 00. If the result is a single digit, it is prefixed with 0. The modified command %OU produces the locale's alternative representation.
%V	The calendar week of year as a decimal number, as specified in ISO 8601-1:2019 for the week calendar. If the result is a single digit, it is prefixed with 0. The modified command %OV produces the locale's alternative representation.
%w	The weekday as a decimal number (0-6), where Sunday is 0. The modified command %Ow produces the locale's alternative representation.
%W	The week number of the year as a decimal number. The first Monday of the year is the first day of week 01. Days of the same year prior to that are in week 00. If the result is a single digit, it is prefixed with 0. The modified command %OW produces the locale's alternative representation.
%x	The locale's date representation. The modified command %Ex produces the locale's alternate date representation.
%X	The locale's time representation. The modified command %EX produces the locale's alternate time representation.
%y	The last two decimal digits of the year. If the result is a single digit it is prefixed by 0. The modified command %Oy produces the locale's alternative representation. The modified command %Ey produces the locale's alternative representation of offset from %EC (year only).

Table 101 — Meaning of conversion specifiers (continued)

Specifier	Replacement
%Y	The year as a decimal number. If the result is less than four digits it is left-padded with 0 to four digits. The modified command %EY produces the locale's alternative full year representation.
%z	The offset from UTC as specified in ISO 8601-1:2019, 5.3.4.1. For example -0430 refers to 4 hours 30 minutes behind UTC. If the offset is zero, +0000 is used. The modified commands %Ez and %Oz insert a : between the hours and minutes: -04:30. If the offset information is not available, an exception of type <code>format_error</code> is thrown.
%Z	The time zone abbreviation. If the time zone abbreviation is not available, an exception of type <code>format_error</code> is thrown.
%%	A % character.

If the *chrono-specs* is omitted, the chrono object is formatted as if by streaming it to `basic_ostring-stream<charT> os` with the formatting locale imbued and copying `os.str()` through the output iterator of the context with additional padding and adjustments as specified by the format specifiers.

EXAMPLE 3

```
string s = format("{:=>8}", 42ms);           // value of s is "====42ms"
```

```
template<class Duration, class charT>
struct formatter<chrono::sys_time<Duration>, charT>;
```

Remarks: If %Z is used, it is replaced with *STATICALLY-WIDEN*<charT>("UTC"). If %z (or a modified variant of %z) is used, an offset of 0min is formatted.

```
template<class Duration, class charT>
struct formatter<chrono::utc_time<Duration>, charT>;
```

Remarks: If %Z is used, it is replaced with *STATICALLY-WIDEN*<charT>("UTC"). If %z (or a modified variant of %z) is used, an offset of 0min is formatted. If the argument represents a time during a positive leap second insertion, and if a seconds field is formatted, the integral portion of that format is *STATICALLY-WIDEN*<charT>("60").

```
template<class Duration, class charT>
struct formatter<chrono::tai_time<Duration>, charT>;
```

Remarks: If %Z is used, it is replaced with *STATICALLY-WIDEN*<charT>("TAI"). If %z (or a modified variant of %z) is used, an offset of 0min is formatted. The date and time formatted are equivalent to those formatted by a `sys_time` initialized with

```
sys_time<Duration>{tp.time_since_epoch()} -
(sys_days{1970y/January/1} - sys_days{1958y/January/1})
```

```
template<class Duration, class charT>
struct formatter<chrono::gps_time<Duration>, charT>;
```

Remarks: If %Z is used, it is replaced with *STATICALLY-WIDEN*<charT>("GPS"). If %z (or a modified variant of %z) is used, an offset of 0min is formatted. The date and time formatted are equivalent to those formatted by a `sys_time` initialized with

```
sys_time<Duration>{tp.time_since_epoch()} +
(sys_days{1980y/January/Sunday[1]} - sys_days{1970y/January/1})
```

```
template<class Duration, class charT>
struct formatter<chrono::file_time<Duration>, charT>;
```

Remarks: If %Z is used, it is replaced with *STATICALLY-WIDEN*<charT>("UTC"). If %z (or a modified variant of %z) is used, an offset of 0min is formatted. The date and time formatted are equivalent to those formatted by a `sys_time` initialized with `clock_cast<system_clock>(t)`, or by a `utc_time` initialized with `clock_cast<utc_clock>(t)`, where `t` is the first argument to `format`.

```
template<class Duration, class charT>
struct formatter<chrono::local_time<Duration>, charT>;
```

Remarks: If %Z, %z, or a modified version of %z is used, an exception of type `format_error` is thrown.

```

template<class Duration> struct local-time-format-t {           // exposition only
    local_time<Duration> time;                                   // exposition only
    const string* abbrev;                                       // exposition only
    const seconds* offset_sec;                                   // exposition only
};

template<class Duration>
    local-time-format-t<Duration>
    local_time_format(local_time<Duration> time, const string* abbrev = nullptr,
                      const seconds* offset_sec = nullptr);

    Returns: {time, abbrev, offset_sec}.

template<class Duration, class charT>
    struct formatter<chrono::local-time-format-t<Duration>, charT>;

    Let f be a local-time-format-t<Duration> object passed to formatter::format.

    Remarks: If %Z is used, it is replaced with *f.abbrev if f.abbrev is not a null pointer value. If %Z is
    used and f.abbrev is a null pointer value, an exception of type format_error is thrown. If %z (or a
    modified variant of %z) is used, it is formatted with the value of *f.offset_sec if f.offset_sec is
    not a null pointer value. If %z (or a modified variant of %z) is used and f.offset_sec is a null pointer
    value, then an exception of type format_error is thrown.

template<class Duration, class TimeZonePtr, class charT>
    struct formatter<chrono::zoned_time<Duration, TimeZonePtr>, charT>
    : formatter<chrono::local-time-format-t<Duration>, charT> {
    template<class FormatContext>
        typename FormatContext::iterator
        format(const chrono::zoned_time<Duration, TimeZonePtr>& tp, FormatContext& ctx) const;
};

template<class FormatContext>
    typename FormatContext::iterator
    format(const chrono::zoned_time<Duration, TimeZonePtr>& tp, FormatContext& ctx) const;

    Effects: Equivalent to:

        sys_info info = tp.get_info();
        return formatter<chrono::local-time-format-t<Duration>, charT>::
            format({tp.get_local_time(), &info.abbrev, &info.offset}, ctx);

```

29.13 Parsing

[time.parse]

Each `parse` overload specified in this subclause calls `from_stream` unqualified, so as to enable argument dependent lookup (6.5.4). In the following paragraphs, let `is` denote an object of type `basic_istream<charT, traits>` and let `I` be `basic_istream<charT, traits>&`, where `charT` and `traits` are template parameters in that context.

Recommended practice: Implementations should make it difficult to accidentally store or use a manipulator that may contain a dangling reference to a format string, for example by making the manipulators produced by `parse` immovable and preventing stream extraction into an lvalue of such a manipulator type.

```

template<class charT, class Parsable>
    unspecified
    parse(const charT* fmt, Parsable& tp);
template<class charT, class traits, class Alloc, class Parsable>
    unspecified
    parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp);

```

Let `F` be `fmt` for the first overload and `fmt.c_str()` for the second overload. Let `traits` be `char_traits<charT>` for the first overload.

Constraints: The expression

```
from_stream(declval<basic_istream<charT, traits>&>(), F, tp)
```

is well-formed when treated as an unevaluated operand (7.2.3).

Returns: A manipulator such that the expression `is >> parse(fmt, tp)` has type `I`, has value `is`, and calls `from_stream(is, F, tp)`.

```
template<class charT, class traits, class Alloc, class Parsable>
```

```
    unspecified
```

```
    parse(const charT* fmt, Parsable& tp,
          basic_string<charT, traits, Alloc>& abbrev);
```

```
template<class charT, class traits, class Alloc, class Parsable>
```

```
    unspecified
```

```
    parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp,
          basic_string<charT, traits, Alloc>& abbrev);
```

Let *F* be *fmt* for the first overload and *fmt.c_str()* for the second overload.

Constraints: The expression

```
from_stream(declval<basic_istream<charT, traits>&>(), F, tp, addressof(abbrev))
```

is well-formed when treated as an unevaluated operand (7.2.3).

Returns: A manipulator such that the expression is `>> parse(fmt, tp, abbrev)` has type *I*, has value *is*, and calls `from_stream(is, F, tp, addressof(abbrev))`.

```
template<class charT, class Parsable>
```

```
    unspecified
```

```
    parse(const charT* fmt, Parsable& tp, minutes& offset);
```

```
template<class charT, class traits, class Alloc, class Parsable>
```

```
    unspecified
```

```
    parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp,
          minutes& offset);
```

Let *F* be *fmt* for the first overload and *fmt.c_str()* for the second overload. Let *traits* be `char_traits<charT>` and *Alloc* be `allocator<charT>` for the first overload.

Constraints: The expression

```
from_stream(declval<basic_istream<charT, traits>&>(),
            F, tp,
            declval<basic_string<charT, traits, Alloc>*>(),
            &offset)
```

is well-formed when treated as an unevaluated operand (7.2.3).

Returns: A manipulator such that the expression is `>> parse(fmt, tp, offset)` has type *I*, has value *is*, and calls:

```
from_stream(is,
            F, tp,
            static_cast<basic_string<charT, traits, Alloc>*>(nullptr),
            &offset)
```

```
template<class charT, class traits, class Alloc, class Parsable>
```

```
    unspecified
```

```
    parse(const charT* fmt, Parsable& tp,
          basic_string<charT, traits, Alloc>& abbrev, minutes& offset);
```

```
template<class charT, class traits, class Alloc, class Parsable>
```

```
    unspecified
```

```
    parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp,
          basic_string<charT, traits, Alloc>& abbrev, minutes& offset);
```

Let *F* be *fmt* for the first overload and *fmt.c_str()* for the second overload.

Constraints: The expression

```
from_stream(declval<basic_istream<charT, traits>&>(),
            F, tp, addressof(abbrev), &offset)
```

is well-formed when treated as an unevaluated operand (7.2.3).

Returns: A manipulator such that the expression is `>> parse(fmt, tp, abbrev, offset)` has type *I*, has value *is*, and calls `from_stream(is, F, tp, addressof(abbrev), &offset)`.

All `from_stream` overloads behave as unformatted input functions, except that they have an unspecified effect on the value returned by subsequent calls to `basic_istream<>::gcount()`. Each overload takes a format string containing ordinary characters and flags which have special meaning. Each flag begins with a %. Some flags can be modified by *E* or *O*. During parsing each flag interprets characters as parts of date and

time types according to Table 102. Some flags can be modified by a width parameter given as a positive decimal integer called out as *N* below which governs how many characters are parsed from the stream in interpreting the flag. All characters in the format string that are not represented in Table 102, except for whitespace, are parsed unchanged from the stream. A whitespace character matches zero or more whitespace characters in the input stream.

If the type being parsed cannot represent the information that the format flag refers to, `is.setstate(ios_base::failbit)` is called.

EXAMPLE A `duration` cannot represent a `weekday`.

However, if a flag refers to a “time of day” (e.g., `%H`, `%I`, `%p`, etc.), then a specialization of `duration` is parsed as the time of day elapsed since midnight.

If the `from_stream` overload fails to parse everything specified by the format string, or if insufficient information is parsed to specify a complete duration, time point, or calendrical data structure, `setstate(ios_base::failbit)` is called on the `basic_istream`.

Table 102 — Meaning of parse flags [tab:time.parse.spec]

Flag	Parsed value
<code>%a</code>	The locale’s full or abbreviated case-insensitive weekday name.
<code>%A</code>	Equivalent to <code>%a</code> .
<code>%b</code>	The locale’s full or abbreviated case-insensitive month name.
<code>%B</code>	Equivalent to <code>%b</code> .
<code>%c</code>	The locale’s date and time representation. The modified command <code>%Ec</code> interprets the locale’s alternate date and time representation.
<code>%C</code>	The century as a decimal number. The modified command <code>%NC</code> specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 2. Leading zeroes are permitted but not required. The modified command <code>%EC</code> interprets the locale’s alternative representation of the century.
<code>%d</code>	The day of the month as a decimal number. The modified command <code>%Nd</code> specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 2. Leading zeroes are permitted but not required. The modified command <code>%Od</code> interprets the locale’s alternative representation of the day of the month.
<code>%D</code>	Equivalent to <code>%m/%d/%y</code> .
<code>%e</code>	Equivalent to <code>%d</code> and can be modified like <code>%d</code> .
<code>%F</code>	Equivalent to <code>%Y-%m-%d</code> . If modified with a width <i>N</i> , the width is applied to only <code>%Y</code> .
<code>%g</code>	The last two decimal digits of the calendar year, as specified in ISO 8601-1:2019 for the week calendar. The modified command <code>%Ng</code> specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 2. Leading zeroes are permitted but not required.
<code>%G</code>	The calendar year as a decimal number, as specified in ISO 8601-1:2019 for the week calendar. The modified command <code>%NG</code> specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 4. Leading zeroes are permitted but not required.
<code>%h</code>	Equivalent to <code>%b</code> .
<code>%H</code>	The hour (24-hour clock) as a decimal number. The modified command <code>%NH</code> specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 2. Leading zeroes are permitted but not required. The modified command <code>%OH</code> interprets the locale’s alternative representation.
<code>%I</code>	The hour (12-hour clock) as a decimal number. The modified command <code>%NI</code> specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 2. Leading zeroes are permitted but not required. The modified command <code>%OI</code> interprets the locale’s alternative representation.
<code>%j</code>	If the type being parsed is a specialization of <code>duration</code> , a decimal number of <code>days</code> . Otherwise, the day of the year as a decimal number. January 1 is 1. In either case, the modified command <code>%Nj</code> specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 3. Leading zeroes are permitted but not required.

Table 102 — Meaning of parse flags (continued)

Flag	Parsed value
%m	The month as a decimal number. January is 1. The modified command %Nm specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 2. Leading zeroes are permitted but not required. The modified command %Om interprets the locale's alternative representation.
%M	The minutes as a decimal number. The modified command %NM specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 2. Leading zeroes are permitted but not required. The modified command %OM interprets the locale's alternative representation.
%n	Matches one whitespace character. NOTE %n, %t, and a space can be combined to match a wide range of whitespace patterns. For example, "%n " matches one or more whitespace characters, and "%n%t%t" matches one to three whitespace characters.
%p	The locale's equivalent of the AM/PM designations associated with a 12-hour clock.
%r	The locale's 12-hour clock time.
%R	Equivalent to %H:%M.
%S	The seconds as a decimal number. The modified command %NS specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 2 if the input time has a precision convertible to seconds. Otherwise the default width is determined by the decimal precision of the input and the field is interpreted as a long double in a fixed format. If encountered, the locale determines the decimal point character. Leading zeroes are permitted but not required. The modified command %OS interprets the locale's alternative representation.
%t	Matches zero or one whitespace characters.
%T	Equivalent to %H:%M:%S.
%u	The calendar day of week as a decimal number (1-7), as specified in ISO 8601-1:2019, where Monday is 1. The modified command %Nu specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 1. Leading zeroes are permitted but not required.
%U	The week number of the year as a decimal number. The first Sunday of the year is the first day of week 01. Days of the same year prior to that are in week 00. The modified command %NU specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 2. Leading zeroes are permitted but not required. The modified command %OU interprets the locale's alternative representation.
%V	The calendar week of year as a decimal number, as specified in ISO 8601-1:2019 for the week calendar. The modified command %NV specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 2. Leading zeroes are permitted but not required.
%w	The weekday as a decimal number (0-6), where Sunday is 0. The modified command %Nw specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 1. Leading zeroes are permitted but not required. The modified command %Ow interprets the locale's alternative representation.
%W	The week number of the year as a decimal number. The first Monday of the year is the first day of week 01. Days of the same year prior to that are in week 00. The modified command %NW specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 2. Leading zeroes are permitted but not required. The modified command %OW interprets the locale's alternative representation.
%x	The locale's date representation. The modified command %Ex interprets the locale's alternate date representation.
%X	The locale's time representation. The modified command %EX interprets the locale's alternate time representation.

Table 102 — Meaning of parse flags (continued)

Flag	Parsed value
%y	The last two decimal digits of the year. If the century is not otherwise specified (e.g., with %C), values in the range [69, 99] are presumed to refer to the years 1969 to 1999, and values in the range [00, 68] are presumed to refer to the years 2000 to 2068. The modified command %Ny specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 2. Leading zeroes are permitted but not required. The modified commands %Ey and %Oy interpret the locale's alternative representation.
%Y	The year as a decimal number. The modified command %NY specifies the maximum number of characters to read. If <i>N</i> is not specified, the default is 4. Leading zeroes are permitted but not required. The modified command %EY interprets the locale's alternative representation.
%z	The offset from UTC in the format [+ -]hh[mm]. For example -0430 refers to 4 hours 30 minutes behind UTC, and 04 refers to 4 hours ahead of UTC. The modified commands %Ez and %Oz parse a : between the hours and minutes and render leading zeroes on the hour field optional: [+ -]h[h][:mm]. For example -04:30 refers to 4 hours 30 minutes behind UTC, and 4 refers to 4 hours ahead of UTC.
%Z	The time zone abbreviation or name. A single word is parsed. This word can only contain characters from the basic character set (5.3) that are alphanumeric, or one of ' _ ', ' / ', ' - ', or ' + '.
%%	A % character is extracted.

29.14 Header <ctime> synopsis

[ctime.syn]

```

#define NULL see 17.2.3
#define CLOCKS_PER_SEC see below
#define TIME_UTC see below

namespace std {
    using size_t = see 17.2.4;
    using clock_t = see below;
    using time_t = see below;

    struct timespec;
    struct tm;

    clock_t clock();
    double difftime(time_t time1, time_t time0);
    time_t mktime(tm* timeptr);
    time_t time(time_t* timer);
    int timespec_get(timespec* ts, int base);
    char* asctime(const tm* timeptr);
    char* ctime(const time_t* timer);
    tm* gmtime(const time_t* timer);
    tm* localtime(const time_t* timer);
    size_t strftime(char* s, size_t maxsize, const char* format, const tm* timeptr);
}

```

The contents of the header <ctime> are the same as the C standard library header <time.h>.²³⁹

The functions asctime, ctime, gmtime, and localtime are not required to avoid data races (16.4.6.10).

See also ISO/IEC 9899:2018, 7.27.

²³⁹) strftime supports the C conversion specifiers C, D, e, F, g, G, h, r, R, t, T, u, V, and z, and the modifiers E and O.

30 Localization library

[localization]

30.1 General

[localization.general]

This Clause describes components that C++ programs may use to encapsulate (and therefore be more portable when confronting) cultural differences. The locale facility includes internationalization support for character classification and string collation, numeric, monetary, and date/time formatting and parsing, and message retrieval.

The following subclauses describe components for locales themselves, the standard facets, and facilities from the C library, as summarized in [Table 103](#).

Table 103 — Localization library summary [tab:localization.summary]

	Subclause	Header
30.3	Locales	<locale>
30.4	Standard locale categories	
30.5	C library locales	<ctype>

30.2 Header <locale> synopsis

[locale.syn]

```

namespace std {
    // 30.3.1, locale
    class locale;

    class moneypunct;
template<class charT, bool Intl = false>
    class moneypunct_byname;

// 30.4.8, message retrieval
class messages_base;
template<class charT> class messages;
template<class charT> class messages_byname;
}

```

The header `<locale>` defines classes and declares functions that encapsulate and manipulate the information peculiar to a locale.²⁴⁰

30.3 Locales

[locales]

30.3.1 Class locale

[locale]

30.3.1.1 General

[locale.general]

```

namespace std {
    class locale {
    public:
        // types
        class facet;
        class id;
        using category = int;
        static const category // values assigned here are for exposition only
            none = 0,
            collate = 0x010, ctype = 0x020,
            monetary = 0x040, numeric = 0x080,
            time = 0x100, messages = 0x200,
            all = collate | ctype | monetary | numeric | time | messages;

        // construct/copy/destroy
        locale() noexcept;
        locale(const locale& other) noexcept;
        explicit locale(const char* std_name);
        explicit locale(const string& std_name);
        locale(const locale& other, const char* std_name, category);
    };
}

```

²⁴⁰ In this subclause, the type name `tm` is an incomplete type that is defined in `<ctime>` (29.14).

```

    locale(const locale& other, const string& std_name, category);
    template<class Facet> locale(const locale& other, Facet* f);
    locale(const locale& other, const locale& one, category);
    ~locale(); // not virtual
    const locale& operator=(const locale& other) noexcept;
    template<class Facet> locale combine(const locale& other) const;

    // locale operations
    string name() const;

    bool operator==(const locale& other) const;

    template<class charT, class traits, class Allocator>
        bool operator()(const basic_string<charT, traits, Allocator>& s1,
                        const basic_string<charT, traits, Allocator>& s2) const;

    // global locale objects
    static locale global(const locale&);
    static const locale& classic();
};
}

```

Class `locale` implements a type-safe polymorphic set of facets, indexed by facet *type*. In other words, a facet has a dual role: in one sense, it's just a class interface; at the same time, it's an index into a locale's set of facets.

Access to the facets of a `locale` is via two function templates, `use_facet<>` and `has_facet<>`.

EXAMPLE An `ostream operator<<` can be implemented as:²⁴¹

```

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<< (basic_ostream<charT, traits>& s, Date d) {
    typename basic_ostream<charT, traits>::sentry cerberos(s);
    if (cerberos) {
        tm tmbuf; d.extract(tmbuf);
        bool failed =
            use_facet<time_put<charT, ostreambuf_iterator<charT, traits>>>>(
                s.getloc()).put(s, s, s.fill(' '), tmbuf, 'x').failed();
        if (failed)
            s.setstate(s.badbit); // can throw
    }
    return s;
}

```

In the call to `use_facet<Facet>(loc)`, the type argument chooses a facet, making available all members of the named type. If `Facet` is not present in a locale, it throws the standard exception `bad_cast`. A C++ program can check if a locale implements a particular facet with the function template `has_facet<Facet>()`. User-defined facets may be installed in a locale, and used identically as may standard facets.

NOTE All locale semantics are accessed via `use_facet<>` and `has_facet<>`, except that:

- A member operator template

```
operator()(const basic_string<C, T, A>&, const basic_string<C, T, A>&)
```

is provided so that a locale can be used as a predicate argument to the standard collections, to collate strings.

- Convenient global interfaces are provided for traditional `ctype` functions such as `isdigit()` and `isspace()`, so that given a locale object `loc` a C++ program can call `isspace(c, loc)`. (This eases upgrading existing extractors (31.7.5.3).)

Once a facet reference is obtained from a locale object by calling `use_facet<>`, that reference remains usable, and the results from member functions of it may be cached and re-used, as long as some locale object refers to that facet.

In successive calls to a locale facet member function on a facet object installed in the same locale, the returned result shall be identical.

²⁴¹) Note that in the call to `put`, the stream is implicitly converted to an `ostreambuf_iterator<charT, traits>`.

A **locale** constructed from a name string (such as "POSIX"), or from parts of two named locales, has a name; all others do not. Named locales may be compared for equality; an unnamed locale is equal only to (copies of) itself. For an unnamed locale, `locale::name()` returns the string "*".

Whether there is one global locale object for the entire program or one global locale object per thread is implementation-defined. Implementations should provide one global locale object per thread. If there is a single global locale object for the entire program, implementations are not required to avoid data races on it (16.4.6.10).

30.3.1.2 Types

[locale.types]

30.3.1.2.1 Type `locale::category`

[locale.category]

```
using category = int;
```

Valid **category** values include the **locale** member bitmask elements **collate**, **ctype**, **monetary**, **numeric**, **time**, and **messages**, each of which represents a single locale category. In addition, **locale** member bitmask constant **none** is defined as zero and represents no category. And **locale** member bitmask constant **all** is defined such that the expression

```
(collate | ctype | monetary | numeric | time | messages | all) == all
```

is **true**, and represents the union of all categories. Further, the expression $(X \mid Y)$, where X and Y each represent a single category, represents the union of the two categories.

locale member functions expecting a **category** argument require one of the **category** values defined above, or the union of two or more such values. Such a **category** value identifies a set of locale categories. Each locale category, in turn, identifies a set of locale facets, including at least those shown in Table 104.

Table 104 — Locale category facets [tab:locale.category.facets]

Category	Includes facets
collate	<code>collate<char></code> , <code>collate<wchar_t></code>
ctype	<code>ctype<char></code> , <code>ctype<wchar_t></code> <code>codecvt<char, char, mbstate_t></code> <code>codecvt<char16_t, char8_t, mbstate_t></code> <code>codecvt<char32_t, char8_t, mbstate_t></code> <code>codecvt<wchar_t, char, mbstate_t></code>
monetary	<code>moneypunct<char></code> , <code>moneypunct<wchar_t></code> <code>moneypunct<char, true></code> , <code>moneypunct<wchar_t, true></code> <code>money_get<char></code> , <code>money_get<wchar_t></code> <code>money_put<char></code> , <code>money_put<wchar_t></code>
numeric	<code>numput<char></code> , <code>numput<wchar_t></code> <code>num_get<char></code> , <code>num_get<wchar_t></code> <code>num_put<char></code> , <code>num_put<wchar_t></code>
time	<code>time_get<char></code> , <code>time_get<wchar_t></code> <code>time_put<char></code> , <code>time_put<wchar_t></code>
messages	<code>messages<char></code> , <code>messages<wchar_t></code>

For any locale `loc` either constructed, or returned by `locale::classic()`, and any facet **Facet** shown in Table 104, `has_facet<Facet>(loc)` is **true**. Each locale member function which takes a `locale::category` argument operates on the corresponding set of facets.

An implementation is required to provide those specializations for facet templates identified as members of a category, and for those shown in Table 105.

The provided implementation of members of facets `num_get<charT>` and `num_put<charT>` calls `use_facet<F>(1)` only for facet F of types `numput<charT>` and `ctype<charT>`, and for locale l the value obtained by calling member `getloc()` on the `ios_base&` argument to these functions.

In declarations of facets, a template parameter with name `InputIterator` or `OutputIterator` indicates the set of all possible specializations on parameters that meet the *Cpp17InputIterator* requirements or *Cpp17OutputIterator* requirements, respectively (25.3). A template parameter with name C represents the set of types containing `char`, `wchar_t`, and any other implementation-defined character types that meet the

Table 105 — Required specializations [tab:locale.spec]

Category	Includes facets
collate	collate_byname<char>, collate_byname<wchar_t>
ctype	ctype_byname<char>, ctype_byname<wchar_t> codecvt_byname<char, char, mbstate_t> codecvt_byname<char16_t, char8_t, mbstate_t> codecvt_byname<char32_t, char8_t, mbstate_t> codecvt_byname<wchar_t, char, mbstate_t>
monetary	moneypunct_byname<char, International> moneypunct_byname<wchar_t, International> money_get<C, InputIterator> money_put<C, OutputIterator>
numeric	numpunct_byname<char>, numpunct_byname<wchar_t> num_get<C, InputIterator>, num_put<C, OutputIterator>
time	time_get<char, InputIterator> time_get_byname<char, InputIterator> time_get<wchar_t, InputIterator> time_get_byname<wchar_t, InputIterator> time_put<char, OutputIterator> time_put_byname<char, OutputIterator> time_put<wchar_t, OutputIterator> time_put_byname<wchar_t, OutputIterator>
messages	messages_byname<char>, messages_byname<wchar_t>

requirements for a character on which any of the `istream` components can be instantiated. A template parameter with name `International` represents the set of all possible specializations on a `bool` parameter.

30.3.1.2.2 Class `locale::facet`

[locale.facet]

```
namespace std {
    class locale::facet {
    protected:
        explicit facet(size_t refs = 0);
        virtual ~facet();
        facet(const facet&) = delete;
        void operator=(const facet&) = delete;
    };
}
```

Class `facet` is the base class for locale feature sets. A class is a *facet* if it is publicly derived from another facet, or if it is a class derived from `locale::facet` and contains a publicly accessible declaration as follows:²⁴²

```
static ::std::locale::id id;
```

Template parameters in this Clause which are required to be facets are those named `Facet` in declarations. A program that passes a type that is *not* a facet, or a type that refers to a volatile-qualified facet, as an (explicit or deduced) template parameter to a locale function expecting a facet, is ill-formed. A const-qualified facet is a valid template argument to any locale function that expects a `Facet` template parameter.

The `refs` argument to the constructor is used for lifetime management. For `refs == 0`, the implementation performs `delete static_cast<locale::facet*>(f)` (where `f` is a pointer to the facet) when the last `locale` object containing the facet is destroyed; for `refs == 1`, the implementation never destroys the facet.

Constructors of all facets defined in this Clause take such an argument and pass it along to their `facet` base class constructor. All one-argument constructors defined in this Clause are *explicit*, preventing their participation in implicit conversions.

For some standard facets a standard “..._byname” class, derived from it, implements the virtual function semantics equivalent to that facet of the locale constructed by `locale(const char*)` with the same name.

²⁴²) This is a complete list of requirements; there are no other requirements. Thus, a facet class need not have a public copy constructor, assignment, default constructor, destructor, etc.

Each such facet provides a constructor that takes a `const char*` argument, which names the locale, and a `refs` argument, which is passed to the base class constructor. Each such facet also provides a constructor that takes a `string` argument `str` and a `refs` argument, which has the same effect as calling the first constructor with the two arguments `str.c_str()` and `refs`. If there is no “`...byname`” version of a facet, the base class implements named locale semantics itself by reference to other facets.

30.3.1.2.3 Class `locale::id`

[locale.id]

```
namespace std {
    class locale::id {
    public:
        id();
        void operator=(const id&) = delete;
        id(const id&) = delete;
    };
}
```

The class `locale::id` provides identification of a locale facet interface, used as an index for lookup and to encapsulate initialization.

NOTE Because facets are used by iostreams, potentially while static constructors are running, it is not possible for their initialization to depend on programmed static initialization. One initialization strategy is for `locale` to initialize each facet's `id` member the first time an instance of the facet is installed into a locale. This depends only on static storage being zero before constructors run (6.9.3.2).

30.3.1.3 Constructors and destructor

[locale.cons]

```
locale() noexcept;
```

Effects: Constructs a copy of the argument last passed to `locale::global(locale&)`, if it has been called; else, the resulting facets have virtual function semantics identical to those of `locale::classic()`.

NOTE This constructor yields a copy of the current global locale. It is commonly used as a default argument for function parameters of type `const locale&`.

```
explicit locale(const char* std_name);
```

Effects: Constructs a locale using standard C locale names, e.g., "POSIX". The resulting locale implements semantics defined to be associated with that name.

Throws: `runtime_error` if the argument is not valid, or is null.

Remarks: The set of valid string argument values is "C", "", and any implementation-defined values.

```
explicit locale(const string& std_name);
```

Effects: Equivalent to `locale(std_name.c_str())`.

```
locale(const locale& other, const char* std_name, category cats);
```

Preconditions: `cats` is a valid `category` value (30.3.1.2.1).

Effects: Constructs a locale as a copy of `other` except for the facets identified by the `category` argument, which instead implement the same semantics as `locale(std_name)`.

Throws: `runtime_error` if the second argument is not valid, or is null.

Remarks: The locale has a name if and only if `other` has a name.

```
locale(const locale& other, const string& std_name, category cats);
```

Effects: Equivalent to `locale(other, std_name.c_str(), cats)`.

```
template<class Facet> locale(const locale& other, Facet* f);
```

Effects: Constructs a locale incorporating all facets from the first argument except that of type `Facet`, and installs the second argument as the remaining facet. If `f` is null, the resulting object is a copy of `other`.

Remarks: If `f` is null, the resulting locale has the same name as `other`. Otherwise, the resulting locale has no name.

```
locale(const locale& other, const locale& one, category cats);
```

Preconditions: `cats` is a valid `category` value.

Effects: Constructs a locale incorporating all facets from the first argument except those that implement `cats`, which are instead incorporated from the second argument.

Remarks: If `cats` is equal to `locale::none`, the resulting locale has a name if and only if the first argument has a name. Otherwise, the resulting locale has a name if and only if the first two arguments both have names.

```
const locale& operator=(const locale& other) noexcept;
```

Effects: Creates a copy of `other`, replacing the current value.

Returns: `*this`.

30.3.1.4 Members

[`locale.members`]

```
template<class Facet> locale combine(const locale& other) const;
```

Effects: Constructs a locale incorporating all facets from `*this` except for that one facet of `other` that is identified by `Facet`.

Returns: The newly created locale.

Throws: `runtime_error` if `has_facet<Facet>(other)` is false.

Remarks: The resulting locale has no name.

```
string name() const;
```

Returns: The name of `*this`, if it has one; otherwise, the string `"*"`.

30.3.1.5 Operators

[`locale.operators`]

```
bool operator==(const locale& other) const;
```

Returns: `true` if both arguments are the same locale, or one is a copy of the other, or each has a name and the names are identical; `false` otherwise.

```
template<class charT, class traits, class Allocator>
bool operator()(const basic_string<charT, traits, Allocator>& s1,
                const basic_string<charT, traits, Allocator>& s2) const;
```

Effects: Compares two strings according to the `collate<charT>` facet.

Returns:

```
use_facet<collate<charT>>(*this).compare(s1.data(), s1.data() + s1.size(),
                                          s2.data(), s2.data() + s2.size()) < 0
```

Remarks: This member operator template (and therefore `locale` itself) meets the requirements for a comparator predicate template argument ([Clause 27](#)) applied to strings.

EXAMPLE A vector of strings `v` can be collated according to collation rules in locale `loc` simply by ([27.8.2](#), [24.3.11](#)):

```
std::sort(v.begin(), v.end(), loc);
```

30.3.1.6 Static members

[`locale.statics`]

```
static locale global(const locale& loc);
```

Effects: Sets the global locale to its argument. Causes future calls to the constructor `locale()` to return a copy of the argument. If the argument has a name, does

```
setlocale(LC_ALL, loc.name().c_str());
```

otherwise, the effect on the C locale, if any, is implementation-defined.

Returns: The previous value of `locale()`.

Remarks: No library function other than `locale::global()` affects the value returned by `locale()`.

NOTE See [30.5](#) for data race considerations when `setlocale` is invoked.

```
static const locale& classic();
```

The "C" locale.

Returns: A locale that implements the classic "C" locale semantics, equivalent to the value `locale("C")`.

Remarks: This locale, its facets, and their member functions, do not change with time.

30.3.2 locale globals

[locale.global.templates]

```
template<class Facet> const Facet& use_facet(const locale& loc);
```

Mandates: Facet is a facet class whose definition contains the public static member `id` as defined in 30.3.1.2.2.

Returns: A reference to the corresponding facet of `loc`, if present.

Throws: `bad_cast` if `has_facet<Facet>(loc)` is false.

Remarks: The reference returned remains valid at least as long as any copy of `loc` exists.

```
template<class Facet> bool has_facet(const locale& loc) noexcept;
```

Returns: `true` if the facet requested is present in `loc`; otherwise `false`.

30.3.3 Convenience interfaces

[locale.convenience]

30.3.3.1 Character classification

[classification]

```
template<class charT> bool isspace (charT c, const locale& loc);
template<class charT> bool isprint (charT c, const locale& loc);
template<class charT> bool iscntrl (charT c, const locale& loc);
template<class charT> bool isupper (charT c, const locale& loc);
template<class charT> bool islower (charT c, const locale& loc);
template<class charT> bool isalpha (charT c, const locale& loc);
template<class charT> bool isdigit (charT c, const locale& loc);
template<class charT> bool ispunct (charT c, const locale& loc);
template<class charT> bool isxdigit(charT c, const locale& loc);
template<class charT> bool isalnum (charT c, const locale& loc);
template<class charT> bool isgraph (charT c, const locale& loc);
template<class charT> bool isblank (charT c, const locale& loc);
```

Each of these functions `isF` returns the result of the expression:

```
use_facet<ctype<charT>>(loc).is(ctype_base::F, c)
```

where `F` is the `ctype_base::mask` value corresponding to that function (30.4.2).²⁴³

30.3.3.2 Character conversions

[conversions.character]

```
template<class charT> charT toupper(charT c, const locale& loc);
```

Returns: `use_facet<ctype<charT>>(loc).toupper(c)`.

```
template<class charT> charT tolower(charT c, const locale& loc);
```

Returns: `use_facet<ctype<charT>>(loc).tolower(c)`.

30.4 Standard locale categories

[locale.categories]

30.4.1 General

[locale.categories.general]

Each of the standard categories includes a family of facets. Some of these implement formatting or parsing of a datum, for use by standard or users' iostream operators `<<` and `>>`, as members `put()` and `get()`, respectively. Each such member function takes an `ios_base&` argument whose members `flags()`, `precision()`, and `width()`, specify the format of the corresponding datum (31.5.2). Those functions which need to use other facets call its member `getloc()` to retrieve the locale imbued there. Formatting facets use the character argument `fill` to fill out the specified width where necessary.

The `put()` members make no provision for error reporting. (Any failures of the `OutputIterator` argument can be extracted from the returned iterator.) The `get()` members take an `ios_base::iostate&` argument whose value they ignore, but set to `ios_base::failbit` in case of a parse error.

²⁴³) When used in a loop, it is faster to cache the `ctype<>` facet and use it directly, or use the vector form of `ctype<>::is`.

Within 30.4 it is unspecified whether one virtual function calls another virtual function.

30.4.2 The ctype category

[category.ctype]

30.4.2.1 General

[category.ctype.general]

```
namespace std {
    class ctype_base {
    public:
        using mask = see below;

        // numeric values are for exposition only.
        static const mask space = 1 << 0;
        static const mask print = 1 << 1;
        static const mask cntrl = 1 << 2;
        static const mask upper = 1 << 3;
        static const mask lower = 1 << 4;
        static const mask alpha = 1 << 5;
        static const mask digit = 1 << 6;
        static const mask punct = 1 << 7;
        static const mask xdigit = 1 << 8;
        static const mask blank = 1 << 9;
        static const mask alnum = alpha | digit;
        static const mask graph = alnum | punct;
    };
}
```

The type mask is a bitmask type (16.3.3.3.3).

30.4.2.2 Class template ctype

[locale.ctype]

30.4.2.2.1 General

[locale.ctype.general]

```
namespace std {
    template<class charT>
    class ctype : public locale::facet, public ctype_base {
    public:
        using char_type = charT;

        explicit ctype(size_t refs = 0);

        bool is(mask m, charT c) const;
        const charT* is(const charT* low, const charT* high, mask* vec) const;
        const charT* scan_is(mask m, const charT* low, const charT* high) const;
        const charT* scan_not(mask m, const charT* low, const charT* high) const;
        charT toupper(charT c) const;
        const charT* toupper(charT* low, const charT* high) const;
        charT tolower(charT c) const;
        const charT* tolower(charT* low, const charT* high) const;

        charT widen(char c) const;
        const char* widen(const char* low, const char* high, charT* to) const;
        char narrow(charT c, char dfault) const;
        const charT* narrow(const charT* low, const charT* high, char dfault, char* to) const;

        static locale::id id;

    protected:
        ~ctype();
        virtual bool do_is(mask m, charT c) const;
        virtual const charT* do_is(const charT* low, const charT* high, mask* vec) const;
        virtual const charT* do_scan_is(mask m, const charT* low, const charT* high) const;
        virtual const charT* do_scan_not(mask m, const charT* low, const charT* high) const;
        virtual charT do_toupper(charT) const;
        virtual const charT* do_toupper(charT* low, const charT* high) const;
        virtual charT do_tolower(charT) const;
        virtual const charT* do_tolower(charT* low, const charT* high) const;
    };
}
```

```

    virtual charT      do_widen(char) const;
    virtual const char* do_widen(const char* low, const char* high, charT* dest) const;
    virtual char       do_narrow(charT, char default) const;
    virtual const charT* do_narrow(const charT* low, const charT* high,
                                   char default, char* dest) const;
};
}

```

Class `ctype` encapsulates the C library `<cctype>` features. `istream` members are required to use `ctype<>` for character classing during input parsing.

The specializations required in Table 104 (30.3.1.2.1), namely `ctype<char>` and `ctype<wchar_t>`, implement character classing appropriate to the implementation's native character set.

30.4.2.2.2 `ctype` members

[`locale.ctype.members`]

```

bool      is(mask m, charT c) const;
const charT* is(const charT* low, const charT* high, mask* vec) const;

```

Returns: `do_is(m, c)` or `do_is(low, high, vec)`.

```

const charT* scan_is(mask m, const charT* low, const charT* high) const;

```

Returns: `do_scan_is(m, low, high)`.

```

const charT* scan_not(mask m, const charT* low, const charT* high) const;

```

Returns: `do_scan_not(m, low, high)`.

```

charT      toupper(charT c) const;
const charT* toupper(charT* low, const charT* high) const;

```

Returns: `do_toupper(c)` or `do_toupper(low, high)`.

```

charT      tolower(charT c) const;
const charT* tolower(charT* low, const charT* high) const;

```

Returns: `do_tolower(c)` or `do_tolower(low, high)`.

```

charT      widen(char c) const;
const char* widen(const char* low, const char* high, charT* to) const;

```

Returns: `do_widen(c)` or `do_widen(low, high, to)`.

```

char      narrow(charT c, char default) const;
const charT* narrow(const charT* low, const charT* high, char default, char* to) const;

```

Returns: `do_narrow(c, default)` or `do_narrow(low, high, default, to)`.

30.4.2.2.3 `ctype` virtual functions

[`locale.ctype.virtuals`]

```

bool      do_is(mask m, charT c) const;
const charT* do_is(const charT* low, const charT* high, mask* vec) const;

```

Effects: Classifies a character or sequence of characters. For each argument character, identifies a value `M` of type `ctype_base::mask`. The second form identifies a value `M` of type `ctype_base::mask` for each `*p` where `(low <= p && p < high)`, and places it into `vec[p - low]`.

Returns: The first form returns the result of the expression `(M & m) != 0`; i.e., `true` if the character has the characteristics specified. The second form returns `high`.

```

const charT* do_scan_is(mask m, const charT* low, const charT* high) const;

```

Effects: Locates a character in a buffer that conforms to a classification `m`.

Returns: The smallest pointer `p` in the range `[low, high)` such that `is(m, *p)` would return `true`; otherwise, returns `high`.

```

const charT* do_scan_not(mask m, const charT* low, const charT* high) const;

```

Effects: Locates a character in a buffer that fails to conform to a classification `m`.

Returns: The smallest pointer `p`, if any, in the range `[low, high)` such that `is(m, *p)` would return `false`; otherwise, returns `high`.

```
charT do_toupper(charT c) const;
const charT* do_toupper(charT* low, const charT* high) const;
```

Effects: Converts a character or characters to upper case. The second form replaces each character **p* in the range *[low,high)* for which a corresponding upper-case character exists, with that character.

Returns: The first form returns the corresponding upper-case character if it is known to exist, or its argument if not. The second form returns *high*.

```
charT do_tolower(charT c) const;
const charT* do_tolower(charT* low, const charT* high) const;
```

Effects: Converts a character or characters to lower case. The second form replaces each character **p* in the range *[low,high)* and for which a corresponding lower-case character exists, with that character.

Returns: The first form returns the corresponding lower-case character if it is known to exist, or its argument if not. The second form returns *high*.

```
charT do_widen(char c) const;
const char* do_widen(const char* low, const char* high, charT* dest) const;
```

Effects: Applies the simplest reasonable transformation from a *char* value or sequence of *char* values to the corresponding *charT* value or values.²⁴⁴ The only characters for which unique transformations are required are those in the basic character set (5.3).

For any named *ctype* category with a *ctype<charT>* facet *ctc* and valid *ctype_base::mask* value *M*, *(ctc.is(M, c) || !is(M, do_widen(c)))* is true.²⁴⁵

The second form transforms each character **p* in the range *[low,high)*, placing the result in *dest[p - low]*.

Returns: The first form returns the transformed value. The second form returns *high*.

```
char do_narrow(charT c, char dfault) const;
const charT* do_narrow(const charT* low, const charT* high, char dfault, char* dest) const;
```

Effects: Applies the simplest reasonable transformation from a *charT* value or sequence of *charT* values to the corresponding *char* value or values.

For any character *c* in the basic character set (5.3) the transformation is such that

```
do_widen(do_narrow(c, 0)) == c
```

For any named *ctype* category with a *ctype<char>* facet *ctc* however, and *ctype_base::mask* value *M*,

```
(is(M, c) || !ctc.is(M, do_narrow(c, dfault)))
```

is true (unless *do_narrow* returns *dfault*). In addition, for any digit character *c*, the expression *(do_narrow(c, dfault) - '0')* evaluates to the digit value of the character. The second form transforms each character **p* in the range *[low,high)*, placing the result (or *dfault* if no simple transformation is readily available) in *dest[p - low]*.

Returns: The first form returns the transformed value; or *dfault* if no mapping is readily available. The second form returns *high*.

30.4.2.3 Class template *ctype_byname*

[*locale.ctype.byname*]

```
namespace std {
    template<class charT>
        class ctype_byname : public ctype<charT> {
        public:
            using mask = typename ctype<charT>::mask;
            explicit ctype_byname(const char*, size_t refs = 0);
            explicit ctype_byname(const string&, size_t refs = 0);

        protected:
            ~ctype_byname();
```

244) The parameter *c* of *do_widen* is intended to accept values derived from *character-literals* for conversion to the locale's encoding.

245) In other words, the transformed character is not a member of any character classification that *c* is not also a member of.

```
};
}
```

30.4.2.4 ctype<char> specialization

[facet.ctype.special]

30.4.2.4.1 General

[facet.ctype.special.general]

```
namespace std {
    template<>
    class ctype<char> : public locale::facet, public ctype_base {
    public:
        using char_type = char;

        explicit ctype(const mask* tab = nullptr, bool del = false, size_t refs = 0);

        bool is(mask m, char c) const;
        const char* is(const char* low, const char* high, mask* vec) const;
        const char* scan_is (mask m, const char* low, const char* high) const;
        const char* scan_not(mask m, const char* low, const char* high) const;

        char toupper(char c) const;
        const char* toupper(char* low, const char* high) const;
        char tolower(char c) const;
        const char* tolower(char* low, const char* high) const;

        char widen(char c) const;
        const char* widen(const char* low, const char* high, char* to) const;
        char narrow(char c, char default) const;
        const char* narrow(const char* low, const char* high, char default, char* to) const;

        static locale::id id;
        static const size_t table_size = implementation-defined;

        const mask* table() const noexcept;
        static const mask* classic_table() noexcept;

    protected:
        ~ctype();
        virtual char do_toupper(char c) const;
        virtual const char* do_toupper(char* low, const char* high) const;
        virtual char do_tolower(char c) const;
        virtual const char* do_tolower(char* low, const char* high) const;

        virtual char do_widen(char c) const;
        virtual const char* do_widen(const char* low, const char* high, char* to) const;
        virtual char do_narrow(char c, char default) const;
        virtual const char* do_narrow(const char* low, const char* high,
                                     char default, char* to) const;
    };
}
```

A specialization `ctype<char>` is provided so that the member functions on type `char` can be implemented inline.²⁴⁶ The implementation-defined value of member `table_size` is at least 256.

30.4.2.4.2 Destructor

[facet.ctype.char.dtor]

```
~ctype();
```

Effects: If the constructor's first argument was nonzero, and its second argument was `true`, does `delete [] table()`.

²⁴⁶ Only the `char` (not `unsigned char` and `signed char`) form is provided. The specialization is specified in the standard, and not left as an implementation detail, because it affects the derivation interface for `ctype<char>`.

30.4.2.4.3 Members

[facet.ctype.char.members]

In the following member descriptions, for `unsigned char` values `v` where `v >= table_size`, `table()[v]` is assumed to have an implementation-specific value (possibly different for each such value `v`) without performing the array lookup.

```
explicit ctype(const mask* tbl = nullptr, bool del = false, size_t refs = 0);
```

Preconditions: Either `tbl == nullptr` is true or `[tbl, tbl+table_size)` is a valid range.

Effects: Passes its `refs` argument to its base class constructor.

```
bool is(mask m, char c) const;
const char* is(const char* low, const char* high, mask* vec) const;
```

Effects: The second form, for all `*p` in the range `[low, high)`, assigns into `vec[p - low]` the value `table()[ (unsigned char)*p ]`.

Returns: The first form returns `table()[ (unsigned char)c ] & m`; the second form returns `high`.

```
const char* scan_is(mask m, const char* low, const char* high) const;
```

Returns: The smallest `p` in the range `[low, high)` such that

```
table()[ (unsigned char) *p ] & m
is true.
```

```
const char* scan_not(mask m, const char* low, const char* high) const;
```

Returns: The smallest `p` in the range `[low, high)` such that

```
table()[ (unsigned char) *p ] & m
is false.
```

```
char toupper(char c) const;
const char* toupper(char* low, const char* high) const;
```

Returns: `do_toupper(c)` or `do_toupper(low, high)`, respectively.

```
char tolower(char c) const;
const char* tolower(char* low, const char* high) const;
```

Returns: `do_tolower(c)` or `do_tolower(low, high)`, respectively.

```
char widen(char c) const;
const char* widen(const char* low, const char* high, char* to) const;
```

Returns: `do_widen(c)` or `do_widen(low, high, to)`, respectively.

```
char narrow(char c, char dfaul) const;
const char* narrow(const char* low, const char* high, char dfaul, char* to) const;
```

Returns: `do_narrow(c, dfaul)` or `do_narrow(low, high, dfaul, to)`, respectively.

```
const mask* table() const noexcept;
```

Returns: The first constructor argument, if it was nonzero, otherwise `classic_table()`.

30.4.2.4.4 Static members

[facet.ctype.char.statics]

```
static const mask* classic_table() noexcept;
```

Returns: A pointer to the initial element of an array of size `table_size` which represents the classifications of characters in the "C" locale.

30.4.2.4.5 Virtual functions

[facet.ctype.char.virtuals]

```
char do_toupper(char) const;
const char* do_toupper(char* low, const char* high) const;
char do_tolower(char) const;
const char* do_tolower(char* low, const char* high) const;
```

```

virtual char      do_widen(char c) const;
virtual const char* do_widen(const char* low, const char* high, char* to) const;
virtual char      do_narrow(char c, char dfault) const;
virtual const char* do_narrow(const char* low, const char* high,
                             char dfault, char* to) const;

```

These functions are described identically as those members of the same name in the `ctype` class template (30.4.2.2.2).

30.4.2.5 Class template `codecvt`

[locale.codecvt]

30.4.2.5.1 General

[locale.codecvt.general]

```

namespace std {
    class codecvt_base {
    public:
        enum result { ok, partial, error, noconv };
    };

    template<class internT, class externT, class stateT>
    class codecvt : public locale::facet, public codecvt_base {
    public:
        using intern_type = internT;
        using extern_type = externT;
        using state_type = stateT;

        explicit codecvt(size_t refs = 0);

        result out(
            stateT& state,
            const internT* from, const internT* from_end, const internT*& from_next,
            externT* to,        externT* to_end,        externT*& to_next) const;

        result unshift(
            stateT& state,
            externT* to,        externT* to_end,        externT*& to_next) const;

        result in(
            stateT& state,
            const externT* from, const externT* from_end, const externT*& from_next,
            internT* to,        internT* to_end,        internT*& to_next) const;

        int encoding() const noexcept;
        bool always_noconv() const noexcept;
        int length(stateT&, const externT* from, const externT* end, size_t max) const;
        int max_length() const noexcept;

        static locale::id id;

    protected:
        ~codecvt();
        virtual result do_out(
            stateT& state,
            const internT* from, const internT* from_end, const internT*& from_next,
            externT* to,        externT* to_end,        externT*& to_next) const;
        virtual result do_in(
            stateT& state,
            const externT* from, const externT* from_end, const externT*& from_next,
            internT* to,        internT* to_end,        internT*& to_next) const;
        virtual result do_unshift(
            stateT& state,
            externT* to,        externT* to_end,        externT*& to_next) const;

        virtual int do_encoding() const noexcept;
        virtual bool do_always_noconv() const noexcept;
        virtual int do_length(stateT&, const externT* from, const externT* end, size_t max) const;

```

```

        virtual int do_max_length() const noexcept;
    };
}

```

The class `codecvt<internT, externT, stateT>` is for use when converting from one character encoding to another, such as from wide characters to multibyte characters or between wide character encodings such as UTF-32 and EUC.

The `stateT` argument selects the pair of character encodings being mapped between.

The specializations required in Table 104 (30.3.1.2.1) convert the implementation-defined native character set. `codecvt<char, char, mbstate_t>` implements a degenerate conversion; it does not convert at all. The specialization `codecvt<char16_t, char8_t, mbstate_t>` converts between the UTF-16 and UTF-8 encoding forms, and the specialization `codecvt<char32_t, char8_t, mbstate_t>` converts between the UTF-32 and UTF-8 encoding forms. `codecvt<wchar_t, char, mbstate_t>` converts between the native character sets for ordinary and wide characters. Specializations on `mbstate_t` perform conversion between encodings known to the library implementer. Other encodings can be converted by specializing on a program-defined `stateT` type. Objects of type `stateT` can contain any state that is useful to communicate to or from the specialized `do_in` or `do_out` members.

30.4.2.5.2 Members

[locale.codecvt.members]

```

result out(
    stateT& state,
    const internT* from, const internT* from_end, const internT*& from_next,
    externT* to, externT* to_end, externT*& to_next) const;

    Returns: do_out(state, from, from_end, from_next, to, to_end, to_next).

result unshift(stateT& state, externT* to, externT* to_end, externT*& to_next) const;

    Returns: do_unshift(state, to, to_end, to_next).

result in(
    stateT& state,
    const externT* from, const externT* from_end, const externT*& from_next,
    internT* to, internT* to_end, internT*& to_next) const;

    Returns: do_in(state, from, from_end, from_next, to, to_end, to_next).

int encoding() const noexcept;

    Returns: do_encoding().

bool always_noconv() const noexcept;

    Returns: do_always_noconv().

int length(stateT& state, const externT* from, const externT* from_end, size_t max) const;

    Returns: do_length(state, from, from_end, max).

int max_length() const noexcept;

    Returns: do_max_length().

```

30.4.2.5.3 Virtual functions

[locale.codecvt.virtuals]

```

result do_out(
    stateT& state,
    const internT* from, const internT* from_end, const internT*& from_next,
    externT* to, externT* to_end, externT*& to_next) const;

result do_in(
    stateT& state,
    const externT* from, const externT* from_end, const externT*& from_next,
    internT* to, internT* to_end, internT*& to_next) const;

    Preconditions: (from <= from_end && to <= to_end) is well-defined and true; state is initialized,
    if at the beginning of a sequence, or else is equal to the result of converting the preceding characters in
    the sequence.

```

Effects: Translates characters in the source range `[from, from_end)`, placing the results in sequential positions starting at destination `to`. Converts no more than `(from_end - from)` source elements, and stores no more than `(to_end - to)` destination elements.

Stops if it encounters a character it cannot convert. It always leaves the `from_next` and `to_next` pointers pointing one beyond the last element successfully converted. If returns `noconv`, `internT` and `externT` are the same type and the converted sequence is identical to the input sequence `[from, from_next)`. `to_next` is set equal to `to`, the value of `state` is unchanged, and there are no changes to the values in `[to, to_end)`.

A `codecvt` facet that is used by `basic_filebuf` (31.10) shall have the property that if

```
do_out(state, from, from_end, from_next, to, to_end, to_next)
```

would return `ok`, where `from != from_end`, then

```
do_out(state, from, from + 1, from_next, to, to_end, to_next)
```

shall also return `ok`, and that if

```
do_in(state, from, from_end, from_next, to, to_end, to_next)
```

would return `ok`, where `to != to_end`, then

```
do_in(state, from, from_end, from_next, to, to + 1, to_next)
```

shall also return `ok`.²⁴⁷

NOTE 1 As a result of operations on `state`, it can return `ok` or `partial` and set `from_next == from` and `to_next != to`.

Returns: An enumeration value, as summarized in Table 106.

Table 106 — `do_in/do_out` result values [tab:locale.codecvt.inout]

Value	Meaning
<code>ok</code>	completed the conversion
<code>partial</code>	not all source characters converted
<code>error</code>	encountered a character in <code>[from, from_end)</code> that cannot be converted
<code>noconv</code>	<code>internT</code> and <code>externT</code> are the same type, and input sequence is identical to converted sequence

A return value of `partial`, if `(from_next == from_end)`, indicates that either the destination sequence has not absorbed all the available destination elements, or that additional source elements are needed before another destination element can be produced.

Remarks: Its operations on `state` are unspecified.

NOTE 2 This argument can be used, for example, to maintain shift state, to specify conversion options (such as count only), or to identify a cache of seek offsets.

```
result do_unshift(stateT& state, externT* to, externT* to_end, externT*& to_next) const;
```

Preconditions: `(to <= to_end)` is well-defined and `true`; `state` is initialized, if at the beginning of a sequence, or else is equal to the result of converting the preceding characters in the sequence.

Effects: Places characters starting at `to` that should be appended to terminate a sequence when the current `stateT` is given by `state`.²⁴⁸ Stores no more than `(to_end - to)` destination elements, and leaves the `to_next` pointer pointing one beyond the last element successfully stored.

Returns: An enumeration value, as summarized in Table 107.

247) Informally, this means that `basic_filebuf` assumes that the mappings from internal to external characters is 1 to N: that a `codecvt` facet that is used by `basic_filebuf` can translate characters one internal character at a time.

248) Typically these will be characters to return the state to `stateT()`.

Table 107 — `do_unshift` result values [tab:locale.codecvt.unshift]

Value	Meaning
<code>ok</code>	completed the sequence
<code>partial</code>	space for more than <code>to_end - to</code> destination elements was needed to terminate a sequence given the value of <code>state</code>
<code>error</code>	an unspecified error has occurred
<code>noconv</code>	no termination is needed for this <code>state_type</code>

```
int do_encoding() const noexcept;
```

Returns: -1 if the encoding of the `externT` sequence is state-dependent; else the constant number of `externT` characters needed to produce an internal character; or 0 if this number is not a constant.²⁴⁹

```
bool do_always_noconv() const noexcept;
```

Returns: true if `do_in()` and `do_out()` return `noconv` for all valid argument values. `codecvt<char, char, mbstate_t>` returns true.

```
int do_length(stateT& state, const externT* from, const externT* from_end, size_t max) const;
```

Preconditions: (`from <= from_end`) is well-defined and true; `state` is initialized, if at the beginning of a sequence, or else is equal to the result of converting the preceding characters in the sequence.

Effects: The effect on the `state` argument is as if it called `do_in(state, from, from_end, from, to, to+max, to)` for `to` pointing to a buffer of at least `max` elements.

Returns: (`from_next-from`) where `from_next` is the largest value in the range `[from, from_end]` such that the sequence of values in the range `[from, from_next)` represents `max` or fewer valid complete characters of type `internT`. The specialization `codecvt<char, char, mbstate_t>`, returns the lesser of `max` and (`from_end-from`).

```
int do_max_length() const noexcept;
```

Returns: The maximum value that `do_length(state, from, from_end, 1)` can return for any valid range `[from, from_end)` and `stateT` value `state`. The specialization `codecvt<char, char, mbstate_t>::do_max_length()` returns 1.

30.4.2.6 Class template `codecvt_byname`

[locale.codecvt.byname]

```
namespace std {
    template<class internT, class externT, class stateT>
        class codecvt_byname : public codecvt<internT, externT, stateT> {
        public:
            explicit codecvt_byname(const char*, size_t refs = 0);
            explicit codecvt_byname(const string&, size_t refs = 0);

        protected:
            ~codecvt_byname();
        };
}
```

30.4.3 The numeric category

[category.numeric]

30.4.3.1 General

[category.numeric.general]

The classes `num_get<>` and `num_put<>` handle numeric formatting and parsing. Virtual functions are provided for several numeric types. Implementations may (but are not required to) delegate extraction of smaller types to extractors for larger types.²⁵⁰

249) If `encoding()` yields -1, then more than `max_length()` `externT` elements can be consumed when producing a single `internT` character, and additional `externT` elements can appear at the end of a sequence after those that yield the final `internT` character.

250) Parsing "-1" correctly into, e.g., an `unsigned short` requires that the corresponding member `get()` at least extract the sign before delegating.

All specifications of member functions for `num_put` and `num_get` in the subclauses of 30.4.3 only apply to the specializations required in Tables 104 and 105 (30.3.1.2.1), namely `num_get<char>`, `num_get<wchar_t>`, `num_get<C, InputIterator>`, `num_put<char>`, `num_put<wchar_t>`, and `num_put<C, OutputIterator>`. These specializations refer to the `ios_base&` argument for formatting specifications (30.4), and to its imbued locale for the `num_punct<>` facet to identify all numeric punctuation preferences, and also for the `ctype<>` facet to perform character classification.

Extractor and inserter members of the standard iostreams use `num_get<>` and `num_put<>` member functions for formatting and parsing numeric values (31.7.5.3.1, 31.7.6.3.1).

30.4.3.2 Class template `num_get`

[locale.num.get]

30.4.3.2.1 General

[locale.num.get.general]

```
namespace std {
    template<class charT, class InputIterator = istreambuf_iterator<charT>>
        class num_get : public locale::facet {
        public:
            using char_type = charT;
            using iter_type = InputIterator;

            explicit num_get(size_t refs = 0);

            iter_type get(iter_type in, iter_type end, ios_base&,
                          ios_base::iostate& err, bool& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&,
                          ios_base::iostate& err, long& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&,
                          ios_base::iostate& err, long long& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&,
                          ios_base::iostate& err, unsigned short& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&,
                          ios_base::iostate& err, unsigned int& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&,
                          ios_base::iostate& err, unsigned long& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&,
                          ios_base::iostate& err, unsigned long long& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&,
                          ios_base::iostate& err, float& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&,
                          ios_base::iostate& err, double& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&,
                          ios_base::iostate& err, long double& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&,
                          ios_base::iostate& err, void*& v) const;

            static locale::id id;

        protected:
            ~num_get();
            virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                    ios_base::iostate& err, bool& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                    ios_base::iostate& err, long& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                    ios_base::iostate& err, long long& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                    ios_base::iostate& err, unsigned short& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                    ios_base::iostate& err, unsigned int& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                    ios_base::iostate& err, unsigned long& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                    ios_base::iostate& err, unsigned long long& v) const;
        };
}
```

```

    virtual iter_type do_get(iter_type, iter_type, ios_base&,
                            ios_base::iostate& err, float& v) const;
    virtual iter_type do_get(iter_type, iter_type, ios_base&,
                            ios_base::iostate& err, double& v) const;
    virtual iter_type do_get(iter_type, iter_type, ios_base&,
                            ios_base::iostate& err, long double& v) const;
    virtual iter_type do_get(iter_type, iter_type, ios_base&,
                            ios_base::iostate& err, void*& v) const;
};
}

```

The facet `num_get` is used to parse numeric values from an input sequence such as an istream.

30.4.3.2.2 Members

[facet.num.get.members]

```

iter_type get(iter_type in, iter_type end, ios_base& str,
              ios_base::iostate& err, bool& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
              ios_base::iostate& err, long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
              ios_base::iostate& err, long long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
              ios_base::iostate& err, unsigned short& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
              ios_base::iostate& err, unsigned int& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
              ios_base::iostate& err, unsigned long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
              ios_base::iostate& err, unsigned long long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
              ios_base::iostate& err, float& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
              ios_base::iostate& err, double& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
              ios_base::iostate& err, long double& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
              ios_base::iostate& err, void*& val) const;

```

Returns: `do_get(in, end, str, err, val)`.

30.4.3.2.3 Virtual functions

[facet.num.get.virtuals]

```

iter_type do_get(iter_type in, iter_type end, ios_base& str,
                 ios_base::iostate& err, long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
                 ios_base::iostate& err, long long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
                 ios_base::iostate& err, unsigned short& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
                 ios_base::iostate& err, unsigned int& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
                 ios_base::iostate& err, unsigned long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
                 ios_base::iostate& err, unsigned long long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
                 ios_base::iostate& err, float& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
                 ios_base::iostate& err, double& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
                 ios_base::iostate& err, long double& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
                 ios_base::iostate& err, void*& val) const;

```

Effects: Reads characters from `in`, interpreting them according to `str.flags()`, `use_facet<ctype<charT>>(loc)`, and `use_facet<numeric<charT>>(loc)`, where `loc` is `str.getloc()`.

The details of this operation occur in three stages:

- Stage 1: Determine a conversion specifier.
- Stage 2: Extract characters from `in` and determine a corresponding `char` value for the format expected by the conversion specification determined in stage 1.
- Stage 3: Store results.

The details of the stages are presented below.

Stage 1: The function initializes local variables via

```
fmtflags flags = str.flags();
fmtflags basefield = (flags & ios_base::basefield);
fmtflags uppercase = (flags & ios_base::uppercase);
fmtflags boolalpha = (flags & ios_base::boolalpha);
```

For conversion to an integral type, the function determines the integral conversion specifier as indicated in Table 108. The table is ordered. That is, the first line whose condition is true applies.

Table 108 — Integer conversions [tab:facet.num.get.int]

State	stdio equivalent
<code>basefield == oct</code>	<code>%o</code>
<code>basefield == hex</code>	<code>%X</code>
<code>basefield == 0</code>	<code>%i</code>
signed integral type	<code>%d</code>
unsigned integral type	<code>%u</code>

For conversions to a floating-point type the specifier is `%g`.

For conversions to `void*` the specifier is `%p`.

A length modifier is added to the conversion specification, if needed, as indicated in Table 109.

Table 109 — Length modifier [tab:facet.num.get.length]

Type	Length modifier
<code>short</code>	<code>h</code>
<code>unsigned short</code>	<code>h</code>
<code>long</code>	<code>l</code>
<code>unsigned long</code>	<code>l</code>
<code>long long</code>	<code>ll</code>
<code>unsigned long long</code>	<code>ll</code>
<code>double</code>	<code>l</code>
<code>long double</code>	<code>L</code>

Stage 2: If `in == end` then stage 2 terminates. Otherwise a `charT` is taken from `in` and local variables are initialized as if by

```
char_type ct = *in;
char c = src[find(atoms, atoms + sizeof(src) - 1, ct) - atoms];
if (ct == use_facet<num_punct<charT>>(loc).decimal_point())
    c = '.';
bool discard =
    ct == use_facet<num_punct<charT>>(loc).thousands_sep()
    && use_facet<num_punct<charT>>(loc).grouping().length() != 0;
```

where the values `src` and `atoms` are defined as if by:

```
static const char src[] = "0123456789abcdefghijklmnopqrstuvwxyz+-";
char_type atoms[sizeof(src)];
use_facet<ctype<charT>>(loc).widen(src, src + sizeof(src), atoms);
```

for this value of `loc`.

If `discard` is `true`, then if `'.'` has not yet been accumulated, then the position of the character is remembered, but the character is otherwise ignored. Otherwise, if `'.'` has already been accumulated, the character is discarded and Stage 2 terminates. If it is not discarded, then a

check is made to determine if `c` is allowed as the next character of an input field of the conversion specifier returned by Stage 1. If so, it is accumulated.

If the character is either discarded or accumulated then `in` is advanced by `++in` and processing returns to the beginning of stage 2.

EXAMPLE 1 Given an input sequence of `"0x1a.bp+07p"`,

- if the conversion specifier returned by Stage 1 is `%d`, `"0"` is accumulated;
- if the conversion specifier returned by Stage 1 is `%i`, `"0x1a"` are accumulated;
- if the conversion specifier returned by Stage 1 is `%g`, `"0x1a.bp+07"` are accumulated.

In all cases, the remainder is left in the input.

Stage 3: The sequence of `chars` accumulated in stage 2 (the field) is converted to a numeric value by the rules of one of the functions declared in the header `<cstdlib>`:

- For a signed integer value, the function `strtoll`.
- For an unsigned integer value, the function `strtoull`.
- For a float value, the function `strtof`.
- For a double value, the function `strtod`.
- For a long double value, the function `strtold`.

The numeric value to be stored can be one of:

- zero, if the conversion function does not convert the entire field.
- the most positive (or negative) representable value, if the field to be converted to a signed integer type represents a value too large positive (or negative) to be represented in `val`.
- the most positive representable value, if the field to be converted to an unsigned integer type represents a value that cannot be represented in `val`.
- the converted value, otherwise.

The resultant numeric value is stored in `val`. If the conversion function does not convert the entire field, or if the field represents a value outside the range of representable values, `ios_base::failbit` is assigned to `err`.

Digit grouping is checked. That is, the positions of discarded separators are examined for consistency with `use_facet<num_punct<charT>>(loc).grouping()`. If they are not consistent then `ios_base::failbit` is assigned to `err`.

In any case, if stage 2 processing was terminated by the test for `in == end` then `err |= ios_base::eofbit` is performed.

```
iter_type do_get(iter_type in, iter_type end, ios_base& str,
                ios_base::iostate& err, bool& val) const;
```

Effects: If `(str.flags() & ios_base::boolalpha) == 0` then input proceeds as it would for a long except that if a value is being stored into `val`, the value is determined according to the following: If the value to be stored is 0 then `false` is stored. If the value is 1 then `true` is stored. Otherwise `true` is stored and `ios_base::failbit` is assigned to `err`.

Otherwise target sequences are determined “as if” by calling the members `false_name()` and `true_name()` of the facet obtained by `use_facet<num_punct<charT>>(str.getloc())`. Successive characters in the range `[in, end)` (see 24.2.4) are obtained and matched against corresponding positions in the target sequences only as necessary to identify a unique match. The input iterator `in` is compared to `end` only when necessary to obtain a character. If a target sequence is uniquely matched, `val` is set to the corresponding value. Otherwise `false` is stored and `ios_base::failbit` is assigned to `err`.

The `in` iterator is always left pointing one position beyond the last character successfully matched. If `val` is set, then `err` is set to `str.goodbit`; or to `str.eofbit` if, when seeking another character to match, it is found that `(in == end)`. If `val` is not set, then `err` is set to `str.failbit`; or to `(str.failbit | str.eofbit)` if the reason for the failure was that `(in == end)`.

EXAMPLE 2 For targets `true: "a"` and `false: "abb"`, the input sequence `"a"` yields `val == true` and `err == str.eofbit`; the input sequence `"abc"` yields `err = str.failbit`, with `in` ending at the `'c'` element. For targets `true: "1"` and `false: "0"`, the input sequence `"1"` yields `val == true` and `err == str.goodbit`. For empty targets `( "")`, any input sequence yields `err == str.failbit`.

Returns: `in`.

30.4.3.3 Class template num_put

[locale.num.put]

30.4.3.3.1 General

[locale.num.put.general]

```

namespace std {
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
        class num_put : public locale::facet {
        public:
            using char_type = charT;
            using iter_type = OutputIterator;

            explicit num_put(size_t refs = 0);

            iter_type put(iter_type s, ios_base& f, char_type fill, bool v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, long long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, unsigned long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, unsigned long long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, double v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, long double v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, const void* v) const;

            static locale::id id;

        protected:
            ~num_put();
            virtual iter_type do_put(iter_type, ios_base&, char_type fill, bool v) const;
            virtual iter_type do_put(iter_type, ios_base&, char_type fill, long v) const;
            virtual iter_type do_put(iter_type, ios_base&, char_type fill, long long v) const;
            virtual iter_type do_put(iter_type, ios_base&, char_type fill, unsigned long) const;
            virtual iter_type do_put(iter_type, ios_base&, char_type fill, unsigned long long) const;
            virtual iter_type do_put(iter_type, ios_base&, char_type fill, double v) const;
            virtual iter_type do_put(iter_type, ios_base&, char_type fill, long double v) const;
            virtual iter_type do_put(iter_type, ios_base&, char_type fill, const void* v) const;
        };
    }

```

The facet `num_put` is used to format numeric values to a character sequence such as an ostream.

30.4.3.3.2 Members

[facet.num.put.members]

```

iter_type put(iter_type out, ios_base& str, char_type fill, bool val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, unsigned long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, unsigned long long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, double val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long double val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, const void* val) const;

```

Returns: `do_put(out, str, fill, val)`.

30.4.3.3.3 Virtual functions

[facet.num.put.virtuals]

```

iter_type do_put(iter_type out, ios_base& str, char_type fill, long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, long long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, double val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, long double val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, const void* val) const;

```

Effects: Writes characters to the sequence `out`, formatting `val` as desired. In the following description, `loc` names a local variable initialized as

```
locale loc = str.getloc();
```

The details of this operation occur in several stages:

- Stage 1: Determine a printf conversion specifier **spec** and determine the characters that would be printed by **printf** (31.13) given this conversion specifier for

```
printf(spec, val)
```

assuming that the current locale is the "C" locale.
- Stage 2: Adjust the representation by converting each **char** determined by stage 1 to a **charT** using a conversion and values returned by members of **use_facet<num_punct<charT>>(loc)**.
- Stage 3: Determine where padding is required.
- Stage 4: Insert the sequence into the **out**.

Detailed descriptions of each stage follow.

Returns: **out**.

Stage 1: The first action of stage 1 is to determine a conversion specifier. The tables that describe this determination use the following local variables

```
fmtflags flags = str.flags();
fmtflags basefield = (flags & (ios_base::basefield));
fmtflags uppercase = (flags & (ios_base::uppercase));
fmtflags floatfield = (flags & (ios_base::floatfield));
fmtflags showpos = (flags & (ios_base::showpos));
fmtflags showbase = (flags & (ios_base::showbase));
fmtflags showpoint = (flags & (ios_base::showpoint));
```

All tables used in describing stage 1 are ordered. That is, the first line whose condition is true applies. A line without a condition is the default behavior when none of the earlier lines apply.

For conversion from an integral type other than a character type, the function determines the integral conversion specifier as indicated in Table 110.

Table 110 — Integer conversions [tab:facet.num.put.int]

State	stdio equivalent
<code>basefield == ios_base::oct</code>	<code>%o</code>
<code>(basefield == ios_base::hex) && !uppercase</code>	<code>%x</code>
<code>(basefield == ios_base::hex)</code>	<code>%X</code>
for a signed integral type	<code>%d</code>
for an unsigned integral type	<code>%u</code>

For conversion from a floating-point type, the function determines the floating-point conversion specifier as indicated in Table 111.

Table 111 — Floating-point conversions [tab:facet.num.put.fp]

State	stdio equivalent
<code>floatfield == ios_base::fixed</code>	<code>%f</code>
<code>floatfield == ios_base::scientific && !uppercase</code>	<code>%e</code>
<code>floatfield == ios_base::scientific</code>	<code>%E</code>
<code>floatfield == (ios_base::fixed ios_base::scientific) && !uppercase</code>	<code>%a</code>
<code>floatfield == (ios_base::fixed ios_base::scientific)</code>	<code>%A</code>
<code>!uppercase</code>	<code>%g</code>
<code>otherwise</code>	<code>%G</code>

For conversions from an integral or floating-point type a length modifier is added to the conversion specifier as indicated in Table 112.

The conversion specifier has the following optional additional qualifiers prepended as indicated in Table 113.

For conversion from a floating-point type, if `floatfield != (ios_base::fixed | ios_base::scientific)`, `str.precision()` is specified as precision in the conversion specification. Otherwise, no precision is specified.

Table 112 — Length modifier [tab:facet.num.put.length]

Type	Length modifier
long	l
long long	ll
unsigned long	l
unsigned long long	ll
long double	L
<i>otherwise</i>	<i>none</i>

Table 113 — Numeric conversions [tab:facet.num.put.conv]

Type(s)	State	stdio equivalent
an integral type	showpos	+
	showbase	#
a floating-point type	showpos	+
	showpoint	#

For conversion from `void*` the specifier is `%p`.

The representations at the end of stage 1 consists of the `char`'s that would be printed by a call of `printf(s, val)` where `s` is the conversion specifier determined above.

Stage 2: Any character `c` other than a decimal point(`.`) is converted to a `charT` via

```
use_facet<ctype<charT>>(loc).widen(c)
```

A local variable `punct` is initialized via

```
const numpunct<charT>& punct = use_facet<numpunct<charT>>(loc);
```

For arithmetic types, `punct.thousands_sep()` characters are inserted into the sequence as determined by the value returned by `punct.do_grouping()` using the method described in 30.4.4.1.3.

Decimal point characters(`.`) are replaced by `punct.decimal_point()`.

Stage 3: A local variable is initialized as

```
fmtflags adjustfield = (flags & (ios_base::adjustfield));
```

The location of any padding²⁵¹ is determined according to Table 114.

Table 114 — Fill padding [tab:facet.num.put.fill]

State	Location
<code>adjustfield == ios_base::left</code>	pad after
<code>adjustfield == ios_base::right</code>	pad before
<code>adjustfield == internal</code> and a sign occurs in the representation	pad after the sign
<code>adjustfield == internal</code> and representation after stage 1 began with <code>0x</code> or <code>0X</code>	pad after <code>x</code> or <code>X</code>
<i>otherwise</i>	pad before

If `str.width()` is nonzero and the number of `charT`'s in the sequence after stage 2 is less than `str.width()`, then enough fill characters are added to the sequence at the position indicated for padding to bring the length of the sequence to `str.width()`.

`str.width(0)` is called.

Stage 4: The sequence of `charT`'s at the end of stage 3 are output via

```
*out++ = c
```

²⁵¹) The conversion specification `#0` generates a leading 0 which is *not* a padding character.

```
iter_type do_put(iter_type out, ios_base& str, char_type fill, bool val) const;
```

Returns: If `(str.flags() & ios_base::boolalpha) == 0` returns `do_put(out, str, fill, (int)val)`, otherwise obtains a string `s` as if by

```
string_type s =
    val ? use_facet<num_punct<charT>>(loc).truename()
        : use_facet<num_punct<charT>>(loc).falsename();
```

and then inserts each character `c` of `s` into `out` via `*out++ = c` and returns `out`.

30.4.4 The numeric punctuation facet

[facet.num_punct]

30.4.4.1 Class template num_punct

[locale.num_punct]

30.4.4.1.1 General

[locale.num_punct.general]

```
namespace std {
    template<class charT>
    class num_punct : public locale::facet {
    public:
        using char_type = charT;
        using string_type = basic_string<charT>;

        explicit num_punct(size_t refs = 0);

        char_type decimal_point() const;
        char_type thousands_sep() const;
        string grouping() const;
        string_type truename() const;
        string_type falsename() const;

        static locale::id id;

    protected:
        ~num_punct(); // virtual
        virtual char_type do_decimal_point() const;
        virtual char_type do_thousands_sep() const;
        virtual string do_grouping() const;
        virtual string_type do_truename() const; // for bool
        virtual string_type do_falsename() const; // for bool
    };
}
```

`num_punct<>` specifies numeric punctuation. The specializations required in Table 104 (30.3.1.2.1), namely `num_punct<wchar_t>` and `num_punct<char>`, provide classic "C" numeric formats, i.e., they contain information equivalent to that contained in the "C" locale or their wide character counterparts as if obtained by a call to `widen`.

The syntax for number formats is as follows, where *digit* represents the radix set specified by the `fmtflags` argument value, and *thousands-sep* and *decimal-point* are the results of corresponding `num_punct<charT>` members. Integer values have the format:

```
intval:
    sign_opt units
sign:
    +
    -
units:
    digits
    digits thousands-sep units
digits:
    digit digits_opt
```

and floating-point values have:

```
floatval:
    sign_opt units fractional_opt exponent_opt
    sign_opt decimal-point digits exponent_opt
```

```
fractional:
    decimal-point digitsopt
exponent:
    e signopt digits
e:
    e
    E
```

where the number of digits between *thousands-seps* is as specified by `do_grouping()`. For parsing, if the *digits* portion contains no thousands-separators, no grouping constraint is applied.

30.4.4.1.2 Members

[facet.numpunct.members]

```
char_type decimal_point() const;
```

Returns: `do_decimal_point()`.

```
char_type thousands_sep() const;
```

Returns: `do_thousands_sep()`.

```
string grouping() const;
```

Returns: `do_grouping()`.

```
string_type truename() const;
```

```
string_type falsename() const;
```

Returns: `do_truename()` or `do_falsename()`, respectively.

30.4.4.1.3 Virtual functions

[facet.numpunct.virtuals]

```
char_type do_decimal_point() const;
```

Returns: A character for use as the decimal radix separator. The required specializations return `'.'` or `L'.'`.

```
char_type do_thousands_sep() const;
```

Returns: A character for use as the digit group separator. The required specializations return `','` or `L','`.

```
string do_grouping() const;
```

Returns: A string `vec` used as a vector of integer values, in which each element `vec[i]` represents the number of digits²⁵² in the group at position `i`, starting with position 0 as the rightmost group. If `vec.size() <= i`, the number is the same as group `(i - 1)`; if `(i < 0 || vec[i] <= 0 || vec[i] == CHAR_MAX)`, the size of the digit group is unlimited.

The required specializations return the empty string, indicating no grouping.

```
string_type do_truename() const;
```

```
string_type do_falsename() const;
```

Returns: A string representing the name of the boolean value `true` or `false`, respectively.

In the base class implementation these names are `"true"` and `"false"`, or `L"true"` and `L"false"`.

30.4.4.2 Class template `numpunct_byname`

[locale.numpunct.byname]

```
namespace std {
    template<class charT>
        class numpunct_byname : public numpunct<charT> {
            // this class is specialized for char and wchar_t.
        public:
            using char_type = charT;
            using string_type = basic_string<charT>;
```

²⁵² Thus, the string `"\003"` specifies groups of 3 digits each, and `"3"` probably indicates groups of 51 (!) digits each, because 51 is the ASCII value of `"3"`.

```

explicit numpunct_byname(const char*, size_t refs = 0);
explicit numpunct_byname(const string&, size_t refs = 0);

protected:
    ~numpunct_byname();
};
}

```

30.4.5 The collate category

[category.collate]

30.4.5.1 Class template collate

[locale.collate]

30.4.5.1.1 General

[locale.collate.general]

```

namespace std {
    template<class charT>
        class collate : public locale::facet {
        public:
            using char_type    = charT;
            using string_type = basic_string<charT>;

            explicit collate(size_t refs = 0);

            int compare(const charT* low1, const charT* high1,
                       const charT* low2, const charT* high2) const;
            string_type transform(const charT* low, const charT* high) const;
            long hash(const charT* low, const charT* high) const;

            static locale::id id;

        protected:
            ~collate();
            virtual int do_compare(const charT* low1, const charT* high1,
                                  const charT* low2, const charT* high2) const;
            virtual string_type do_transform(const charT* low, const charT* high) const;
            virtual long do_hash (const charT* low, const charT* high) const;
        };
}

```

The class `collate<charT>` provides features for use in the collation (comparison) and hashing of strings. A locale member function template, `operator()`, uses the collate facet to allow a locale to act directly as the predicate argument for standard algorithms (Clause 27) and containers operating on strings. The specializations required in Table 104 (30.3.1.2.1), namely `collate<char>` and `collate<wchar_t>`, apply lexicographical ordering (27.8.11).

Each function compares a string of characters `*p` in the range `[low, high)`.

30.4.5.1.2 Members

[locale.collate.members]

```

int compare(const charT* low1, const charT* high1,
            const charT* low2, const charT* high2) const;

    Returns: do_compare(low1, high1, low2, high2).

string_type transform(const charT* low, const charT* high) const;

    Returns: do_transform(low, high).

long hash(const charT* low, const charT* high) const;

    Returns: do_hash(low, high).

```

30.4.5.1.3 Virtual functions

[locale.collate.virtuals]

```

int do_compare(const charT* low1, const charT* high1,
               const charT* low2, const charT* high2) const;

    Returns: 1 if the first string is greater than the second, -1 if less, zero otherwise. The specializations
    required in Table 104 (30.3.1.2.1), namely collate<char> and collate<wchar_t>, implement a
    lexicographical comparison (27.8.11).

```

```
string_type do_transform(const charT* low, const charT* high) const;
```

Returns: A `basic_string<charT>` value that, compared lexicographically with the result of calling `transform()` on another string, yields the same result as calling `do_compare()` on the same two strings.²⁵³

```
long do_hash(const charT* low, const charT* high) const;
```

Returns: An integer value equal to the result of calling `hash()` on any other string for which `do_compare()` returns 0 (equal) when passed the two strings.

Recommended practice: The probability that the result equals that for another string which does not compare equal should be very small, approaching $(1.0/\text{numeric\_limits}<\text{unsigned long}>::\text{max}())$.

30.4.5.2 Class template `collate_byname`

[`locale.collate.byname`]

```
namespace std {
    template<class charT>
    class collate_byname : public collate<charT> {
    public:
        using string_type = basic_string<charT>;

        explicit collate_byname(const char*, size_t refs = 0);
        explicit collate_byname(const string&, size_t refs = 0);

    protected:
        ~collate_byname();
    };
}
```

30.4.6 The time category

[`category.time`]

30.4.6.1 General

[`category.time.general`]

Templates `time_get<charT, InputIterator>` and `time_put<charT, OutputIterator>` provide date and time formatting and parsing. All specifications of member functions for `time_put` and `time_get` in the subclauses of 30.4.6 only apply to the specializations required in Tables 104 and 105 (30.3.1.2.1). Their members use their `ios_base&`, `ios_base::iostate&`, and `fill` arguments as described in 30.4, and the `ctype<>` facet, to determine formatting details.

30.4.6.2 Class template `time_get`

[`locale.time.get`]

30.4.6.2.1 General

[`locale.time.get.general`]

```
namespace std {
    class time_base {
    public:
        enum dateorder { no_order, dmy, mdy, ymd, ydm };
    };

    template<class charT, class InputIterator = istreambuf_iterator<charT>>
    class time_get : public locale::facet, public time_base {
    public:
        using char_type = charT;
        using iter_type = InputIterator;

        explicit time_get(size_t refs = 0);

        dateorder date_order() const { return do_date_order(); }
        iter_type get_time(iter_type s, iter_type end, ios_base& f,
                          ios_base::iostate& err, tm* t) const;
        iter_type get_date(iter_type s, iter_type end, ios_base& f,
                          ios_base::iostate& err, tm* t) const;
        iter_type get_weekday(iter_type s, iter_type end, ios_base& f,
                              ios_base::iostate& err, tm* t) const;
        iter_type get_monthname(iter_type s, iter_type end, ios_base& f,
                               ios_base::iostate& err, tm* t) const;
    };
}
```

²⁵³) This function is useful when one string is being compared to many other strings.

```

iter_type get_year(iter_type s, iter_type end, ios_base& f,
                  ios_base::iostate& err, tm* t) const;
iter_type get(iter_type s, iter_type end, ios_base& f,
              ios_base::iostate& err, tm* t, char format, char modifier = 0) const;
iter_type get(iter_type s, iter_type end, ios_base& f,
              ios_base::iostate& err, tm* t, const char_type* fmt,
              const char_type* fmtend) const;

static locale::id id;

protected:
    ~time_get();
    virtual dateorder do_date_order() const;
    virtual iter_type do_get_time(iter_type s, iter_type end, ios_base&,
                                ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_date(iter_type s, iter_type end, ios_base&,
                                ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_weekday(iter_type s, iter_type end, ios_base&,
                                    ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_monthname(iter_type s, iter_type end, ios_base&,
                                       ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_year(iter_type s, iter_type end, ios_base&,
                                  ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get(iter_type s, iter_type end, ios_base& f,
                             ios_base::iostate& err, tm* t, char format, char modifier) const;
};
}

```

`time_get` is used to parse a character sequence, extracting components of a time or date into a `tm` object. Each `get` member parses a format as produced by a corresponding format specifier to `time_put<>::put`. If the sequence being parsed matches the correct format, the corresponding members of the `tm` argument are set to the values used to produce the sequence; otherwise either an error is reported or unspecified values are assigned.²⁵⁴

If the end iterator is reached during parsing by any of the `get()` member functions, the member sets `ios_base::eofbit` in `err`.

30.4.6.2.2 Members

[`locale.time.get.members`]

```
dateorder date_order() const;
```

Returns: `do_date_order()`.

```
iter_type get_time(iter_type s, iter_type end, ios_base& str,
                  ios_base::iostate& err, tm* t) const;
```

Returns: `do_get_time(s, end, str, err, t)`.

```
iter_type get_date(iter_type s, iter_type end, ios_base& str,
                  ios_base::iostate& err, tm* t) const;
```

Returns: `do_get_date(s, end, str, err, t)`.

```
iter_type get_weekday(iter_type s, iter_type end, ios_base& str,
                     ios_base::iostate& err, tm* t) const;
```

```
iter_type get_monthname(iter_type s, iter_type end, ios_base& str,
                       ios_base::iostate& err, tm* t) const;
```

Returns: `do_get_weekday(s, end, str, err, t)` or `do_get_monthname(s, end, str, err, t)`.

```
iter_type get_year(iter_type s, iter_type end, ios_base& str,
                  ios_base::iostate& err, tm* t) const;
```

Returns: `do_get_year(s, end, str, err, t)`.

²⁵⁴) In other words, user confirmation is required for reliable parsing of user-entered dates and times, but machine-generated formats can be parsed reliably. This allows parsers to be aggressive about interpreting user variations on standard formats.

```
iter_type get(iter_type s, iter_type end, ios_base& f, ios_base::iostate& err,
             tm* t, char format, char modifier = 0) const;
```

Returns: `do_get(s, end, f, err, t, format, modifier)`.

```
iter_type get(iter_type s, iter_type end, ios_base& f, ios_base::iostate& err,
             tm* t, const char_type* fmt, const char_type* fmtend) const;
```

Preconditions: `[fmt,fmtend)` is a valid range.

Effects: The function starts by evaluating `err = ios_base::goodbit`. It then enters a loop, reading zero or more characters from `s` at each iteration. Unless otherwise specified below, the loop terminates when the first of the following conditions holds:

- The expression `fmt == fmtend` evaluates to `true`.
- The expression `err == ios_base::goodbit` evaluates to `false`.
- The expression `s == end` evaluates to `true`, in which case the function evaluates `err = ios_base::eofbit | ios_base::failbit`.
- The next element of `fmt` is equal to `'%'`, optionally followed by a modifier character, followed by a conversion specifier character, `format`, together forming a conversion specification valid for the POSIX function `strptime`. If the number of elements in the range `[fmt,fmtend)` is not sufficient to unambiguously determine whether the conversion specification is complete and valid, the function evaluates `err = ios_base::failbit`. Otherwise, the function evaluates `s = do_get(s, end, f, err, t, format, modifier)`, where the value of `modifier` is `'\0'` when the optional modifier is absent from the conversion specification. If `err == ios_base::goodbit` holds after the evaluation of the expression, the function increments `fmt` to point just past the end of the conversion specification and continues looping.
- The expression `isspace(*fmt, f.getloc())` evaluates to `true`, in which case the function first increments `fmt` until `fmt == fmtend || !isspace(*fmt, f.getloc())` evaluates to `true`, then advances `s` until `s == end || !isspace(*s, f.getloc())` is `true`, and finally resumes looping.
- The next character read from `s` matches the element pointed to by `fmt` in a case-insensitive comparison, in which case the function evaluates `++fmt, ++s` and continues looping. Otherwise, the function evaluates `err = ios_base::failbit`.

NOTE The function uses the `ctype<charT>` facet installed in `f`'s locale to determine valid whitespace characters. It is unspecified by what means the function performs case-insensitive comparison or whether multi-character sequences are considered while doing so.

Returns: `s`.

30.4.6.2.3 Virtual functions

[`locale.time.get.virtuals`]

```
dateorder do_date_order() const;
```

Returns: An enumeration value indicating the preferred order of components for those date formats that are composed of day, month, and year.²⁵⁵ Returns `no_order` if the date format specified by `'x'` contains other variable components (e.g., Julian day, week number, week day).

```
iter_type do_get_time(iter_type s, iter_type end, ios_base& str,
                    ios_base::iostate& err, tm* t) const;
```

Effects: Reads characters starting at `s` until it has extracted those `tm` members, and remaining format characters, used by `time_put<>::put` to produce the format specified by `"%H:%M:%S"`, or until it encounters an error or end of sequence.

Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a valid time.

```
iter_type do_get_date(iter_type s, iter_type end, ios_base& str,
                    ios_base::iostate& err, tm* t) const;
```

Effects: Reads characters starting at `s` until it has extracted those `tm` members and remaining format characters used by `time_put<>::put` to produce one of the following formats, or until it encounters an error. The format depends on the value returned by `date_order()` as shown in Table 115.

²⁵⁵) This function is intended as a convenience only, for common formats, and can return `no_order` in valid locales.

Table 115 — `do_get_date` effects [tab:locale.time.get.dogetdate]

<code>date_order()</code>	Format
<code>no_order</code>	"%m%d%y"
<code>dmy</code>	"%d%m%y"
<code>mdy</code>	"%m%d%y"
<code>ymd</code>	"%y%m%d"
<code>ydm</code>	"%y%d%m"

An implementation may also accept additional implementation-defined formats.

Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a valid date.

```
iter_type do_get_weekday(iter_type s, iter_type end, ios_base& str,
                        ios_base::iostate& err, tm* t) const;
iter_type do_get_monthname(iter_type s, iter_type end, ios_base& str,
                          ios_base::iostate& err, tm* t) const;
```

Effects: Reads characters starting at `s` until it has extracted the (perhaps abbreviated) name of a weekday or month. If it finds an abbreviation that is followed by characters that can match a full name, it continues reading until it matches the full name or fails. It sets the appropriate `tm` member accordingly.

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid name.

```
iter_type do_get_year(iter_type s, iter_type end, ios_base& str,
                    ios_base::iostate& err, tm* t) const;
```

Effects: Reads characters starting at `s` until it has extracted an unambiguous year identifier. It is implementation-defined whether two-digit year numbers are accepted, and (if so) what century they are assumed to lie in. Sets the `t->tm_year` member accordingly.

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid year identifier.

```
iter_type do_get(iter_type s, iter_type end, ios_base& f,
                ios_base::iostate& err, tm* t, char format, char modifier) const;
```

Preconditions: `t` points to an object.

Effects: The function starts by evaluating `err = ios_base::goodbit`. It then reads characters starting at `s` until it encounters an error, or until it has extracted and assigned those `tm` members, and any remaining format characters, corresponding to a conversion specification appropriate for the POSIX function `strptime`, formed by concatenating `'%'`, the `modifier` character, when non-NUL, and the `format` character. When the concatenation fails to yield a complete valid directive the function leaves the object pointed to by `t` unchanged and evaluates `err |= ios_base::failbit`. When `s == end` evaluates to `true` after reading a character the function evaluates `err |= ios_base::eofbit`.

For complex conversion specifications such as `%c`, `%x`, or `%X`, or conversion specifications that involve the optional modifiers `E` or `O`, when the function is unable to unambiguously determine some or all `tm` members from the input sequence `[s, end)`, it evaluates `err |= ios_base::eofbit`. In such cases the values of those `tm` members are unspecified and may be outside their valid range.

Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a valid input sequence for the given `format` and `modifier`.

Remarks: It is unspecified whether multiple calls to `do_get()` with the address of the same `tm` object will update the current contents of the object or simply overwrite its members. Portable programs should zero out the object before invoking the function.

30.4.6.3 Class template `time_get_byname`[`locale.time.get.byname`]

```

namespace std {
    template<class charT, class InputIterator = istreambuf_iterator<charT>>
        class time_get_byname : public time_get<charT, InputIterator> {
        public:
            using dateorder = time_base::dateorder;
            using iter_type = InputIterator;

            explicit time_get_byname(const char*, size_t refs = 0);
            explicit time_get_byname(const string&, size_t refs = 0);

        protected:
            ~time_get_byname();
        };
}

```

30.4.6.4 Class template `time_put`[`locale.time.put`]

30.4.6.4.1 General

[`locale.time.put.general`]

```

namespace std {
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
        class time_put : public locale::facet {
        public:
            using char_type = charT;
            using iter_type = OutputIterator;

            explicit time_put(size_t refs = 0);

            // the following is implemented in terms of other member functions.
            iter_type put(iter_type s, ios_base& f, char_type fill, const tm* tmb,
                const charT* pattern, const charT* pat_end) const;
            iter_type put(iter_type s, ios_base& f, char_type fill,
                const tm* tmb, char format, char modifier = 0) const;

            static locale::id id;

        protected:
            ~time_put();
            virtual iter_type do_put(iter_type s, ios_base&, char_type, const tm* t,
                char format, char modifier) const;
        };
}

```

30.4.6.4.2 Members

[`locale.time.put.members`]

```

iter_type put(iter_type s, ios_base& str, char_type fill, const tm* t,
    const charT* pattern, const charT* pat_end) const;
iter_type put(iter_type s, ios_base& str, char_type fill, const tm* t,
    char format, char modifier = 0) const;

```

Effects: The first form steps through the sequence from `pattern` to `pat_end`, identifying characters that are part of a format sequence. Each character that is not part of a format sequence is written to `s` immediately, and each format sequence, as it is identified, results in a call to `do_put`; thus, format elements and other characters are interleaved in the output in the order in which they appear in the pattern. Format sequences are identified by converting each character `c` to a `char` value as if by `ct.narrow(c, 0)`, where `ct` is a reference to `ctype<charT>` obtained from `str.getloc()`. The first character of each sequence is equal to `'%'`, followed by an optional modifier character `mod`²⁵⁶ and a format specifier character `spec` as defined for the function `strftime`. If no modifier character is present, `mod` is zero. For each valid format sequence identified, calls `do_put(s, str, fill, t, spec, mod)`.

The second form calls `do_put(s, str, fill, t, format, modifier)`.

NOTE The `fill` argument can be used in the implementation-defined formats or by derivations. A space character is a reasonable default for this argument.

²⁵⁶) Although the C programming language defines no modifiers, most vendors do.

Returns: An iterator pointing immediately after the last character produced.

30.4.6.4.3 Virtual functions

[`locale.time.put.virtuals`]

```
iter_type do_put(iter_type s, ios_base&, char_type fill, const tm* t,
                char format, char modifier) const;
```

Effects: Formats the contents of the parameter `t` into characters placed on the output sequence `s`. Formatting is controlled by the parameters `format` and `modifier`, interpreted identically as the format specifiers in the string argument to the standard library function `strftime()`, except that the sequence of characters produced for those specifiers that are described as depending on the C locale are instead implementation-defined.

NOTE 1 Interpretation of the `modifier` argument is implementation-defined.

Returns: An iterator pointing immediately after the last character produced.

NOTE 2 The `fill` argument can be used in the implementation-defined formats or by derivations. A space character is a reasonable default for this argument.

Recommended practice: Interpretation of the `modifier` should follow the conventions of ISO/IEC/IEEE 9945:2009. Implementations should refer to other standards such as ISO/IEC/IEEE 9945:2009 for a specification of the character sequences produced for those specifiers described as depending on the C locale.

30.4.6.5 Class template `time_put_byname`

[`locale.time.put.byname`]

```
namespace std {
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
        class time_put_byname : public time_put<charT, OutputIterator> {
        public:
            using char_type = charT;
            using iter_type = OutputIterator;

            explicit time_put_byname(const char*, size_t refs = 0);
            explicit time_put_byname(const string&, size_t refs = 0);

        protected:
            ~time_put_byname();
        };
}
```

30.4.7 The monetary category

[`category.monetary`]

30.4.7.1 General

[`category.monetary.general`]

These templates handle monetary formats. A template parameter indicates whether local or international monetary formats are to be used.

All specifications of member functions for `money_put` and `money_get` in the subclauses of 30.4.7 only apply to the specializations required in Tables 104 and 105 (30.3.1.2.1). Their members use their `ios_base&`, `ios_base::iostate&`, and `fill` arguments as described in 30.4, and the `money_punct<>` and `ctype<>` facets, to determine formatting details.

30.4.7.2 Class template `money_get`

[`locale.money.get`]

30.4.7.2.1 General

[`locale.money.get.general`]

```
namespace std {
    template<class charT, class InputIterator = istreambuf_iterator<charT>>
        class money_get : public locale::facet {
        public:
            using char_type = charT;
            using iter_type = InputIterator;
            using string_type = basic_string<charT>;

            explicit money_get(size_t refs = 0);
```

```

    iter_type get(iter_type s, iter_type end, bool intl,
                  ios_base& f, ios_base::iostate& err,
                  long double& units) const;
    iter_type get(iter_type s, iter_type end, bool intl,
                  ios_base& f, ios_base::iostate& err,
                  string_type& digits) const;

    static locale::id id;

protected:
    ~money_get();
    virtual iter_type do_get(iter_type, iter_type, bool, ios_base&,
                             ios_base::iostate& err, long double& units) const;
    virtual iter_type do_get(iter_type, iter_type, bool, ios_base&,
                             ios_base::iostate& err, string_type& digits) const;
};
}

```

30.4.7.2.2 Members

[locale.money.get.members]

```

iter_type get(iter_type s, iter_type end, bool intl, ios_base& f,
              ios_base::iostate& err, long double& quant) const;
iter_type get(iter_type s, iter_type end, bool intl, ios_base& f,
              ios_base::iostate& err, string_type& quant) const;

```

Returns: do_get(s, end, intl, f, err, quant).

30.4.7.2.3 Virtual functions

[locale.money.get.virtuals]

```

iter_type do_get(iter_type s, iter_type end, bool intl, ios_base& str,
                 ios_base::iostate& err, long double& units) const;
iter_type do_get(iter_type s, iter_type end, bool intl, ios_base& str,
                 ios_base::iostate& err, string_type& digits) const;

```

Effects: Reads characters from *s* to parse and construct a monetary value according to the format specified by a `money_punct<charT, Intl>` facet reference *mp* and the character mapping specified by a `ctype<charT>` facet reference *ct* obtained from the locale returned by `str.getloc()`, and `str.flags()`. If a valid sequence is recognized, does not change *err*; otherwise, sets *err* to `(err|str.failbit)`, or `(err|str.failbit|str.eofbit)` if no more characters are available, and does not change *units* or *digits*. Uses the pattern returned by `mp.neg_format()` to parse all values. The result is returned as an integral value stored in *units* or as a sequence of digits possibly preceded by a minus sign (as produced by `ct.widen(c)` where *c* is '-' or in the range from '0' through '9' (inclusive)) stored in *digits*.

EXAMPLE 1 The sequence \$1,056.23 in a common United States locale would yield, for *units*, 105623, or, for *digits*, "105623".

If `mp.grouping()` indicates that no thousands separators are permitted, any such characters are not read, and parsing is terminated at the point where they first appear. Otherwise, thousands separators are optional; if present, they are checked for correct placement only after all format components have been read.

Where `money_base::space` or `money_base::none` appears as the last element in the format pattern, no whitespace is consumed. Otherwise, where `money_base::space` appears in any of the initial elements of the format pattern, at least one whitespace character is required. Where `money_base::none` appears in any of the initial elements of the format pattern, whitespace is allowed but not required. If `(str.flags() & str.showbase)` is false, the currency symbol is optional and is consumed only if other characters are needed to complete the format; otherwise, the currency symbol is required.

If the first character (if any) in the string *pos* returned by `mp.positive_sign()` or the string *neg* returned by `mp.negative_sign()` is recognized in the position indicated by *sign* in the format pattern, it is consumed and any remaining characters in the string are required after all the other format components.

EXAMPLE 2 If `showbase` is off, then for a *neg* value of "(" and a currency symbol of "L", in "(100 L)" the "L" is consumed; but if *neg* is "-", the "L" in "-100 L" is not consumed.

If `pos` or `neg` is empty, the sign component is optional, and if no sign is detected, the result is given the sign that corresponds to the source of the empty string. Otherwise, the character in the indicated position shall match the first character of `pos` or `neg`, and the result is given the corresponding sign. If the first character of `pos` is equal to the first character of `neg`, or if both strings are empty, the result is given a positive sign.

Digits in the numeric monetary component are extracted and placed in `digits`, or into a character buffer `buf1` for conversion to produce a value for `units`, in the order in which they appear, preceded by a minus sign if and only if the result is negative. The value `units` is produced as if by²⁵⁷

```
for (int i = 0; i < n; ++i)
    buf2[i] = src[find(atoms, atoms+sizeof(src), buf1[i]) - atoms];
buf2[n] = 0;
sscanf(buf2, "%Lf", &units);
```

where `n` is the number of characters placed in `buf1`, `buf2` is a character buffer, and the values `src` and `atoms` are defined as if by

```
static const char src[] = "0123456789-";
charT atoms[sizeof(src)];
ct.widen(src, src + sizeof(src) - 1, atoms);
```

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid monetary quantity.

30.4.7.3 Class template `money_put`

[`locale.money.put`]

30.4.7.3.1 General

[`locale.money.put.general`]

```
namespace std {
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
        class money_put : public locale::facet {
        public:
            using char_type    = charT;
            using iter_type    = OutputIterator;
            using string_type  = basic_string<charT>;

            explicit money_put(size_t refs = 0);

            iter_type put(iter_type s, bool intl, ios_base& f,
                          char_type fill, long double units) const;
            iter_type put(iter_type s, bool intl, ios_base& f,
                          char_type fill, const string_type& digits) const;

            static locale::id id;

        protected:
            ~money_put();
            virtual iter_type do_put(iter_type, bool, ios_base&, char_type fill,
                                    long double units) const;
            virtual iter_type do_put(iter_type, bool, ios_base&, char_type fill,
                                    const string_type& digits) const;
        };
}
```

30.4.7.3.2 Members

[`locale.money.put.members`]

```
iter_type put(iter_type s, bool intl, ios_base& f, char_type fill, long double quant) const;
iter_type put(iter_type s, bool intl, ios_base& f, char_type fill, const string_type& quant) const;
```

Returns: `do_put(s, intl, f, loc, quant)`.

30.4.7.3.3 Virtual functions

[`locale.money.put.virtuals`]

```
iter_type do_put(iter_type s, bool intl, ios_base& str,
                 char_type fill, long double units) const;
```

²⁵⁷) The semantics here are different from `ct.narrow`.

```
iter_type do_put(iter_type s, bool intl, ios_base& str,
                char_type fill, const string_type& digits) const;
```

Effects: Writes characters to `s` according to the format specified by a `money_punct<charT, Intl>` facet reference `mp` and the character mapping specified by a `ctype<charT>` facet reference `ct` obtained from the locale returned by `str.getloc()`, and `str.flags()`. The argument `units` is transformed into a sequence of wide characters as if by

```
ct.widen(buf1, buf1 + sprintf(buf1, "%.0Lf", units), buf2)
```

for character buffers `buf1` and `buf2`. If the first character in `digits` or `buf2` is equal to `ct.widen('')`, then the pattern used for formatting is the result of `mp.neg_format()`; otherwise the pattern is the result of `mp.pos_format()`. Digit characters are written, interspersed with any thousands separators and decimal point specified by the format, in the order they appear (after the optional leading minus sign) in `digits` or `buf2`. In `digits`, only the optional leading minus sign and the immediately subsequent digit characters (as classified according to `ct`) are used; any trailing characters (including digits appearing after a non-digit character) are ignored. Calls `str.width(0)`.

Returns: An iterator pointing immediately after the last character produced.

Remarks: The currency symbol is generated if and only if `(str.flags() & str.showbase)` is nonzero. If the number of characters generated for the specified format is less than the value returned by `str.width()` on entry to the function, then copies of `fill` are inserted as necessary to pad to the specified width. For the value `af` equal to `(str.flags() & str.adjustfield)`, if `(af == str.internal)` is `true`, the fill characters are placed where `none` or `space` appears in the formatting pattern; otherwise if `(af == str.left)` is `true`, they are placed after the other characters; otherwise, they are placed before the other characters.

NOTE It is possible, with some combinations of format patterns and flag values, to produce output that cannot be parsed using `num_get<>::get`.

30.4.7.4 Class template `money_punct`

[`locale.money_punct`]

30.4.7.4.1 General

[`locale.money_punct.general`]

```
namespace std {
    class money_base {
    public:
        enum part { none, space, symbol, sign, value };
        struct pattern { char field[4]; };
    };

    template<class charT, bool International = false>
    class money_punct : public locale::facet, public money_base {
    public:
        using char_type = charT;
        using string_type = basic_string<charT>;

        explicit money_punct(size_t refs = 0);

        charT decimal_point() const;
        charT thousands_sep() const;
        string grouping() const;
        string_type curr_symbol() const;
        string_type positive_sign() const;
        string_type negative_sign() const;
        int frac_digits() const;
        pattern pos_format() const;
        pattern neg_format() const;

        static locale::id id;
        static const bool intl = International;

    protected:
        ~money_punct();
        virtual charT do_decimal_point() const;
        virtual charT do_thousands_sep() const;
```

```

    virtual string      do_grouping()      const;
    virtual string_type do_curr_symbol()   const;
    virtual string_type do_positive_sign() const;
    virtual string_type do_negative_sign() const;
    virtual int         do_frac_digits()   const;
    virtual pattern     do_pos_format()    const;
    virtual pattern     do_neg_format()    const;
};
}

```

The `money_punct<>` facet defines monetary formatting parameters used by `money_get<>` and `money_put<>`. A monetary format is a sequence of four components, specified by a `pattern` value `p`, such that the `part` value `static_cast<part>(p.field[i])` determines the i^{th} component of the format²⁵⁸. In the `field` member of a `pattern` object, each value `symbol`, `sign`, `value`, and either `space` or `none` appears exactly once. The value `none`, if present, is not first; the value `space`, if present, is neither first nor last.

Where `none` or `space` appears, whitespace is permitted in the format, except where `none` appears at the end, in which case no whitespace is permitted. The value `space` indicates that at least one space is required at that position. Where `symbol` appears, the sequence of characters returned by `curr_symbol()` is permitted, and can be required. Where `sign` appears, the first (if any) of the sequence of characters returned by `positive_sign()` or `negative_sign()` (respectively as the monetary value is non-negative or negative) is required. Any remaining characters of the sign sequence are required after all other format components. Where `value` appears, the absolute numeric monetary value is required.

The format of the numeric monetary value is a decimal number:

```

value:
    units fractionalopt
    decimal-point digits

fractional:
    decimal-point digitsopt

```

if `frac_digits()` returns a positive value, or

```

value:
    units

```

otherwise. The symbol `decimal-point` indicates the character returned by `decimal_point()`. The other symbols are defined as follows:

```

units:
    digits
    digits thousands-sep units

digits:
    adigit digitsopt

```

In the syntax specification, the symbol `adigit` is any of the values `ct.widen(c)` for `c` in the range '0' through '9' (inclusive) and `ct` is a reference of type `const ctype<charT>&` obtained as described in the definitions of `money_get<>` and `money_put<>`. The symbol `thousands-sep` is the character returned by `thousands_sep()`. The space character used is the value `ct.widen(' ')`. Whitespace characters are those characters `c` for which `ci.is(space, c)` returns `true`. The number of digits required after the decimal point (if any) is exactly the value returned by `frac_digits()`.

The placement of thousands-separator characters (if any) is determined by the value returned by `grouping()`, defined identically as the member `num_punct<>::do_grouping()`.

30.4.7.4.2 Members

[`locale.money_punct.members`]

```

charT      decimal_point() const;
charT      thousands_sep() const;
string     grouping()      const;
string_type curr_symbol()   const;
string_type positive_sign() const;
string_type negative_sign() const;
int        frac_digits()   const;
pattern    pos_format()    const;

```

²⁵⁸) An array of `char`, rather than an array of `part`, is specified for `pattern::field` purely for efficiency.

```
pattern neg_format() const;
```

Each of these functions *F* returns the result of calling the corresponding virtual member function `do_F()`.

30.4.7.4.3 Virtual functions

[`locale.money_punct.virtuals`]

```
charT do_decimal_point() const;
```

Returns: The radix separator to use in case `do_frac_digits()` is greater than zero.²⁵⁹

```
charT do_thousands_sep() const;
```

Returns: The digit group separator to use in case `do_grouping()` specifies a digit grouping pattern.²⁶⁰

```
string do_grouping() const;
```

Returns: A pattern defined identically as, but not necessarily equal to, the result of `num_punct<charT>::do_grouping()`.²⁶¹

```
string_type do_curr_symbol() const;
```

Returns: A string to use as the currency identifier symbol.

NOTE For specializations where the second template parameter is `true`, this is typically four characters long: a three-letter code as specified by ISO 4217^[1] followed by a space.

```
string_type do_positive_sign() const;
```

```
string_type do_negative_sign() const;
```

Returns: `do_positive_sign()` returns the string to use to indicate a positive monetary value;²⁶² `do_negative_sign()` returns the string to use to indicate a negative value.

```
int do_frac_digits() const;
```

Returns: The number of digits after the decimal radix separator, if any.²⁶³

```
pattern do_pos_format() const;
```

```
pattern do_neg_format() const;
```

Returns: The specializations required in Table 105 (30.3.1.2.1), namely

- `money_punct<char>`,
- `money_punct<wchar_t>`,
- `money_punct<char, true>`, and
- `money_punct<wchar_t, true>`,

return an object of type `pattern` initialized to { `symbol`, `sign`, `none`, `value` }.²⁶⁴

30.4.7.5 Class template `money_punct_byname`

[`locale.money_punct.byname`]

```
namespace std {
    template<class charT, bool Intl = false>
    class money_punct_byname : public money_punct<charT, Intl> {
    public:
        using pattern      = money_base::pattern;
        using string_type = basic_string<charT>;

        explicit money_punct_byname(const char*, size_t refs = 0);
        explicit money_punct_byname(const string&, size_t refs = 0);

    protected:
        ~money_punct_byname();
    };
}
```

²⁵⁹) In common U.S. locales this is `'.'`.

²⁶⁰) In common U.S. locales this is `','`.

²⁶¹) To specify grouping by 3s, the value is `"\003"` not `"3"`.

²⁶²) This is usually the empty string.

²⁶³) In common U.S. locales, this is 2.

²⁶⁴) Note that the international symbol returned by `do_curr_symbol()` usually contains a space, itself; for example, `"USD "`.

30.4.8 The message retrieval category

[category.messages]

30.4.8.1 General

[category.messages.general]

Class `messages<charT>` implements retrieval of strings from message catalogs.

30.4.8.2 Class template messages

[locale.messages]

30.4.8.2.1 General

[locale.messages.general]

```
namespace std {
    class messages_base {
    public:
        using catalog = unspecified signed integer type;
    };

    template<class charT>
    class messages : public locale::facet, public messages_base {
    public:
        using char_type = charT;
        using string_type = basic_string<charT>;

        explicit messages(size_t refs = 0);

        catalog open(const string& fn, const locale&) const;
        string_type get(catalog c, int set, int msgid,
                       const string_type& dfault) const;
        void close(catalog c) const;

        static locale::id id;

    protected:
        ~messages();
        virtual catalog do_open(const string&, const locale&) const;
        virtual string_type do_get(catalog, int set, int msgid,
                                   const string_type& dfault) const;
        virtual void do_close(catalog) const;
    };
}
```

Values of type `messages_base::catalog` usable as arguments to members `get` and `close` can be obtained only by calling member `open`.

30.4.8.2.2 Members

[locale.messages.members]

```
catalog open(const string& name, const locale& loc) const;
```

Returns: `do_open(name, loc)`.

```
string_type get(catalog cat, int set, int msgid, const string_type& dfault) const;
```

Returns: `do_get(cat, set, msgid, dfault)`.

```
void close(catalog cat) const;
```

Effects: Calls `do_close(cat)`.

30.4.8.2.3 Virtual functions

[locale.messages.virtuals]

```
catalog do_open(const string& name, const locale& loc) const;
```

Returns: A value that may be passed to `get()` to retrieve a message from the message catalog identified by the string `name` according to an implementation-defined mapping. The result can be used until it is passed to `close()`.

Returns a value less than 0 if no such catalog can be opened.

Remarks: The locale argument `loc` is used for character set code conversion when retrieving messages, if needed.

```
string_type do_get(catalog cat, int set, int msgid, const string_type& default) const;
```

Preconditions: `cat` is a catalog obtained from `open()` and not yet closed.

Returns: A message identified by arguments `set`, `msgid`, and `default`, according to an implementation-defined mapping. If no such message can be found, returns `default`.

```
void do_close(catalog cat) const;
```

Preconditions: `cat` is a catalog obtained from `open()` and not yet closed.

Effects: Releases unspecified resources associated with `cat`.

Remarks: The limit on such resources, if any, is implementation-defined.

30.4.8.3 Class template `messages_byname`

[`locale.messages.byname`]

```
namespace std {
    template<class charT>
    class messages_byname : public messages<charT> {
    public:
        using catalog      = messages_base::catalog;
        using string_type = basic_string<charT>;

        explicit messages_byname(const char*, size_t refs = 0);
        explicit messages_byname(const string&, size_t refs = 0);

    protected:
        ~messages_byname();
    };
}
```

30.5 C library locales

[`c.locales`]

30.5.1 Header `<clocale>` synopsis

[`clocale.syn`]

```
namespace std {
    struct lconv;

    char* setlocale(int category, const char* locale);
    lconv* localeconv();
}

#define NULL see 17.2.3
#define LC_ALL see below
#define LC_COLLATE see below
#define LC_CTYPE see below
#define LC_MONETARY see below
#define LC_NUMERIC see below
#define LC_TIME see below
```

The contents and meaning of the header `<clocale>` are the same as the C standard library header `<locale.h>`.

30.5.2 Data races

[`clocale.data.races`]

Calls to the function `setlocale` may introduce a data race (16.4.6.10) with other calls to `setlocale` or with calls to the functions listed in Table 116.

See also ISO/IEC 9899:2018, 7.11.

Table 116 — Potential `setlocale` data races [tab:setlocale.data.races]

31 Input/output library [input.output]

31.1 General [input.output.general]

This Clause describes components that C++ programs may use to perform input/output operations.

The following subclauses describe requirements for stream parameters, and components for forward declarations of iostreams, predefined iostreams objects, base iostreams classes, stream buffering, stream formatting and manipulators, string streams, and file streams, as summarized in [Table 117](#).

Table 117 — Input/output library summary [tab:iostreams.summary]

Subclause	Header
31.2 Requirements	
31.3 Forward declarations	<code><iosfwd></code>
31.4 Standard iostream objects	<code><iostream></code>
31.5 Iostreams base classes	<code><ios></code>
31.6 Stream buffers	<code><streambuf></code>
31.7 Formatting and manipulators	<code><istream></code> , <code><ostream></code> , <code><iomanip></code> , <code><print></code>
31.8 String streams	<code><sstream></code>
31.9 Span-based streams	<code><spanstream></code>
31.10 File streams	<code><fstream></code>
31.11 Synchronized output streams	<code><syncstream></code>
31.12 File systems	<code><filesystem></code>
31.13 C library files	<code><stdio></code> , <code><cinttypes></code>

31.2 Iostreams requirements [iostreams.requirements]

31.2.1 Imbue limitations [iostream.limits.imbue]

No function described in [Clause 31](#) except for `ios_base::imbue` and `basic_filebuf::pubimbue` causes any instance of `basic_ios::imbue` or `basic_streambuf::imbue` to be called. If any user function called from a function declared in [Clause 31](#) or as an overriding virtual function of any class declared in [Clause 31](#) calls `imbue`, the behavior is undefined.

31.2.2 Types [stream.types]

```
using streamoff = implementation-defined;
```

The type `streamoff` is a synonym for one of the signed basic integral types of sufficient size to represent the maximum possible file size for the operating system.²⁶⁵

```
using streamsize = implementation-defined;
```

The type `streamsize` is a synonym for one of the signed basic integral types. It is used to represent the number of characters transferred in an I/O operation, or the size of I/O buffers.²⁶⁶

31.2.3 Positioning type limitations [iostreams.limits.pos]

The classes of [Clause 31](#) with template arguments `charT` and `traits` behave as described if `traits::pos_type` and `traits::off_type` are `streampos` and `streamoff` respectively. Except as noted explicitly below, their behavior when `traits::pos_type` and `traits::off_type` are other types is implementation-defined.

NOTE For each of the specializations of `char_traits` defined in [23.2.4](#), `state_type` denotes `mbstate_t`, `pos_type` denotes `fpos<mbstate_t>`, and `off_type` denotes `streamoff`.

In the classes of [Clause 31](#), a template parameter with name `charT` represents a member of the set of types containing `char`, `wchar_t`, and any other implementation-defined character types that meet the requirements for a character on which any of the iostream components can be instantiated.

²⁶⁵) Typically `long long`.

²⁶⁶) Most places where `streamsize` is used would use `size_t` in C, or `ssize_t` in ISO/IEC/IEEE 9945.

31.2.4 Thread safety

[iostreams.threadsafety]

Concurrent access to a stream object (31.8, 31.10), stream buffer object (31.6), or C Library stream (31.13) by multiple threads may result in a data race (6.9.2) unless otherwise specified (31.4).

NOTE Data races result in undefined behavior (6.9.2).

If one thread makes a library call *a* that writes a value to a stream and, as a result, another thread reads this value from the stream through a library call *b* such that this does not result in a data race, then *a*'s write synchronizes with *b*'s read.

31.3 Forward declarations

[iostream.forward]

31.3.1 Header <iosfwd> synopsis

[iosfwd.syn]

```
namespace std {
    template<class charT> struct char_traits;
    template<> struct char_traits<char>;
    template<> struct char_traits<char8_t>;
    template<> struct char_traits<char16_t>;
    template<> struct char_traits<char32_t>;
    template<> struct char_traits<wchar_t>;

    template<class T> class allocator;

    template<class charT, class traits = char_traits<charT>>
        class basic_ios;
    template<class charT, class traits = char_traits<charT>>
        class basic_streambuf;
    template<class charT, class traits = char_traits<charT>>
        class basic_istream;
    template<class charT, class traits = char_traits<charT>>
        class basic_ostream;
    template<class charT, class traits = char_traits<charT>>
        class basic_iostream;

    template<class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>>
        class basic_stringbuf;

using wifstream    = basic_ifstream<wchar_t>;
using wofstream    = basic_ofstream<wchar_t>;
using wfstream     = basic_fstream<wchar_t>;

using wsyncbuf     = basic_syncbuf<wchar_t>;
using wosyncstream = basic_osyncstream<wchar_t>;

template<class state> class fpos;
using streampos    = fpos<char_traits<char>::state_type>;
using wstreampos   = fpos<char_traits<wchar_t>::state_type>;

```

```

using u8streampos = fpos<char_traits<char8_t>::state_type>;
using u16streampos = fpos<char_traits<char16_t>::state_type>;
using u32streampos = fpos<char_traits<char32_t>::state_type>;
}

```

Default template arguments are described as appearing both in `<iosfwd>` and in the synopsis of other headers but it is well-formed to include both `<iosfwd>` and one or more of the other headers.²⁶⁷

31.3.2 Overview

[[iostream.forward.overview](#)]

The class template specialization `basic_ios<charT, traits>` serves as a virtual base class for the class templates `basic_istream`, `basic_ostream`, and class templates derived from them. `basic_iostream` is a class template derived from both `basic_istream<charT, traits>` and `basic_ostream<charT, traits>`.

The class template specialization `basic_streambuf<charT, traits>` serves as a base class for class templates `basic_stringbuf`, `basic_filebuf`, and `basic_syncbuf`.

The class template specialization `basic_istream<charT, traits>` serves as a base class for class templates `basic_istreamstream` and `basic_ifstream`.

The class template specialization `basic_ostream<charT, traits>` serves as a base class for class templates `basic_ostreamstream`, `basic_ofstream`, and `basic_osyncstream`.

The class template specialization `basic_iostream<charT, traits>` serves as a base class for class templates `basic_stringstream` and `basic_fstream`.

NOTE 1 For each of the class templates above, the program is ill-formed if `traits::char_type` is not the same type as `charT` (23.2).

Other *typedef-names* define instances of class templates specialized for `char` or `wchar_t` types.

Specializations of the class template `fpos` are used for specifying file position information.

EXAMPLE The types `streampos` and `wstreampos` are used for positioning streams specialized on `char` and `wchar_t` respectively.

NOTE 2 This synopsis suggests a circularity between `streampos` and `char_traits<char>`. An implementation can avoid this circularity by substituting equivalent types.

31.4 Standard iostream objects

[[iostream.objects](#)]

31.4.1 Header `<iostream>` synopsis

[[iostream.syn](#)]

```

#include <ios>           // see 31.5.1
#include <streambuf>     // see 31.6.1
#include <istream>       // see 31.7.1
#include <ostream>       // see 31.7.2

namespace std {
    extern istream cin;
    extern ostream cout;
    extern ostream cerr;
    extern ostream clog;

    extern wistream wcin;
    extern wostream wcout;
    extern wostream wcerr;
    extern wostream wclog;
}

```

31.4.2 Overview

[[iostream.objects.overview](#)]

In this Clause, the type name `FILE` refers to the type `FILE` declared in `<cstdio>` (31.13.1).

The header `<iostream>` declares objects that associate objects with the standard C streams provided for by the functions declared in `<cstdio>`, and includes all the headers necessary to use these objects.

²⁶⁷) It is the implementation's responsibility to implement headers so that including `<iosfwd>` and other headers does not violate the rules about multiple occurrences of default arguments.

The objects are constructed and the associations are established at some time prior to or during the first time an object of class `ios_base::Init` is constructed, and in any case before the body of `main` (6.9.3.1) begins execution. The objects are not destroyed during program execution.²⁶⁸

Recommended practice: If it is possible for them to do so, implementations should initialize the objects earlier than required.

The results of including `<iostream>` in a translation unit shall be as if `<iostream>` defined an instance of `ios_base::Init` with static storage duration. Each C++ library module (16.4.2.4) in a hosted implementation shall behave as if it contains an interface unit that defines an unexported `ios_base::Init` variable with ordered initialization (6.9.3.3).

NOTE 1 As a result, the definition of that variable is appearance-ordered before any declaration following the point of importation of a C++ library module. Whether such a definition exists is unobservable by a program that does not reference any of the standard iostream objects.

Mixing operations on corresponding wide- and narrow-character streams follows the same semantics as mixing such operations on `FILES`, as specified in the C standard library.

Concurrent access to a synchronized (31.5.2.5) standard iostream object's formatted and unformatted input (31.7.5.2) and output (31.7.6.2) functions or a standard C stream by multiple threads does not result in a data race (6.9.2).

NOTE 2 Unsynchronized concurrent use of these objects and streams by multiple threads can result in interleaved characters.

See also ISO/IEC 9899:2018, 7.21.2.

31.4.3 Narrow stream objects

[`narrow.stream.objects`]

`istream cin;`

The object `cin` controls input from a stream buffer associated with the object `stdin`, declared in `<cstdio>` (31.13.1).

After the object `cin` is initialized, `cin.tie()` returns `&cout`. Its state is otherwise the same as required for `basic_ios<char>::init` (31.5.4.2).

`ostream cout;`

The object `cout` controls output to a stream buffer associated with the object `stdout`, declared in `<cstdio>` (31.13.1).

`ostream cerr;`

The object `cerr` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (31.13.1).

After the object `cerr` is initialized, `cerr.flags() & unitbuf` is nonzero and `cerr.tie()` returns `&cout`. Its state is otherwise the same as required for `basic_ios<char>::init` (31.5.4.2).

`ostream clog;`

The object `clog` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (31.13.1).

31.4.4 Wide stream objects

[`wide.stream.objects`]

`wistream wcin;`

The object `wcin` controls input from a stream buffer associated with the object `stdin`, declared in `<cstdio>` (31.13.1).

After the object `wcin` is initialized, `wcin.tie()` returns `&wcout`. Its state is otherwise the same as required for `basic_ios<wchar_t>::init` (31.5.4.2).

`wostream wcout;`

The object `wcout` controls output to a stream buffer associated with the object `stdout`, declared in `<cstdio>` (31.13.1).

²⁶⁸) Constructors and destructors for objects with static storage duration can access these objects to read input from `stdin` or write output to `stdout` or `stderr`.

wostream wcerr;

The object `wcerr` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (31.13.1).

After the object `wcerr` is initialized, `wcerr.flags()` & `unitbuf` is nonzero and `wcerr.tie()` returns `&wcout`. Its state is otherwise the same as required for `basic_ios<wchar_t>::init` (31.5.4.2).

wostream wlog;

The object `wlog` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (31.13.1).

31.5 Iostreams base classes

[iostreams.base]

31.5.1 Header `<ios>` synopsis

[ios.syn]

```

void unsetf(fmtflags mask);

streamsize precision() const;
streamsize precision(streamsize prec);
streamsize width() const;
streamsize width(streamsize wide);

// 31.5.2.4, locales
locale imbue(const locale& loc);
locale getloc() const;

// 31.5.2.6, storage
static int xalloc();
long& iword(int idx);
void*& pword(int idx);

// destructor
virtual ~ios_base();

// 31.5.2.7, callbacks
enum event { erase_event, imbue_event, copyfmt_event };
using event_callback = void (*)(event, ios_base&, int idx);
void register_callback(event_callback fn, int idx);

ios_base(const ios_base&) = delete;
ios_base& operator=(const ios_base&) = delete;

static bool sync_with_stdio(bool sync = true);

protected:
    ios_base();

private:
    static int index; // exposition only
    long* iarray; // exposition only
    void** parray; // exposition only
};
}

```

`ios_base` defines several member types:

- a type `failure`, defined as either a class derived from `system_error` or a synonym for a class derived from `system_error`;
- a class `init`;
- three bitmask types, `fmtflags`, `iostate`, and `openmode`;
- an enumerated type, `seekdir`.

It maintains several kinds of data:

- state information that reflects the integrity of the stream buffer;
- control information that influences how to interpret (format) input sequences and how to generate (format) output sequences;
- additional information that is stored by the program for its private use.

NOTE For the sake of exposition, the maintained data is presented here as:

- `static int index`, specifies the next available unique index for the integer or pointer arrays maintained for the private use of the program, initialized to an unspecified value;

- `long* iarray`, points to the first element of an arbitrary-length `long` array maintained for the private use of the program;
- `void** parray`, points to the first element of an arbitrary-length pointer array maintained for the private use of the program.

31.5.2.2 Types

[ios.types]

31.5.2.2.1 Class `ios_base::failure`

[ios.failure]

```
namespace std {
    class ios_base::failure : public system_error {
    public:
        explicit failure(const string& msg, const error_code& ec = io_errc::stream);
        explicit failure(const char* msg, const error_code& ec = io_errc::stream);
    };
}
```

An implementation is permitted to define `ios_base::failure` as a synonym for a class with equivalent functionality to class `ios_base::failure` shown in this subclause.

NOTE 1 When `ios_base::failure` is a synonym for another type, that type needs to provide a nested type `failure` to emulate the injected-class-name.

The class `failure` defines the base class for the types of all objects thrown as exceptions, by functions in the `iostreams` library, to report errors detected during stream buffer operations.

When throwing `ios_base::failure` exceptions, implementations should provide values of `ec` that identify the specific reason for the failure.

NOTE 2 Errors arising from the operating system would typically be reported as `system_category()` errors with an error value of the error number reported by the operating system. Errors arising from within the stream library would typically be reported as `error_code(io_errc::stream, iostream_category())`.

```
explicit failure(const string& msg, const error_code& ec = io_errc::stream);
```

Effects: Constructs the base class with `msg` and `ec`.

```
explicit failure(const char* msg, const error_code& ec = io_errc::stream);
```

Effects: Constructs the base class with `msg` and `ec`.

31.5.2.2.2 Type `ios_base::fmtflags`

[ios.fmtflags]

```
using fmtflags = T1;
```

The type `fmtflags` is a bitmask type (16.3.3.3.3). Setting its elements has the effects indicated in Table 118.

Type `fmtflags` also defines the constants indicated in Table 119.

31.5.2.2.3 Type `ios_base::iostate`

[ios.iostate]

```
using iostate = T2;
```

The type `iostate` is a bitmask type (16.3.3.3.3) that contains the elements indicated in Table 120.

Type `iostate` also defines the constant:

- `goodbit`, the value zero.

31.5.2.2.4 Type `ios_base::openmode`

[ios.openmode]

```
using openmode = T3;
```

The type `openmode` is a bitmask type (16.3.3.3.3). It contains the elements indicated in Table 121.

31.5.2.2.5 Type `ios_base::seekdir`

[ios.seekdir]

```
using seekdir = T4;
```

The type `seekdir` is an enumerated type (16.3.3.3.2) that contains the elements indicated in Table 122.

Table 118 — `fmtflags` effects [tab:ios.fmtflags]

Element	Effect(s) if set
<code>boolalpha</code>	insert and extract <code>bool</code> type in alphabetic format
<code>dec</code>	converts integer input or generates integer output in decimal base
<code>fixed</code>	generate floating-point output in fixed-point notation
<code>hex</code>	converts integer input or generates integer output in hexadecimal base
<code>internal</code>	adds fill characters at a designated internal point in certain generated output, or identical to <code>right</code> if no such point is designated
<code>left</code>	adds fill characters on the right (final positions) of certain generated output
<code>oct</code>	converts integer input or generates integer output in octal base
<code>right</code>	adds fill characters on the left (initial positions) of certain generated output
<code>scientific</code>	generates floating-point output in scientific notation
<code>showbase</code>	generates a prefix indicating the numeric base of generated integer output
<code>showpoint</code>	generates a decimal-point character unconditionally in generated floating-point output
<code>showpos</code>	generates a <code>+</code> sign in non-negative generated numeric output
<code>skipws</code>	skips leading whitespace before certain input operations
<code>unitbuf</code>	flushes output after each output operation
<code>uppercase</code>	replaces certain lowercase letters with their uppercase equivalents in generated output

Table 119 — `fmtflags` constants [tab:ios.fmtflags.const]

Constant	Allowable values
<code>adjustfield</code>	<code>left</code> <code>right</code> <code>internal</code>
<code>basefield</code>	<code>dec</code> <code>oct</code> <code>hex</code>
<code>floatfield</code>	<code>scientific</code> <code>fixed</code>

Table 120 — `iostate` effects [tab:ios.iostate]

Element	Effect(s) if set
<code>badbit</code>	indicates a loss of integrity in an input or output sequence (such as an irrecoverable read error from a file);
<code>eofbit</code>	indicates that an input operation reached the end of an input sequence;
<code>failbit</code>	indicates that an input operation failed to read the expected characters, or that an output operation failed to generate the desired characters.

31.5.2.2.6 Class `ios_base::Init`

[ios.init]

```

namespace std {
    class ios_base::Init {
    public:
        Init();
        Init(const Init&) = default;
        ~Init();
        Init& operator=(const Init&) = default;

    private:
        static int init_cnt;           // exposition only
    };
}

```

The class `Init` describes an object whose construction ensures the construction of the eight objects declared in `<iostream>` (31.4) that associate file stream buffers with the standard C streams provided for by the functions declared in `<stdio>` (31.13.1).

Table 121 — `openmode` effects [tab:ios.openmode]

Element	Effect(s) if set
<code>app</code>	seek to end before each write
<code>ate</code>	open and seek to end immediately after opening
<code>binary</code>	perform input and output in binary mode (as opposed to text mode)
<code>in</code>	open for input
<code>noreplace</code>	open in exclusive mode
<code>out</code>	open for output
<code>trunc</code>	truncate an existing stream when opening

Table 122 — `seekdir` effects [tab:ios.seekdir]

Element	Meaning
<code>beg</code>	request a seek (for subsequent input or output) relative to the beginning of the stream
<code>cur</code>	request a seek relative to the current position within the sequence
<code>end</code>	request a seek relative to the current end of the sequence

For the sake of exposition, the maintained data is presented here as:

- `static int init_cnt`, counts the number of constructor and destructor calls for class `Init`, initialized to zero.

`Init();`

Effects: Constructs and initializes the objects `cin`, `cout`, `cerr`, `clog`, `wcin`, `wcout`, `wcerr`, and `wclog` if they have not already been constructed and initialized.

`~Init();`

Effects: If there are no other instances of the class still in existence, calls `cout.flush()`, `cerr.flush()`, `clog.flush()`, `wcout.flush()`, `wcerr.flush()`, `wclog.flush()`.

31.5.2.3 State functions

[fmtflags.state]

`fmtflags flags() const;`

Returns: The format control information for both input and output.

`fmtflags flags(fmtflags fmtfl);`

Postconditions: `fmtfl == flags()`.

Returns: The previous value of `flags()`.

`fmtflags setf(fmtflags fmtfl);`

Effects: Sets `fmtfl` in `flags()`.

Returns: The previous value of `flags()`.

`fmtflags setf(fmtflags fmtfl, fmtflags mask);`

Effects: Clears `mask` in `flags()`, sets `fmtfl & mask` in `flags()`.

Returns: The previous value of `flags()`.

`void unsetf(fmtflags mask);`

Effects: Clears `mask` in `flags()`.

`streamsize precision() const;`

Returns: The precision to generate on certain output conversions.

```
streamsize precision(streamsize prec);
```

Postconditions: `prec == precision()`.

Returns: The previous value of `precision()`.

```
streamsize width() const;
```

Returns: The minimum field width (number of characters) to generate on certain output conversions.

```
streamsize width(streamsize wide);
```

Postconditions: `wide == width()`.

Returns: The previous value of `width()`.

31.5.2.4 Functions

[ios.base.locales]

```
locale imbue(const locale& loc);
```

Effects: Calls each registered callback pair `(fn, idx)` (31.5.2.7) as `(*fn)(imbue_event, *this, idx)` at such a time that a call to `ios_base::getloc()` from within `fn` returns the new locale value `loc`.

Postconditions: `loc == getloc()`.

Returns: The previous value of `getloc()`.

```
locale getloc() const;
```

Returns: If no locale has been imbued, a copy of the global C++ locale, `locale()`, in effect at the time of construction. Otherwise, returns the imbued locale, to be used to perform locale-dependent input and output operations.

31.5.2.5 Static members

[ios.members.static]

```
static bool sync_with_stdio(bool sync = true);
```

Effects: If any input or output operation has occurred using the standard streams prior to the call, the effect is implementation-defined. Otherwise, called with a `false` argument, it allows the standard streams to operate independently of the standard C streams.

Returns: `true` if the previous state of the standard iostream objects (31.4) was synchronized and otherwise returns `false`. The first time it is called, the function returns `true`.

Remarks: When a standard iostream object `str` is *synchronized* with a standard stdio stream `f`, the effect of inserting a character `c` by

```
fputc(f, c);
```

is the same as the effect of

```
str.rdbuf()->sputc(c);
```

for any sequences of characters; the effect of extracting a character `c` by

```
c = fgetc(f);
```

is the same as the effect of

```
c = str.rdbuf()->sgetc();
```

for any sequences of characters; and the effect of pushing back a character `c` by

```
ungetc(c, f);
```

is the same as the effect of

```
str.rdbuf()->sputbackc(c);
```

for any sequence of characters.²⁶⁹

²⁶⁹) This implies that operations on a standard iostream object can be mixed arbitrarily with operations on the corresponding stdio stream. In practical terms, synchronization usually means that a standard iostream object and a standard stdio object share a buffer.

31.5.2.6 Storage functions

[ios.base.storage]

```
static int xalloc();
```

Returns: index ++.

Remarks: Concurrent access to this function by multiple threads does not result in a data race (6.9.2).

```
long& iword(int idx);
```

Preconditions: idx is a value obtained by a call to xalloc.

Effects: If iarray is a null pointer, allocates an array of long of unspecified size and stores a pointer to its first element in iarray. The function then extends the array pointed at by iarray as necessary to include the element iarray[idx]. Each newly allocated element of the array is initialized to zero. The reference returned is invalid after any other operation on the object.²⁷⁰ However, the value of the storage referred to is retained, so that until the next call to copyfmt, calling iword with the same index yields another reference to the same value. If the function fails²⁷¹ and *this is a base class subobject of a basic_ios<> object or subobject, the effect is equivalent to calling basic_ios<>::setstate(badbit) on the derived object (which may throw failure).

Returns: On success iarray[idx]. On failure, a valid long& initialized to 0.

```
void*& pword(int idx);
```

Preconditions: idx is a value obtained by a call to xalloc.

Effects: If parray is a null pointer, allocates an array of pointers to void of unspecified size and stores a pointer to its first element in parray. The function then extends the array pointed at by parray as necessary to include the element parray[idx]. Each newly allocated element of the array is initialized to a null pointer. The reference returned is invalid after any other operation on the object. However, the value of the storage referred to is retained, so that until the next call to copyfmt, calling pword with the same index yields another reference to the same value. If the function fails²⁷² and *this is a base class subobject of a basic_ios<> object or subobject, the effect is equivalent to calling basic_ios<>::setstate(badbit) on the derived object (which may throw failure).

Returns: On success parray[idx]. On failure a valid void*& initialized to 0.

Remarks: After a subsequent call to pword(int) for the same object, the earlier return value may no longer be valid.

31.5.2.7 Callbacks

[ios.base.callback]

```
void register_callback(event_callback fn, int idx);
```

Preconditions: The function fn does not throw exceptions.

Effects: Registers the pair (fn, idx) such that during calls to imbue() (31.5.2.4), copyfmt(), or ~ios_base() (31.5.2.8), the function fn is called with argument idx. Functions registered are called when an event occurs, in opposite order of registration. Functions registered while a callback function is active are not called until the next event.

Remarks: Identical pairs are not merged. A function registered twice will be called twice.

31.5.2.8 Constructors and destructor

[ios.base.cons]

```
ios_base();
```

Effects: Each ios_base member has an indeterminate value after construction. The object's members shall be initialized by calling basic_ios::init before the object's first use or before it is destroyed, whichever comes first; otherwise the behavior is undefined.

```
~ios_base();
```

Effects: Calls each registered callback pair (fn, idx) (31.5.2.7) as (*fn)(erase_event, *this, idx) at such time that any ios_base member function called from within fn has well-defined results. Then, any memory obtained is deallocated.

²⁷⁰) An implementation is free to implement both the integer array pointed at by iarray and the pointer array pointed at by parray as sparse data structures, possibly with a one-element cache for each.

²⁷¹) For example, because it cannot allocate space.

²⁷²) For example, because it cannot allocate space.

31.5.3 Class template fpos**[fpos]****31.5.3.1 General****[fpos.general]**

```

namespace std {
    template<class stateT> class fpos {
    public:
        // 31.5.3.2, members
        stateT state() const;
        void state(stateT);

    private:
        stateT st;           // exposition only
    };
}

```

31.5.3.2 Members**[fpos.members]**

```
void state(stateT s);
```

Effects: Assigns *s* to *st*.

```
stateT state() const;
```

Returns: Current value of *st*.

31.5.3.3 Requirements**[fpos.operations]**

An *fpos* type specifies file position information. It holds a state object whose type is equal to the template parameter *stateT*. Type *stateT* shall meet the *Cpp17DefaultConstructible* (Table 30), *Cpp17CopyConstructible* (Table 32), *Cpp17CopyAssignable* (Table 34), and *Cpp17Destructible* (Table 35) requirements. If *is_trivially_copy_constructible_v<stateT>* is true, then *fpos<stateT>* has a trivial copy constructor. If *is_trivially_copy_assignable_v<stateT>* is true, then *fpos<stateT>* has a trivial copy assignment operator. If *is_trivially_destructible_v<stateT>* is true, then *fpos<stateT>* has a trivial destructor. All specializations of *fpos* meet the *Cpp17DefaultConstructible*, *Cpp17CopyConstructible*, *Cpp17CopyAssignable*, *Cpp17Destructible*, and *Cpp17EqualityComparable* (Table 28) requirements. In addition, the expressions shown in Table 123 are valid and have the indicated semantics. In that table,

- *P* refers to a specialization of *fpos*,
- *p* and *q* refer to values of type *P* or *const P*,
- *p1* and *q1* refer to modifiable lvalues of type *P*,
- *0* refers to type *streamoff*, and
- *o* and *o2* refer to values of type *streamoff* or *const streamoff*.

Table 123 — Position type requirements **[tab:fpos.operations]**

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
<i>P(o)</i>	<i>P</i>	converts from <i>offset</i>	<i>Effects:</i> Value-initializes the state object.
<i>P p(o);</i> <i>P p = o;</i>			<i>Effects:</i> Value-initializes the state object. <i>Postconditions:</i> <i>p == P(o)</i> is true.
<i>P()</i>	<i>P</i>	<i>P(0)</i>	
<i>P p;</i>		<i>P p(0);</i>	
<i>0(p)</i>	<i>streamoff</i>	converts to <i>offset</i>	<i>P(0(p)) == p</i>

Table 123 — Position type requirements (continued)

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
<code>p == q</code>	<code>bool</code>		<i>Remarks:</i> For any two values <code>o</code> and <code>o2</code> , if <code>p</code> is obtained from <code>o</code> converted to <code>P</code> or from a copy of such <code>P</code> value and if <code>q</code> is obtained from <code>o2</code> converted to <code>P</code> or from a copy of such <code>P</code> value, then <code>p == q</code> is true only if <code>o == o2</code> is true.
<code>p != q</code>	<code>bool</code>	<code>!(p == q)</code>	
<code>p + o</code>	<code>P</code>	<code>+ offset</code>	<i>Remarks:</i> With <code>q1 = p + o</code> ;; then: <code>q1 - o == p</code>
<code>p1 += o</code>	<code>P&</code>	<code>+= offset</code>	<i>Remarks:</i> With <code>q1 = p1</code> ; before the <code>+=</code> , then: <code>p1 - o == q1</code>
<code>p - o</code>	<code>P</code>	<code>- offset</code>	<i>Remarks:</i> With <code>q1 = p - o</code> ;; then: <code>q1 + o == p</code>
<code>p1 -= o</code>	<code>P&</code>	<code>-= offset</code>	<i>Remarks:</i> With <code>q1 = p1</code> ; before the <code>-=</code> , then: <code>p1 + o == q1</code>
<code>o + p</code>	convertible to <code>P</code>	<code>p + o</code>	<code>P(o + p) == p + o</code>
<code>p - q</code>	<code>streamoff</code>	distance	<code>p == q + (p - q)</code>

Stream operations that return a value of type `traits::pos_type` return `P(0(-1))` as an invalid value to signal an error. If this value is used as an argument to any `istream`, `ostream`, or `streambuf` member that accepts a value of type `traits::pos_type` then the behavior of that function is undefined.

31.5.4 Class template `basic_ios`

[ios]

31.5.4.1 Overview

[ios.overview]

```

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_ios : public ios_base {
    public:
        using char_type    = charT;
        using int_type      = typename traits::int_type;
        using pos_type      = typename traits::pos_type;
        using off_type      = typename traits::off_type;
        using traits_type    = traits;

        // 31.5.4.4, flags-functions
        explicit operator bool() const;
        bool operator!() const;
        iostate rdstate() const;
        void clear(iostate state = goodbit);
        void setstate(iostate state);
        bool good() const;
        bool eof() const;
        bool fail() const;
        bool bad() const;

        iostate exceptions() const;
        void exceptions(iostate except);

        // 31.5.4.2, constructor/destructor
        explicit basic_ios(basic_streambuf<charT, traits>* sb);
        virtual ~basic_ios();

        // 31.5.4.3, members
        basic_ostream<charT, traits>* tie() const;
        basic_ostream<charT, traits>* tie(basic_ostream<charT, traits>* tiestr);
    };

```

```

basic_streambuf<charT, traits>* rdbuf() const;
basic_streambuf<charT, traits>* rdbuf(basic_streambuf<charT, traits>* sb);

basic_ios& copyfmt(const basic_ios& rhs);

char_type fill() const;
char_type fill(char_type ch);

locale imbue(const locale& loc);

char        narrow(char_type c, char dfault) const;
char_type widen(char c) const;

basic_ios(const basic_ios&) = delete;
basic_ios& operator=(const basic_ios&) = delete;

protected:
    basic_ios();
    void init(basic_streambuf<charT, traits>* sb);
    void move(basic_ios& rhs);
    void move(basic_ios&& rhs);
    void swap(basic_ios& rhs) noexcept;
    void set_rdbuf(basic_streambuf<charT, traits>* sb);
};
}

```

31.5.4.2 Constructors

[basic.ios.cons]

explicit basic_ios(basic_streambuf<charT, traits>* sb);

Effects: Assigns initial values to its member objects by calling `init(sb)`.

basic_ios();

Effects: Leaves its member objects uninitialized. The object shall be initialized by calling `basic_ios::init` before its first use or before it is destroyed, whichever comes first; otherwise the behavior is undefined.

~basic_ios();

Remarks: The destructor does not destroy `rdbuf()`.

void init(basic_streambuf<charT, traits>* sb);

Postconditions: The postconditions of this function are indicated in [Table 124](#).

Table 124 — basic_ios::init() effects [tab:basic.ios.cons]

Element	Value
<code>rdbuf()</code>	<code>sb</code>
<code>tie()</code>	<code>0</code>
<code>rdstate()</code>	<code>goodbit</code> if <code>sb</code> is not a null pointer, otherwise <code>badbit</code> .
<code>exceptions()</code>	<code>goodbit</code>
<code>flags()</code>	<code>skipws dec</code>
<code>width()</code>	<code>0</code>
<code>precision()</code>	<code>6</code>
<code>fill()</code>	<code>widen(' ')</code>
<code>getloc()</code>	a copy of the value returned by <code>locale()</code>
<i>iarray</i>	a null pointer
<i>parray</i>	a null pointer

31.5.4.3 Member functions

[basic.ios.members]

```
basic_ostream<charT, traits>* tie() const;
```

Returns: An output sequence that is *tied* to (synchronized with) the sequence controlled by the stream buffer.

```
basic_ostream<charT, traits>* tie(basic_ostream<charT, traits>* tiestr);
```

Preconditions: If *tiestr* is not null, *tiestr* is not reachable by traversing the linked list of tied stream objects starting from *tiestr->tie()*.

Postconditions: *tiestr == tie()*.

Returns: The previous value of *tie()*.

```
basic_streambuf<charT, traits>* rdbuf() const;
```

Returns: A pointer to the *streambuf* associated with the stream.

```
basic_streambuf<charT, traits>* rdbuf(basic_streambuf<charT, traits>* sb);
```

Effects: Calls *clear()*.

Postconditions: *sb == rdbuf()*.

Returns: The previous value of *rdbuf()*.

```
locale imbue(const locale& loc);
```

Effects: Calls *ios_base::imbue(loc)* (31.5.2.4) and if *rdbuf() != 0* then *rdbuf()->pubimbue(loc)* (31.6.3.3.1).

Returns: The prior value of *ios_base::imbue()*.

```
char narrow(char_type c, char dfault) const;
```

Returns: *use_facet<ctype<char_type>>(getloc()).narrow(c, dfault)*

```
char_type widen(char c) const;
```

Returns: *use_facet<ctype<char_type>>(getloc()).widen(c)*

```
char_type fill() const;
```

Returns: The character used to pad (fill) an output conversion to the specified field width.

```
char_type fill(char_type fillch);
```

Postconditions: *traits::eq(fillch, fill())*.

Returns: The previous value of *fill()*.

```
basic_ios& copyfmt(const basic_ios& rhs);
```

Effects: If (*this == addressof(rhs)*) is true does nothing. Otherwise assigns to the member objects of **this* the corresponding member objects of *rhs* as follows:

- calls each registered callback pair (*fn*, *idx*) as *(*fn)(erase_event, *this, idx)*;
- then, assigns to the member objects of **this* the corresponding member objects of *rhs*, except that
 - *rdstate()*, *rdbuf()*, and *exceptions()* are left unchanged;
 - the contents of arrays pointed at by *pword* and *iword* are copied, not the pointers themselves;²⁷³ and
 - if any newly stored pointer values in **this* point at objects stored outside the object *rhs* and those objects are destroyed when *rhs* is destroyed, the newly stored pointer values are altered to point at newly constructed copies of the objects;
- then, calls each callback pair that was copied from *rhs* as *(*fn)(copyfmt_event, *this, idx)*;
- then, calls *exceptions(rhs.exceptions())*.

²⁷³) This suggests an infinite amount of copying, but the implementation can keep track of the maximum element of the arrays that is nonzero.

NOTE The second pass through the callback pairs permits a copied `pword` value to be zeroed, or to have its referent deep copied or reference counted, or to have other special action taken.

Postconditions: The postconditions of this function are indicated in Table 125.

Table 125 — `basic_ios::copyfmt()` effects [tab:basic.ios.copyfmt]

Element	Value
<code>rdbuf()</code>	<i>unchanged</i>
<code>tie()</code>	<code>rhs.tie()</code>
<code>rdstate()</code>	<i>unchanged</i>
<code>exceptions()</code>	<code>rhs.exceptions()</code>
<code>flags()</code>	<code>rhs.flags()</code>
<code>width()</code>	<code>rhs.width()</code>
<code>precision()</code>	<code>rhs.precision()</code>
<code>fill()</code>	<code>rhs.fill()</code>
<code>getloc()</code>	<code>rhs.getloc()</code>

Returns: `*this`.

```
void move(basic_ios& rhs);
void move(basic_ios&& rhs);
```

Postconditions: `*this` has the state that `rhs` had before the function call, except that `rdbuf()` returns `nullptr`. `rhs` is in a valid but unspecified state, except that `rhs.rdbuf()` returns the same value as it returned before the function call, and `rhs.tie()` returns `nullptr`.

```
void swap(basic_ios& rhs) noexcept;
```

Effects: The states of `*this` and `rhs` are exchanged, except that `rdbuf()` returns the same value as it returned before the function call, and `rhs.rdbuf()` returns the same value as it returned before the function call.

```
void set_rdbuf(basic_streambuf<charT, traits>* sb);
```

Preconditions: `sb != nullptr` is true.

Effects: Associates the `basic_streambuf` object pointed to by `sb` with this stream without calling `clear()`.

Postconditions: `rdbuf() == sb` is true.

Throws: Nothing.

31.5.4.4 Flags functions

[iostate.flags]

```
explicit operator bool() const;
```

Returns: `!fail()`.

```
bool operator!() const;
```

Returns: `fail()`.

```
iostate rdstate() const;
```

Returns: The error state of the stream buffer.

```
void clear(iostate state = goodbit);
```

Effects: If `((state | (rdbuf() ? goodbit : badbit)) & exceptions()) == 0`, returns. Otherwise, the function throws an object of class `ios_base::failure` (31.5.2.2.1), constructed with implementation-defined argument values.

Postconditions: If `rdbuf() != 0` then `state == rdstate()`; otherwise `rdstate() == (state | ios_base::badbit)`.

```
void setstate(iostate state);
```

Effects: Calls `clear(rdstate() | state)` (which may throw `ios_base::failure` (31.5.2.2.1)).

`bool good() const;`

Returns: `rdstate() == 0`

`bool eof() const;`

Returns: true if eofbit is set in `rdstate()`.

`bool fail() const;`

Returns: true if failbit or badbit is set in `rdstate()`.²⁷⁴

`bool bad() const;`

Returns: true if badbit is set in `rdstate()`.

`iostate exceptions() const;`

Returns: A mask that determines what elements set in `rdstate()` cause exceptions to be thrown.

`void exceptions(iostate except);`

Effects: Calls `clear(rdstate())`.

Postconditions: `except == exceptions()`.

31.5.5 `ios_base` manipulators

[std.ios.manip]

31.5.5.1 `fmtflags` manipulators

[fmtflags.manip]

Each function specified in this subclause is a designated addressable function (16.4.5.2.1).

`ios_base& boolalpha(ios_base& str);`

Effects: Calls `str.setf(ios_base::boolalpha)`.

Returns: `str`.

`ios_base& noboolalpha(ios_base& str);`

Effects: Calls `str.unsetf(ios_base::boolalpha)`.

Returns: `str`.

`ios_base& showbase(ios_base& str);`

Effects: Calls `str.setf(ios_base::showbase)`.

Returns: `str`.

`ios_base& noshowbase(ios_base& str);`

Effects: Calls `str.unsetf(ios_base::showbase)`.

Returns: `str`.

`ios_base& showpoint(ios_base& str);`

Effects: Calls `str.setf(ios_base::showpoint)`.

Returns: `str`.

`ios_base& noshowpoint(ios_base& str);`

Effects: Calls `str.unsetf(ios_base::showpoint)`.

Returns: `str`.

`ios_base& showpos(ios_base& str);`

Effects: Calls `str.setf(ios_base::showpos)`.

Returns: `str`.

`ios_base& noshowpos(ios_base& str);`

Effects: Calls `str.unsetf(ios_base::showpos)`.

²⁷⁴) Checking `badbit` also for `fail()` is historical practice.

Returns: `str`.

`ios_base& skipws(ios_base& str);`

Effects: Calls `str.setf(ios_base::skipws)`.

Returns: `str`.

`ios_base& noskipws(ios_base& str);`

Effects: Calls `str.unsetf(ios_base::skipws)`.

Returns: `str`.

`ios_base& uppercase(ios_base& str);`

Effects: Calls `str.setf(ios_base::uppercase)`.

Returns: `str`.

`ios_base& nouppercase(ios_base& str);`

Effects: Calls `str.unsetf(ios_base::uppercase)`.

Returns: `str`.

`ios_base& unitbuf(ios_base& str);`

Effects: Calls `str.setf(ios_base::unitbuf)`.

Returns: `str`.

`ios_base& nouunitbuf(ios_base& str);`

Effects: Calls `str.unsetf(ios_base::unitbuf)`.

Returns: `str`.

31.5.5.2 `adjustfield` manipulators

[`adjustfield.manip`]

Each function specified in this subclause is a designated addressable function ([16.4.5.2.1](#)).

`ios_base& internal(ios_base& str);`

Effects: Calls `str.setf(ios_base::internal, ios_base::adjustfield)`.

Returns: `str`.

`ios_base& left(ios_base& str);`

Effects: Calls `str.setf(ios_base::left, ios_base::adjustfield)`.

Returns: `str`.

`ios_base& right(ios_base& str);`

Effects: Calls `str.setf(ios_base::right, ios_base::adjustfield)`.

Returns: `str`.

31.5.5.3 `basefield` manipulators

[`basefield.manip`]

Each function specified in this subclause is a designated addressable function ([16.4.5.2.1](#)).

`ios_base& dec(ios_base& str);`

Effects: Calls `str.setf(ios_base::dec, ios_base::basefield)`.

Returns: `str`.²⁷⁵

`ios_base& hex(ios_base& str);`

Effects: Calls `str.setf(ios_base::hex, ios_base::basefield)`.

Returns: `str`.

²⁷⁵) The function signature `dec(ios_base&)` can be called by the function signature `basic_ostream& stream::operator<<(ios_base& (*)(ios_base&))` to permit expressions of the form `cout << dec` to change the format flags stored in `cout`.

```
ios_base& oct(ios_base& str);
```

Effects: Calls `str.setf(ios_base::oct, ios_base::basefield)`.

Returns: `str`.

31.5.5.4 floatfield manipulators

[floatfield.manip]

Each function specified in this subclause is a designated addressable function (16.4.5.2.1).

```
ios_base& fixed(ios_base& str);
```

Effects: Calls `str.setf(ios_base::fixed, ios_base::floatfield)`.

Returns: `str`.

```
ios_base& scientific(ios_base& str);
```

Effects: Calls `str.setf(ios_base::scientific, ios_base::floatfield)`.

Returns: `str`.

```
ios_base& hexfloat(ios_base& str);
```

Effects: Calls `str.setf(ios_base::fixed | ios_base::scientific, ios_base::floatfield)`.

Returns: `str`.

NOTE It is not possible to use `ios_base::hex` to specify a hexadecimal floating-point format, because it is not part of `ios_base::floatfield` (Table 119).

```
ios_base& defaultfloat(ios_base& str);
```

Effects: Calls `str.unsetf(ios_base::floatfield)`.

Returns: `str`.

31.5.6 Error reporting

[error.reporting]

```
error_code make_error_code(io_errc e) noexcept;
```

Returns: `error_code(static_cast<int>(e), iostream_category())`.

```
error_condition make_error_condition(io_errc e) noexcept;
```

Returns: `error_condition(static_cast<int>(e), iostream_category())`.

```
const error_category& iostream_category() noexcept;
```

Returns: A reference to an object of a type derived from class `error_category`.

The object's default `error_condition` and equivalent virtual functions shall behave as specified for the class `error_category`. The object's `name` virtual function shall return a pointer to the string "iostream".

31.6 Stream buffers

[stream.buffer]

31.6.1 Header <streambuf> synopsis

[streambuf.syn]

```
namespace std {
    template<class charT, class traits = char_traits<charT>>
        class basic_streambuf;
    using streambuf = basic_streambuf<char>;
    using wstreambuf = basic_streambuf<wchar_t>;
}
```

The header <streambuf> defines types that control input from and output to *character* sequences.

31.6.2 Stream buffer requirements

[streambuf.reqts]

Stream buffers can impose various constraints on the sequences they control. Some constraints are:

- The controlled input sequence can be not readable.
- The controlled output sequence can be not writable.
- The controlled sequences can be associated with the contents of other representations for character sequences, such as external files.

- The controlled sequences can support operations *directly* to or from associated sequences.
- The controlled sequences can impose limitations on how the program can read characters from a sequence, write characters to a sequence, put characters back into an input sequence, or alter the stream position.

Each sequence is characterized by three pointers which, if non-null, all point into the same `charT` array object. The array object represents, at any moment, a (sub)sequence of characters from the sequence. Operations performed on a sequence alter the values stored in these pointers, perform reads and writes directly to or from associated sequences, and alter “the stream position” and conversion state as needed to maintain this subsequence relationship. The three pointers are:

- the *beginning pointer*, or lowest element address in the array (called `xbeg` here);
- the *next pointer*, or next element address that is a current candidate for reading or writing (called `xnext` here);
- the *end pointer*, or first element address beyond the end of the array (called `xend` here).

The following semantic constraints shall always apply for any set of three pointers for a sequence, using the pointer names given immediately above:

- If `xnext` is not a null pointer, then `xbeg` and `xend` shall also be non-null pointers into the same `charT` array, as described above; otherwise, `xbeg` and `xend` shall also be null.
- If `xnext` is not a null pointer and `xnext < xend` for an output sequence, then a *write position* is available. In this case, `*xnext` shall be assignable as the next element to write (to put, or to store a character value, into the sequence).
- If `xnext` is not a null pointer and `xbeg < xnext` for an input sequence, then a *putback position* is available. In this case, `xnext[-1]` shall have a defined value and is the next (preceding) element to store a character that is put back into the input sequence.
- If `xnext` is not a null pointer and `xnext < xend` for an input sequence, then a *read position* is available. In this case, `*xnext` shall have a defined value and is the next element to read (to get, or to obtain a character value, from the sequence).

31.6.3 Class template `basic_streambuf`

[streambuf]

31.6.3.1 General

[streambuf.general]

```
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_streambuf {
    public:
        using char_type    = charT;
        using int_type      = typename traits::int_type;
        using pos_type      = typename traits::pos_type;
        using off_type      = typename traits::off_type;
        using traits_type   = traits;

        virtual ~basic_streambuf();

        // 31.6.3.3.1, locales
        locale pubimbue(const locale& loc);
        locale getloc() const;

        // 31.6.3.3.2, buffer and positioning
        basic_streambuf* pubsetbuf(char_type* s, streamsize n);
        pos_type pubseekoff(off_type off, ios_base::seekdir way,
                           ios_base::openmode which
                           = ios_base::in | ios_base::out);
        pos_type pubseekpos(pos_type sp,
                           ios_base::openmode which
                           = ios_base::in | ios_base::out);
        int pubsync();
    };
}
```

```

// get and put areas
// 31.6.3.3.3, get area
streamsize in_avail();
int_type snextc();
int_type sbumpc();
int_type sgetc();
streamsize sgetn(char_type* s, streamsize n);

// 31.6.3.3.4, putback
int_type sputbackc(char_type c);
int_type sungetc();

// 31.6.3.3.5, put area
int_type sputc(char_type c);
streamsize sputn(const char_type* s, streamsize n);

protected:
basic_streambuf();
basic_streambuf(const basic_streambuf& rhs);
basic_streambuf& operator=(const basic_streambuf& rhs);

void swap(basic_streambuf& rhs);

// 31.6.3.4.2, get area access
char_type* eback() const;
char_type* gptr() const;
char_type* egptr() const;
void gbump(int n);
void setg(char_type* gbeg, char_type* gnext, char_type* gend);

// 31.6.3.4.3, put area access
char_type* pbase() const;
char_type* pptr() const;
char_type* ep_ptr() const;
void pbump(int n);
void setp(char_type* pbeg, char_type* pend);

// 31.6.3.5, virtual functions
// 31.6.3.5.1, locales
virtual void imbue(const locale& loc);

// 31.6.3.5.2, buffer management and positioning
virtual basic_streambuf* setbuf(char_type* s, streamsize n);
virtual pos_type seekoff(off_type off, ios_base::seekdir way,
                        ios_base::openmode which
                        = ios_base::in | ios_base::out);
virtual pos_type seekpos(pos_type sp,
                        ios_base::openmode which
                        = ios_base::in | ios_base::out);
virtual int sync();

// 31.6.3.5.3, get area
virtual streamsize showmanyc();
virtual streamsize xsgetn(char_type* s, streamsize n);
virtual int_type underflow();
virtual int_type uflow();

// 31.6.3.5.4, putback
virtual int_type pbackfail(int_type c = traits::eof());

// 31.6.3.5.5, put area
virtual streamsize xsputn(const char_type* s, streamsize n);
virtual int_type overflow(int_type c = traits::eof());

```

```
};
}
```

The class template `basic_streambuf` serves as an abstract base class for deriving various *stream buffers* whose objects each control two *character sequences*:

- a character *input sequence*;
- a character *output sequence*.

31.6.3.2 Constructors

[streambuf.cons]

```
basic_streambuf();
```

Effects: Initializes:²⁷⁶

- all pointer member objects to null pointers,
- the `getloc()` member to a copy of the global locale, `locale()`, at the time of construction.

Remarks: Once the `getloc()` member is initialized, results of calling locale member functions, and of members of facets so obtained, can safely be cached until the next time the member `imbue` is called.

```
basic_streambuf(const basic_streambuf& rhs);
```

Postconditions:

- `eback() == rhs.eback()`
- `gptr() == rhs.gptr()`
- `egptr() == rhs.egptr()`
- `pbase() == rhs.pbase()`
- `pptr() == rhs.pptr()`
- `epptr() == rhs.epptr()`
- `getloc() == rhs.getloc()`

```
~basic_streambuf();
```

Effects: None.

31.6.3.3 Public member functions

[streambuf.members]

31.6.3.3.1 Locales

[streambuf.locales]

```
locale pubimbue(const locale& loc);
```

Effects: Calls `imbue(loc)`.

Postconditions: `loc == getloc()`.

Returns: Previous value of `getloc()`.

```
locale getloc() const;
```

Returns: If `pubimbue()` has ever been called, then the last value of `loc` supplied, otherwise the current global locale, `locale()`, in effect at the time of construction. If called after `pubimbue()` has been called but before `pubimbue` has returned (i.e., from within the call of `imbue()`) then it returns the previous value.

31.6.3.3.2 Buffer management and positioning

[streambuf.buffer]

```
basic_streambuf* pubsetbuf(char_type* s, streamsize n);
```

Returns: `setbuf(s, n)`.

```
pos_type pubseekoff(off_type off, ios_base::seekdir way,
ios_base::openmode which
= ios_base::in | ios_base::out);
```

Returns: `seekoff(off, way, which)`.

²⁷⁶) The default constructor is protected for class `basic_streambuf` to assure that only objects for classes derived from this class can be constructed.

```
pos_type pubseekpos(pos_type sp,
                    ios_base::openmode which
                    = ios_base::in | ios_base::out);
```

Returns: seekpos(sp, which).

```
int pubsync();
```

Returns: sync().

31.6.3.3.3 Get area

[streambuf.pub.get]

```
streamsize in_avail();
```

Returns: If a read position is available, returns `egptr() - gptr()`. Otherwise returns `showmanyc()` (31.6.3.5.3).

```
int_type snextc();
```

Effects: Calls `sbumpc()`.

Returns: If that function returns `traits::eof()`, returns `traits::eof()`. Otherwise, returns `sgetc()`.

```
int_type sbumpc();
```

Effects: If the input sequence read position is not available, returns `uflow()`. Otherwise, returns `traits::to_int_type(*gptr())` and increments the next pointer for the input sequence.

```
int_type sgetc();
```

Returns: If the input sequence read position is not available, returns `underflow()`. Otherwise, returns `traits::to_int_type(*gptr())`.

```
streamsize sgetn(char_type* s, streamsize n);
```

Returns: `xsgetn(s, n)`.

31.6.3.3.4 Putback

[streambuf.pub.pback]

```
int_type sputbackc(char_type c);
```

Effects: If the input sequence putback position is not available, or if `traits::eq(c, gptr()[-1])` is false, returns `pbackfail(traits::to_int_type(c))`. Otherwise, decrements the next pointer for the input sequence and returns `traits::to_int_type(*gptr())`.

```
int_type sungetc();
```

Effects: If the input sequence putback position is not available, returns `pbackfail()`. Otherwise, decrements the next pointer for the input sequence and returns `traits::to_int_type(*gptr())`.

31.6.3.3.5 Put area

[streambuf.pub.put]

```
int_type sputc(char_type c);
```

Effects: If the output sequence write position is not available, returns `overflow(traits::to_int_type(c))`. Otherwise, stores `c` at the next pointer for the output sequence, increments the pointer, and returns `traits::to_int_type(c)`.

```
streamsize sputn(const char_type* s, streamsize n);
```

Returns: `xspun(s, n)`.

31.6.3.4 Protected member functions

[streambuf.protected]

31.6.3.4.1 Assignment

[streambuf.assign]

```
basic_streambuf& operator=(const basic_streambuf& rhs);
```

Postconditions:

- `eback() == rhs.eback()`
- `gptr() == rhs.gptr()`
- `egptr() == rhs.egptr()`

```

— pbase() == rhs.pbase()
— pptr() == rhs.pptr()
— epptr() == rhs.epptr()
— getloc() == rhs.getloc()

```

Returns: **this*.

```
void swap(basic_streambuf& rhs);
```

Effects: Swaps the data members of *rhs* and **this*.

31.6.3.4.2 Get area access

[streambuf.get.area]

```
char_type* eback() const;
```

Returns: The beginning pointer for the input sequence.

```
char_type* gptr() const;
```

Returns: The next pointer for the input sequence.

```
char_type* egptr() const;
```

Returns: The end pointer for the input sequence.

```
void gbump(int n);
```

Effects: Adds *n* to the next pointer for the input sequence.

```
void setg(char_type* gbeg, char_type* gnext, char_type* gend);
```

Postconditions: *gbeg == eback()*, *gnext == gptr()*, and *gend == egptr()* are all true.

31.6.3.4.3 Put area access

[streambuf.put.area]

```
char_type* pbase() const;
```

Returns: The beginning pointer for the output sequence.

```
char_type* pptr() const;
```

Returns: The next pointer for the output sequence.

```
char_type* epptr() const;
```

Returns: The end pointer for the output sequence.

```
void pbump(int n);
```

Effects: Adds *n* to the next pointer for the output sequence.

```
void setp(char_type* pbeg, char_type* pend);
```

Postconditions: *pbeg == pbase()*, *pbeg == pptr()*, and *pend == epptr()* are all true.

31.6.3.5 Virtual functions

[streambuf.virtuals]

31.6.3.5.1 Locales

[streambuf.virt.locales]

```
void imbue(const locale&);
```

Effects: Change any translations based on locale.

Remarks: Allows the derived class to be informed of changes in locale at the time they occur. Between invocations of this function a class derived from *streambuf* can safely cache results of calls to locale functions and to members of facets so obtained.

Default behavior: Does nothing.

31.6.3.5.2 Buffer management and positioning

[streambuf.virt.buffer]

```
basic_streambuf* setbuf(char_type* s, streamsize n);
```

Effects: Influences stream buffering in a way that is defined separately for each class derived from *basic_streambuf* in this Clause (31.8.2.5, 31.10.2.5).

Default behavior: Does nothing. Returns `this`.

```
pos_type seekoff(off_type off, ios_base::seekdir way,
                ios_base::openmode which
                = ios_base::in | ios_base::out);
```

Effects: Alters the stream positions within one or more of the controlled sequences in a way that is defined separately for each class derived from `basic_streambuf` in this Clause (31.8.2.5, 31.10.2.5).

Default behavior: Returns `pos_type(off_type(-1))`.

```
pos_type seekpos(pos_type sp,
                ios_base::openmode which
                = ios_base::in | ios_base::out);
```

Effects: Alters the stream positions within one or more of the controlled sequences in a way that is defined separately for each class derived from `basic_streambuf` in this Clause (31.8.2, 31.10.2).

Default behavior: Returns `pos_type(off_type(-1))`.

```
int sync();
```

Effects: Synchronizes the controlled sequences with the arrays. That is, if `pbase()` is non-null the characters between `pbase()` and `pptr()` are written to the controlled sequence. The pointers may then be reset as appropriate.

Returns: `-1` on failure. What constitutes failure is determined by each derived class (31.10.2.5).

Default behavior: Returns zero.

31.6.3.5.3 Get area

[`streambuf.virt.get`]

```
streamsize showmanyc();277
```

Returns: An estimate of the number of characters available in the sequence, or `-1`. If it returns a positive value, then successive calls to `underflow()` will not return `traits::eof()` until at least that number of characters have been extracted from the stream. If `showmanyc()` returns `-1`, then calls to `underflow()` or `uflow()` will fail.²⁷⁸

Default behavior: Returns zero.

Remarks: Uses `traits::eof()`.

```
streamsize xsgetn(char_type* s, streamsize n);
```

Effects: Assigns up to `n` characters to successive elements of the array whose first element is designated by `s`. The characters assigned are read from the input sequence as if by repeated calls to `sbumpc()`. Assigning stops when either `n` characters have been assigned or a call to `sbumpc()` would return `traits::eof()`.

Returns: The number of characters assigned.²⁷⁹

Remarks: Uses `traits::eof()`.

```
int_type underflow();
```

The *pending sequence* of characters is defined as the concatenation of

- the empty sequence if `gptr()` is null, otherwise the characters in `[gptr(), egptr())`, followed by
- some (possibly empty) sequence of characters read from the input sequence.

The *result character* is the first character of the pending sequence if it is non-empty, otherwise the next character that would be read from the input sequence.

The *backup sequence* is the empty sequence if `eback()` is null, otherwise the characters in `[eback(), gptr())`.

²⁷⁷) The morphemes of `showmanyc` are “es-how-many-see”, not “show-manic”.

²⁷⁸) `underflow` or `uflow` can fail by throwing an exception prematurely. The intention is not only that the calls will not return `eof()` but that they will return “immediately”.

²⁷⁹) Classes derived from `basic_streambuf` can provide more efficient ways to implement `xsgetn()` and `xsputn()` by overriding these definitions from the base class.

Effects: The function sets up the `gptr()` and `egptr()` such that if the pending sequence is non-empty, then `egptr()` is non-null and the characters in `[gptr(), egptr())` are the characters in the pending sequence, otherwise either `gptr()` is null or `gptr() == egptr()`.

If `eback()` and `gptr()` are non-null then the function is not constrained as to their contents, but the “usual backup condition” is that either

- the backup sequence contains at least `gptr() - eback()` characters, in which case the characters in `[eback(), gptr())` agree with the last `gptr() - eback()` characters of the backup sequence, or
- the characters in `[gptr() - n, gptr())` agree with the backup sequence (where `n` is the length of the backup sequence).

Returns: `traits::to_int_type(c)`, where `c` is the first character of the pending sequence, without moving the input sequence position past it. If the pending sequence is null then the function returns `traits::eof()` to indicate failure.

Default behavior: Returns `traits::eof()`.

Remarks: The public members of `basic_streambuf` call this virtual function only if `gptr()` is null or `gptr() >= egptr()`.

```
int_type uflow();
```

Preconditions: The constraints are the same as for `underflow()`, except that the result character is transferred from the pending sequence to the backup sequence, and the pending sequence is not empty before the transfer.

Default behavior: Calls `underflow()`. If `underflow()` returns `traits::eof()`, returns `traits::eof()`. Otherwise, returns the value of `traits::to_int_type(*gptr())` and increments the value of the next pointer for the input sequence.

Returns: `traits::eof()` to indicate failure.

31.6.3.5.4 Putback

[`streambuf.virt.pback`]

```
int_type pbackfail(int_type c = traits::eof());
```

The pending sequence is defined as for `underflow()`, with the modifications that

- If `traits::eq_int_type(c, traits::eof())` returns `true`, then the input sequence is backed up one character before the pending sequence is determined.
- If `traits::eq_int_type(c, traits::eof())` returns `false`, then `c` is prepended. Whether the input sequence is backed up or modified in any other way is unspecified.

Postconditions: On return, the constraints of `gptr()`, `eback()`, and `pptr()` are the same as for `underflow()`.

Returns: `traits::eof()` to indicate failure. Failure may occur because the input sequence cannot be backed up, or if for some other reason the pointers cannot be set consistent with the constraints. `pbackfail()` is called only when put back has really failed.

Returns some value other than `traits::eof()` to indicate success.

Default behavior: Returns `traits::eof()`.

Remarks: The public functions of `basic_streambuf` call this virtual function only when `gptr()` is null, `gptr() == eback()`, or `traits::eq(traits::to_char_type(c), gptr()[−1])` returns `false`. Other calls shall also satisfy that constraint.

31.6.3.5.5 Put area

[`streambuf.virt.put`]

```
streamsize xsputn(const char_type* s, streamsize n);
```

Effects: Writes up to `n` characters to the output sequence as if by repeated calls to `sputc(c)`. The characters written are obtained from successive elements of the array whose first element is designated by `s`. Writing stops when either `n` characters have been written or a call to `sputc(c)` would return `traits::eof()`. It is unspecified whether the function calls `overflow()` when `pptr() == epptr()` becomes `true` or whether it achieves the same effects by other means.

Returns: The number of characters written.

```
int_type overflow(int_type c = traits::eof());
```

Effects: Consumes some initial subsequence of the characters of the *pending sequence*. The pending sequence is defined as the concatenation of

- the empty sequence if `pbase()` is null, otherwise the `pptr() - pbase()` characters beginning at `pbase()`, followed by
- the empty sequence if `traits::eq_int_type(c, traits::eof())` returns `true`, otherwise the sequence consisting of `c`.

Preconditions: Every overriding definition of this virtual function obeys the following constraints:

- The effect of consuming a character on the associated output sequence is specified.²⁸⁰
- Let `r` be the number of characters in the pending sequence not consumed. If `r` is nonzero then `pbase()` and `pptr()` are set so that: `pptr() - pbase() == r` and the `r` characters starting at `pbase()` are the associated output stream. In case `r` is zero (all characters of the pending sequence have been consumed) then either `pbase()` is set to `nullptr`, or `pbase()` and `pptr()` are both set to the same non-null value.
- The function may fail if either appending some character to the associated output stream fails or if it is unable to establish `pbase()` and `pptr()` according to the above rules.

Returns: `traits::eof()` or throws an exception if the function fails.

Otherwise, returns some value other than `traits::eof()` to indicate success.²⁸¹

Default behavior: Returns `traits::eof()`.

Remarks: The member functions `sputc()` and `sputn()` call this function in case that no room can be found in the put buffer enough to accommodate the argument character sequence.

31.7 Formatting and manipulators

[iostream.format]

31.7.1 Header <iostream> synopsis

[istream.syn]

```
namespace std {
    template<class charT, class traits = char_traits<charT>>
        class basic_istream;

    using istream = basic_istream<char>;
    using wistream = basic_istream<wchar_t>;

    template<class charT, class traits = char_traits<charT>>
        class basic_iostream;

```

31.7.5 Input streams

[input.streams]

31.7.5.1 General

[input.streams.general]

The header `<istream>` defines two class templates and a function template that control input from a stream buffer, along with a function template that extracts from stream rvalues.

31.7.5.2 Class template `basic_istream`

[istream]

31.7.5.2.1 General

[istream.general]

When a function is specified with a type placeholder of *extended-floating-point-type*, the implementation provides overloads for all cv-unqualified extended floating-point types (6.8.2) in lieu of *extended-floating-point-type*.

```

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_istream : virtual public basic_ios<charT, traits> {
    public:
        // types (inherited from basic_ios (31.5.4))
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;

        // 31.7.5.2.2, constructor/destructor
        explicit basic_istream(basic_streambuf<charT, traits>* sb);
        virtual ~basic_istream();

        // 31.7.5.2.4, prefix/suffix
        class sentry;

        // 31.7.5.3, formatted input
        basic_istream& operator>>(basic_istream& (*pf)(basic_istream&));
        basic_istream& operator>>(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&));
        basic_istream& operator>>(ios_base& (*pf)(ios_base&));

        basic_istream& operator>>(bool& n);
        basic_istream& operator>>(short& n);
        basic_istream& operator>>(unsigned short& n);
        basic_istream& operator>>(int& n);
        basic_istream& operator>>(unsigned int& n);
        basic_istream& operator>>(long& n);
        basic_istream& operator>>(unsigned long& n);
        basic_istream& operator>>(long long& n);
        basic_istream& operator>>(unsigned long long& n);
        basic_istream& operator>>(float& f);
        basic_istream& operator>>(double& f);
        basic_istream& operator>>(long double& f);
        basic_istream& operator>>(extended-floating-point-type& f);

        basic_istream& operator>>(void*& p);
        basic_istream& operator>>(basic_streambuf<char_type, traits>* sb);
    };
}

```

```

// 31.7.5.4, unformatted input
streamsize gcount() const;
int_type get();
basic_istream& get(char_type& c);
basic_istream& get(char_type* s, streamsize n);
basic_istream& get(char_type* s, streamsize n, char_type delim);
basic_istream& get(basic_streambuf<char_type, traits>& sb);
basic_istream& get(basic_streambuf<char_type, traits>& sb, char_type delim);

basic_istream& getline(char_type* s, streamsize n);
basic_istream& getline(char_type* s, streamsize n, char_type delim);

basic_istream& ignore(streamsize n = 1, int_type delim = traits::eof());
int_type peek();
basic_istream& read (char_type* s, streamsize n);
streamsize readsome(char_type* s, streamsize n);

basic_istream& putback(char_type c);
basic_istream& unget();
int sync();

pos_type tellg();
basic_istream& seekg(pos_type);
basic_istream& seekg(off_type, ios_base::seekdir);

protected:
// 31.7.5.2.2, copy/move constructor
basic_istream(const basic_istream&) = delete;
basic_istream(basic_istream&& rhs);

// 31.7.5.2.3, assignment and swap
basic_istream& operator=(const basic_istream&) = delete;
basic_istream& operator=(basic_istream&& rhs);
void swap(basic_istream& rhs);
};

// 31.7.5.3.3, character extraction templates
template<class charT, class traits>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>&, charT&);
template<class traits>
basic_istream<char, traits>& operator>>(basic_istream<char, traits>&, unsigned char&);
template<class traits>
basic_istream<char, traits>& operator>>(basic_istream<char, traits>&, signed char&);

template<class charT, class traits, size_t N>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>&, charT(&)[N]);
template<class traits, size_t N>
basic_istream<char, traits>& operator>>(basic_istream<char, traits>&, unsigned char(&)[N]);
template<class traits, size_t N>
basic_istream<char, traits>& operator>>(basic_istream<char, traits>&, signed char(&)[N]);
}

```

The class template `basic_istream` defines a number of member function signatures that assist in reading and interpreting input from sequences controlled by a stream buffer.

Two groups of member function signatures share common properties: the *formatted input functions* (or *extractors*) and the *unformatted input functions*. Both groups of input functions are described as if they obtain (or *extract*) input *characters* by calling `rdbuf()->sbumpc()` or `rdbuf()->sgetc()`. They may use other public members of `istream`.

31.7.5.2.2 Constructors

[istream.cons]

```
explicit basic_istream(basic_streambuf<charT, traits>* sb);
```

Effects: Initializes the base class subobject with `basic_ios::init(sb)` (31.5.4.2).

Postconditions: `gcount() == 0`.

```
basic_istream(basic_istream&& rhs);
```

Effects: Default constructs the base class, copies the `gcount()` from `rhs`, calls `basic_ios<charT, traits>::move(rhs)` to initialize the base class, and sets the `gcount()` for `rhs` to 0.

```
virtual ~basic_istream();
```

Remarks: Does not perform any operations of `rdbuf()`.

31.7.5.2.3 Assignment and swap

[istream.assign]

```
basic_istream& operator=(basic_istream&& rhs);
```

Effects: Equivalent to: `swap(rhs)`.

Returns: `*this`.

```
void swap(basic_istream& rhs);
```

Effects: Calls `basic_ios<charT, traits>::swap(rhs)`. Exchanges the values returned by `gcount()` and `rhs.gcount()`.

31.7.5.2.4 Class `basic_istream::sentry`

[istream.sentry]

```
namespace std {
    template<class charT, class traits>
    class basic_istream<charT, traits>::sentry {
        bool ok_; // exposition only

    public:
        explicit sentry(basic_istream& is, bool noskipws = false);
        ~sentry();
        explicit operator bool() const { return ok_; }
        sentry(const sentry&) = delete;
        sentry& operator=(const sentry&) = delete;
    };
}
```

The class `sentry` defines a class that is responsible for doing exception safe prefix and suffix operations.

```
explicit sentry(basic_istream& is, bool noskipws = false);
```

Effects: If `is.good()` is false, calls `is.setstate(failbit)`. Otherwise, prepares for formatted or unformatted input. First, if `is.tie()` is not a null pointer, the function calls `is.tie()->flush()` to synchronize the output sequence with any associated external C stream. Except that this call can be suppressed if the put area of `is.tie()` is empty. Further an implementation is allowed to defer the call to `flush` until a call of `is.rdbuf()->underflow()` occurs. If no such call occurs before the `sentry` object is destroyed, the call to `flush` may be eliminated entirely.²⁸² If `noskipws` is zero and `is.flags() & ios_base::skipws` is nonzero, the function extracts and discards each character as long as the next available input character `c` is a whitespace character. If `is.rdbuf()->sgetc()` or `is.rdbuf()->sgetc()` returns `traits::eof()`, the function calls `setstate(failbit | eofbit)` (which may throw `ios_base::failure`).

Remarks: The constructor

```
explicit sentry(basic_istream& is, bool noskipws = false)
```

uses the currently imbued locale in `is`, to determine whether the next input character is whitespace or not.

To decide if the character `c` is a whitespace character, the constructor performs as if it executes the following code fragment:

```
const ctype<charT>& ctype = use_facet<ctype<charT>>(is.getloc());
if (ctype.is(ctype.space, c) != 0)
    // c is a whitespace character.
```

²⁸²⁾ This will be possible only in functions that are part of the library. The semantics of the constructor used in user code is as specified.

If, after any preparation is completed, `is.good()` is `true`, `ok_ != false` otherwise, `ok_ == false`. During preparation, the constructor may call `setstate(failbit)` (which may throw `ios_base::failure` (31.5.4.4)).²⁸³

```
~sentry();
```

Effects: None.

```
explicit operator bool() const;
```

Returns: `ok_`.

31.7.5.3 Formatted input functions

[istream.formatted]

31.7.5.3.1 Common requirements

[istream.formatted.reqmts]

Each formatted input function begins execution by constructing an object of type `ios_base::iostate`, termed the local error state, and initializing it to `ios_base::goodbit`. It then creates an object of class `sentry` with the `noskipws` (second) argument `false`. If the `sentry` object returns `true`, when converted to a value of type `bool`, the function endeavors to obtain the requested input. Otherwise, if the `sentry` constructor exits by throwing an exception or if the `sentry` object produces `false` when converted to a value of type `bool`, the function returns without attempting to obtain any input. If `rdbuf()->sbumpc()` or `rdbuf()->sgetc()` returns `traits::eof()`, then `ios_base::eofbit` is set in the local error state and the input function stops trying to obtain the requested input. If an exception is thrown during input then `ios_base::badbit` is set in the local error state, `*this`'s error state is set to the local error state, and the exception is rethrown if `(exceptions() & badbit) != 0`. After extraction is done, the input function calls `setstate`, which sets `*this`'s error state to the local error state, and may throw an exception. In any case, the formatted input function destroys the `sentry` object. If no exception has been thrown, it returns `*this`.

31.7.5.3.2 Arithmetic extractors

[istream.formatted.arithmetic]

```
basic_istream& operator>>(unsigned short& val);
basic_istream& operator>>(unsigned int& val);
basic_istream& operator>>(long& val);
basic_istream& operator>>(unsigned long& val);
basic_istream& operator>>(long long& val);
basic_istream& operator>>(unsigned long long& val);
basic_istream& operator>>(float& val);
basic_istream& operator>>(double& val);
basic_istream& operator>>(long double& val);
basic_istream& operator>>(bool& val);
basic_istream& operator>>(void*& val);
```

As in the case of the inserters, these extractors depend on the locale's `num_get<>` (30.4.3.2) object to perform parsing the input stream data. These extractors behave as formatted input functions (as described in 31.7.5.3.1). After a `sentry` object is constructed, the conversion occurs as if performed by the following code fragment, where `state` represents the input function's local error state:

```
using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
use_facet<numget>(loc).get(*this, 0, *this, state, val);
```

In the above fragment, `loc` stands for the private member of the `basic_ios` class.

NOTE 1 The first argument provides an object of the `istreambuf_iterator` class which is an iterator pointed to an input stream. It bypasses istreams and uses streambufs directly.

Class `locale` relies on this type as its interface to `istream`, so that it does not need to depend directly on `istream`.

```
basic_istream& operator>>(short& val);
```

The conversion occurs as if performed by the following code fragment (using the same notation as for the preceding code fragment):

```
using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
long lval;
use_facet<numget>(loc).get(*this, 0, *this, state, lval);
```

²⁸³) The `sentry` constructor and destructor can also perform additional implementation-dependent operations.

```

    if (lval < numeric_limits<short>::min()) {
        state |= ios_base::failbit;
        val = numeric_limits<short>::min();
    } else if (numeric_limits<short>::max() < lval) {
        state |= ios_base::failbit;
        val = numeric_limits<short>::max();
    } else
        val = static_cast<short>(lval);

basic_istream& operator>>(int& val);

```

The conversion occurs as if performed by the following code fragment (using the same notation as for the preceding code fragment):

```

    using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
    long lval;
    use_facet<numget>(loc).get(*this, 0, *this, state, lval);
    if (lval < numeric_limits<int>::min()) {
        state |= ios_base::failbit;
        val = numeric_limits<int>::min();
    } else if (numeric_limits<int>::max() < lval) {
        state |= ios_base::failbit;
        val = numeric_limits<int>::max();
    } else
        val = static_cast<int>(lval);

basic_istream& operator>>(extended-floating-point-type& val);

```

If the floating-point conversion rank of *extended-floating-point-type* is not less than or equal to that of `long double`, then an invocation of the operator function is conditionally supported with implementation-defined semantics.

Otherwise, let FP be a standard floating-point type:

- if the floating-point conversion rank of *extended-floating-point-type* is less than or equal to that of `float`, then FP is `float`,
- otherwise, if the floating-point conversion rank of *extended-floating-point-type* is less than or equal to that of `double`, then FP is `double`,
- otherwise, FP is `long double`.

The conversion occurs as if performed by the following code fragment (using the same notation as for the preceding code fragment):

```

    using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
    FP fval;
    use_facet<numget>(loc).get(*this, 0, *this, state, fval);
    if (fval < -numeric_limits<extended-floating-point-type>::max()) {
        state |= ios_base::failbit;
        val = -numeric_limits<extended-floating-point-type>::max();
    } else if (numeric_limits<extended-floating-point-type>::max() < fval) {
        state |= ios_base::failbit;
        val = numeric_limits<extended-floating-point-type>::max();
    } else {
        val = static_cast<extended-floating-point-type>(fval);
    }

```

NOTE 2 When the extended floating-point type has a floating-point conversion rank that is not equal to the rank of any standard floating-point type, then double rounding during the conversion can result in inaccurate results. `from_chars` can be used in situations where maximum accuracy is important.

31.7.5.3.3 `basic_istream::operator>>`

[istream.extractors]

```
basic_istream& operator>>(basic_istream& (*pf)(basic_istream&));
```

Effects: None. This extractor does not behave as a formatted input function (as described in 31.7.5.3.1).

Returns: `pf(*this)`.²⁸⁴

²⁸⁴ See, for example, the function signature `ws(basic_istream&)` (31.7.5.5).

```
basic_istream& operator>>(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&));
```

Effects: Calls `pf(*this)`. This extractor does not behave as a formatted input function (as described in 31.7.5.3.1).

Returns: `*this`.

```
basic_istream& operator>>(ios_base& (*pf)(ios_base&));
```

Effects: Calls `pf(*this)`.²⁸⁵ This extractor does not behave as a formatted input function (as described in 31.7.5.3.1).

Returns: `*this`.

```
template<class charT, class traits, size_t N>
```

```
    basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& in, charT (&s)[N]);
```

```
template<class traits, size_t N>
```

```
    basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, unsigned char (&s)[N]);
```

```
template<class traits, size_t N>
```

```
    basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, signed char (&s)[N]);
```

Effects: Behaves like a formatted input member (as described in 31.7.5.3.1) of `in`. After a `sentry` object is constructed, `operator>>` extracts characters and stores them into `s`. If `width()` is greater than zero, `n` is `min(size_t(width()), N)`. Otherwise `n` is `N`. `n` is the maximum number of characters stored.

Characters are extracted and stored until any of the following occurs:

- `n-1` characters are stored;
- end of file occurs on the input sequence;
- letting `ct` be `use_facet<ctype<charT>>(in.getloc())`, `ct.is(ct.space, c)` is true.

`operator>>` then stores a null byte (`charT()`) in the next position, which may be the first position if no characters were extracted. `operator>>` then calls `width(0)`.

If the function extracted no characters, `ios_base::failbit` is set in the input function's local error state before `setstate` is called.

Returns: `in`.

```
template<class charT, class traits>
```

```
    basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& in, charT& c);
```

```
template<class traits>
```

```
    basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, unsigned char& c);
```

```
template<class traits>
```

```
    basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, signed char& c);
```

Effects: Behaves like a formatted input member (as described in 31.7.5.3.1) of `in`. A character is extracted from `in`, if one is available, and stored in `c`. Otherwise, `ios_base::failbit` is set in the input function's local error state before `setstate` is called.

Returns: `in`.

```
basic_istream& operator>>(basic_streambuf<charT, traits>* sb);
```

Effects: Behaves as an unformatted input function (31.7.5.4). If `sb` is null, calls `setstate(fail-bit)`, which may throw `ios_base::failure` (31.5.4.4). After a `sentry` object is constructed, extracts characters from `*this` and inserts them in the output sequence controlled by `sb`. Characters are extracted and inserted until any of the following occurs:

- end-of-file occurs on the input sequence;
- inserting in the output sequence fails (in which case the character to be inserted is not extracted);
- an exception occurs (in which case the exception is caught).

If the function inserts no characters, `ios_base::failbit` is set in the input function's local error state before `setstate` is called.

Returns: `*this`.

²⁸⁵ See, for example, the function signature `dec(ios_base&)` (31.5.5.3).

31.7.5.4 Unformatted input functions

[istream.unformatted]

Each unformatted input function begins execution by constructing an object of type `ios_base::iostate`, termed the local error state, and initializing it to `ios_base::goodbit`. It then creates an object of class `sentry` with the default argument `noskipws` (second) argument `true`. If the `sentry` object returns `true`, when converted to a value of type `bool`, the function endeavors to obtain the requested input. Otherwise, if the `sentry` constructor exits by throwing an exception or if the `sentry` object produces `false`, when converted to a value of type `bool`, the function returns without attempting to obtain any input. In either case the number of extracted characters is set to 0; unformatted input functions taking a character array of nonzero size as an argument shall also store a null character (using `charT()`) in the first location of the array. If `rdbuf()->sgetc()` or `rdbuf()->sgetpc()` returns `traits::eof()`, then `ios_base::eofbit` is set in the local error state and the input function stops trying to obtain the requested input. If an exception is thrown during input then `ios_base::badbit` is set in the local error state, `*this`'s error state is set to the local error state, and the exception is rethrown if `(exceptions() & badbit) != 0`. If no exception has been thrown it stores the number of characters extracted in a member object. After extraction is done, the input function calls `setstate`, which sets `*this`'s error state to the local error state, and may throw an exception. In any event the `sentry` object is destroyed before leaving the unformatted input function.

```
streamsize gcount() const;
```

Effects: None. This member function does not behave as an unformatted input function (as described above).

Returns: The number of characters extracted by the last unformatted input member function called for the object. If the number cannot be represented, returns `numeric_limits<streamsize>::max()`.

```
int_type get();
```

Effects: Behaves as an unformatted input function (as described above). After constructing a `sentry` object, extracts a character `c`, if one is available. Otherwise, `ios_base::failbit` is set in the input function's local error state before `setstate` is called.

Returns: `c` if available, otherwise `traits::eof()`.

```
basic_istream& get(char_type& c);
```

Effects: Behaves as an unformatted input function (as described above). After constructing a `sentry` object, extracts a character, if one is available, and assigns it to `c`.²⁸⁶ Otherwise, `ios_base::failbit` is set in the input function's local error state before `setstate` is called.

Returns: `*this`.

```
basic_istream& get(char_type* s, streamsize n, char_type delim);
```

Effects: Behaves as an unformatted input function (as described above). After constructing a `sentry` object, extracts characters and stores them into successive locations of an array whose first element is designated by `s`.²⁸⁷ Characters are extracted and stored until any of the following occurs:

- `n` is less than one or `n - 1` characters are stored;
- end-of-file occurs on the input sequence;
- `traits::eq(c, delim)` for the next available input character `c` (in which case `c` is not extracted).

If the function stores no characters, `ios_base::failbit` is set in the input function's local error state before `setstate` is called. In any case, if `n` is greater than zero it then stores a null character into the next successive location of the array.

Returns: `*this`.

```
basic_istream& get(char_type* s, streamsize n);
```

Effects: Calls `get(s, n, widen('\n'))`.

Returns: Value returned by the call.

²⁸⁶) Note that this function is not overloaded on types `signed char` and `unsigned char`.

²⁸⁷) Note that this function is not overloaded on types `signed char` and `unsigned char`.

```
basic_istream& get(basic_streambuf<char_type, traits>& sb, char_type delim);
```

Effects: Behaves as an unformatted input function (as described above). After constructing a **sentry** object, extracts characters and inserts them in the output sequence controlled by **sb**. Characters are extracted and inserted until any of the following occurs:

- end-of-file occurs on the input sequence;
- inserting in the output sequence fails (in which case the character to be inserted is not extracted);
- **traits::eq(c, delim)** for the next available input character **c** (in which case **c** is not extracted);
- an exception occurs (in which case, the exception is caught but not rethrown).

If the function inserts no characters, **ios_base::failbit** is set in the input function's local error state before **setstate** is called.

Returns: ***this**.

```
basic_istream& get(basic_streambuf<char_type, traits>& sb);
```

Effects: Calls **get(sb, widen('\n'))**.

Returns: Value returned by the call.

```
basic_istream& getline(char_type* s, streamsize n, char_type delim);
```

Effects: Behaves as an unformatted input function (as described above). After constructing a **sentry** object, extracts characters and stores them into successive locations of an array whose first element is designated by **s**.²⁸⁸ Characters are extracted and stored until one of the following occurs:

1. end-of-file occurs on the input sequence;
2. **traits::eq(c, delim)** for the next available input character **c** (in which case the input character is extracted but not stored);²⁸⁹
3. **n** is less than one or **n - 1** characters are stored (in which case the function calls **setstate(failbit)**).

These conditions are tested in the order shown.²⁹⁰

If the function extracts no characters, **ios_base::failbit** is set in the input function's local error state before **setstate** is called.²⁹¹

In any case, if **n** is greater than zero, it then stores a null character (using **charT()**) into the next successive location of the array.

Returns: ***this**.

EXAMPLE

```
#include <iostream>

int main() {
    using namespace std;
    const int line_buffer_size = 100;

    char buffer[line_buffer_size];
    int line_number = 0;
    while (cin.getline(buffer, line_buffer_size, '\n') || cin.gcount()) {
        int count = cin.gcount();
        if (cin.eof())
            cout << "Partial final line";    // cin.fail() is false
        else if (cin.fail()) {
            cout << "Partial long line";
            cin.clear(cin.rdstate() & ~ios_base::failbit);
        } else {
            count--;
            // Don't include newline in count
        }
    }
}
```

²⁸⁸) Note that this function is not overloaded on types **signed char** and **unsigned char**.

²⁸⁹) Since the final input character is “extracted”, it is counted in the **gcount()**, even though it is not stored.

²⁹⁰) This allows an input line which exactly fills the buffer, without setting **failbit**. This is different behavior than the historical AT&T implementation.

²⁹¹) This implies an empty input line will not cause **failbit** to be set.

```

        cout << "Line " << ++line_number;
    }
    cout << " (" << count << " chars): " << buffer << endl;
}
}

```

`basic_istream& getline(char_type* s, streamsize n);`

Returns: `getline(s, n, widen('\n'))`

`basic_istream& ignore(streamsize n = 1, int_type delim = traits::eof());`

Effects: Behaves as an unformatted input function (as described above). After constructing a `sentry` object, extracts characters and discards them. Characters are extracted until any of the following occurs:

- `n != numeric_limits<streamsize>::max()` (17.3.5) and `n` characters have been extracted so far
- end-of-file occurs on the input sequence (in which case the function calls `setstate(eofbit)`, which may throw `ios_base::failure` (31.5.4.4));
- `traits::eq_int_type(traits::to_int_type(c), delim)` for the next available input character `c` (in which case `c` is extracted).

NOTE 1 The last condition will never occur if `traits::eq_int_type(delim, traits::eof())`.

Returns: `*this`.

`int_type peek();`

Effects: Behaves as an unformatted input function (as described above). After constructing a `sentry` object, reads but does not extract the current input character.

Returns: `traits::eof()` if `good()` is false. Otherwise, returns `rdbuf()->sgetc()`.

`basic_istream& read(char_type* s, streamsize n);`

Effects: Behaves as an unformatted input function (as described above). After constructing a `sentry` object, if `!good()` calls `setstate(failbit)` which may throw an exception, and return. Otherwise extracts characters and stores them into successive locations of an array whose first element is designated by `s`.²⁹² Characters are extracted and stored until either of the following occurs:

- `n` characters are stored;
- end-of-file occurs on the input sequence (in which case the function calls `setstate(failbit | eofbit)`, which may throw `ios_base::failure` (31.5.4.4)).

Returns: `*this`.

`streamsize readsome(char_type* s, streamsize n);`

Effects: Behaves as an unformatted input function (as described above). After constructing a `sentry` object, if `!good()` calls `setstate(failbit)` which may throw an exception, and return. Otherwise extracts characters and stores them into successive locations of an array whose first element is designated by `s`. If `rdbuf()->in_avail() == -1`, calls `setstate(eofbit)` (which may throw `ios_base::failure` (31.5.4.4)), and extracts no characters;

- If `rdbuf()->in_avail() == 0`, extracts no characters
- If `rdbuf()->in_avail() > 0`, extracts `min(rdbuf()->in_avail(), n)`.

Returns: The number of characters extracted.

`basic_istream& putback(char_type c);`

Effects: Behaves as an unformatted input function (as described above), except that the function first clears `eofbit`. After constructing a `sentry` object, if `!good()` calls `setstate(failbit)` which may throw an exception, and return. If `rdbuf()` is not null, calls `rdbuf()->sputbackc(c)`. If `rdbuf()` is null, or if `sputbackc` returns `traits::eof()`, calls `setstate(badbit)` (which may throw `ios_base::failure` (31.5.4.4)).

²⁹²) Note that this function is not overloaded on types `signed char` and `unsigned char`.

NOTE 2 This function extracts no characters, so the value returned by the next call to `gcount()` is 0.

*Returns: *this.*

`basic_istream& unget();`

Effects: Behaves as an unformatted input function (as described above), except that the function first clears `eofbit`. After constructing a `sentry` object, if `!good()` calls `setstate(failbit)` which may throw an exception, and return. If `rdbuf()` is not null, calls `rdbuf()->sungetc()`. If `rdbuf()` is null, or if `sungetc` returns `traits::eof()`, calls `setstate(badbit)` (which may throw `ios_base::failure` (31.5.4.4)).

NOTE 3 This function extracts no characters, so the value returned by the next call to `gcount()` is 0.

*Returns: *this.*

`int sync();`

Effects: Behaves as an unformatted input function (as described above), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to `gcount()`. After constructing a `sentry` object, if `rdbuf()` is a null pointer, returns -1. Otherwise, calls `rdbuf()->pubsync()` and, if that function returns -1 calls `setstate(badbit)` (which may throw `ios_base::failure` (31.5.4.4), and returns -1. Otherwise, returns zero.

`pos_type tellg();`

Effects: Behaves as an unformatted input function (as described above), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to `gcount()`.

Returns: After constructing a `sentry` object, if `fail() != false`, returns `pos_type(-1)` to indicate failure. Otherwise, returns `rdbuf()->pubseekoff(0, cur, in)`.

`basic_istream& seekg(pos_type pos);`

Effects: Behaves as an unformatted input function (as described above), except that the function first clears `eofbit`, it does not count the number of characters extracted, and it does not affect the value returned by subsequent calls to `gcount()`. After constructing a `sentry` object, if `fail() != true`, executes `rdbuf()->pubseekpos(pos, ios_base::in)`. In case of failure, the function calls `setstate(failbit)` (which may throw `ios_base::failure`).

*Returns: *this.*

`basic_istream& seekg(off_type off, ios_base::seekdir dir);`

Effects: Behaves as an unformatted input function (as described above), except that the function first clears `eofbit`, does not count the number of characters extracted, and does not affect the value returned by subsequent calls to `gcount()`. After constructing a `sentry` object, if `fail() != true`, executes `rdbuf()->pubseekoff(off, dir, ios_base::in)`. In case of failure, the function calls `setstate(failbit)` (which may throw `ios_base::failure`).

*Returns: *this.*

31.7.5.5 Standard `basic_istream` manipulators

[istream.manip]

Each instantiation of the function template specified in this subclause is a designated addressable function (16.4.5.2.1).

`template<class charT, class traits>`

`basic_istream<charT, traits>& ws(basic_istream<charT, traits>& is);`

Effects: Behaves as an unformatted input function (31.7.5.4), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to `is.gcount()`. After constructing a `sentry` object extracts characters as long as the next available character `c` is whitespace or until there are no more characters in the sequence. Whitespace characters are distinguished with the same criterion as used by `sentry::sentry` (31.7.5.2.4). If `ws` stops extracting characters because there are no more available it sets `eofbit`, but not `failbit`.

Returns: is.

31.7.5.6 Rvalue stream extraction

[istream.rvalue]

```
template<class Istream, class T>
Istream&& operator>>(Istream&& is, T&& x);
```

Constraints: The expression `is >> std::forward<T>(x)` is well-formed when treated as an unevaluated operand (7.2.3) and `Istream` is publicly and unambiguously derived from `ios_base`.

Effects: Equivalent to:

```
is >> std::forward<T>(x);
return std::move(is);
```

31.7.5.7 Class template `basic_iostream`

[iostreamclass]

31.7.5.7.1 General

[iostreamclass.general]

```
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_iostream
    : public basic_istream<charT, traits>,
      public basic_ostream<charT, traits> {
    public:
        using char_type      = charT;
        using int_type        = typename traits::int_type;
        using pos_type        = typename traits::pos_type;
        using off_type        = typename traits::off_type;
        using traits_type      = traits;

        // 31.7.5.7.2, constructor
        explicit basic_iostream(basic_streambuf<charT, traits>* sb);

        // 31.7.5.7.3, destructor
        virtual ~basic_iostream();

    protected:
        // 31.7.5.7.2, constructor
        basic_iostream(const basic_iostream&) = delete;
        basic_iostream(basic_iostream&& rhs);

        // 31.7.5.7.4, assignment and swap
        basic_iostream& operator=(const basic_iostream&) = delete;
        basic_iostream& operator=(basic_iostream&& rhs);
        void swap(basic_iostream& rhs);
    };
}
```

The class template `basic_iostream` inherits a number of functions that allow reading input and writing output to sequences controlled by a stream buffer.

31.7.5.7.2 Constructors

[iostream.cons]

```
explicit basic_iostream(basic_streambuf<charT, traits>* sb);
```

Effects: Initializes the base class subobjects with `basic_istream<charT, traits>(sb)` (31.7.5.2) and `basic_ostream<charT, traits>(sb)` (31.7.6.2).

Postconditions: `rddbuf() == sb` and `gcount() == 0`.

```
basic_iostream(basic_iostream&& rhs);
```

Effects: Move constructs from the rvalue `rhs` by constructing the `basic_istream` base class with `std::move(rhs)`.

31.7.5.7.3 Destructor

[iostream.dest]

```
virtual ~basic_iostream();
```

Remarks: Does not perform any operations on `rddbuf()`.

31.7.5.7.4 Assignment and swap

[iostream.assign]

```
basic_ostream& operator=(basic_ostream&& rhs);
```

Effects: Equivalent to: `swap(rhs)`.

```
void swap(basic_ostream& rhs);
```

Effects: Calls `basic_istream<charT, traits>::swap(rhs)`.

31.7.6 Output streams

[output.streams]

31.7.6.1 General

[output.streams.general]

The header `<ostream>` defines a class template and several function templates that control output to a stream buffer, along with a function template that inserts into stream rvalues.

31.7.6.2 Class template `basic_ostream`

[ostream]

31.7.6.2.1 General

[ostream.general]

When a function has a parameter type *extended-floating-point-type*, the implementation provides overloads for all cv-unqualified extended floating-point types (6.8.2).

```
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_ostream : virtual public basic_ios<charT, traits> {
    public:
        // types (inherited from basic_ios (31.5.4))
        using char_type    = charT;
        using int_type      = typename traits::int_type;
        using pos_type      = typename traits::pos_type;
        using off_type      = typename traits::off_type;
        using traits_type   = traits;

        // 31.7.6.2.2, constructor/destructor
        explicit basic_ostream(basic_streambuf<char_type, traits>* sb);
        virtual ~basic_ostream();

        // 31.7.6.2.4, prefix/suffix
        class sentry;

        // 31.7.6.3, formatted output
        basic_ostream& operator<<(basic_ostream& (*pf)(basic_ostream&));
        basic_ostream& operator<<(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&));
        basic_ostream& operator<<(ios_base& (*pf)(ios_base&));

        basic_ostream& operator<<(bool n);
        basic_ostream& operator<<(short n);
        basic_ostream& operator<<(unsigned short n);
        basic_ostream& operator<<(int n);
        basic_ostream& operator<<(unsigned int n);
        basic_ostream& operator<<(long n);
        basic_ostream& operator<<(unsigned long n);
        basic_ostream& operator<<(long long n);
        basic_ostream& operator<<(unsigned long long n);
        basic_ostream& operator<<(float f);
        basic_ostream& operator<<(double f);
        basic_ostream& operator<<(long double f);
        basic_ostream& operator<<(extended-floating-point-type f);

        basic_ostream& operator<<(const void* p);
        basic_ostream& operator<<(const volatile void* p);
        basic_ostream& operator<<(nullptr_t);
        basic_ostream& operator<<(basic_streambuf<char_type, traits>* sb);

        // 31.7.6.4, unformatted output
        basic_ostream& put(char_type c);
        basic_ostream& write(const char_type* s, streamsize n);
```

```

basic_ostream& flush();

// 31.7.6.2.5, seeks
pos_type tellp();
basic_ostream& seekp(pos_type);
basic_ostream& seekp(off_type, ios_base::seekdir);

```

The class template `basic_ostream` defines a number of member function signatures that assist in formatting and writing output to output sequences controlled by a stream buffer.

Two groups of member function signatures share common properties: the *formatted output functions* (or *inserters*) and the *unformatted output functions*. Both groups of output functions generate (or *insert*) output *characters* by actions equivalent to calling `rddbuf() -> sputc(int_type)`. They may use other public members of `basic_ostream` except that they shall not invoke any virtual members of `rddbuf()` except `overflow()`, `xspn()`, and `sync()`.

If one of these called functions throws an exception, then unless explicitly noted otherwise the output function sets `badbit` in the error state. If `badbit` is set in `exceptions()`, the output function rethrows the exception without completing its actions, otherwise it does not throw anything and proceeds as if the called function had returned a failure indication.

NOTE The deleted overloads of `operator<<` prevent formatting characters as integers and strings as pointers.

31.7.6.2.2 Constructors

[ostream.cons]

```
explicit basic_ostream(basic_streambuf<charT, traits>* sb);
```

Effects: Initializes the base class subobject with `basic_ios<charT, traits>::init(sb)` (31.5.4.2).

Postconditions: `rddbuf() == sb`.

```
basic_ostream(basic_ostream&& rhs);
```

Effects: Move constructs from the rvalue `rhs`. This is accomplished by default constructing the base class and calling `basic_ios<charT, traits>::move(rhs)` to initialize the base class.

```
virtual ~basic_ostream();
```

Remarks: Does not perform any operations on `rddbuf()`.

31.7.6.2.3 Assignment and swap

[ostream.assign]

```
basic_ostream& operator=(basic_ostream&& rhs);
```

Effects: Equivalent to: `swap(rhs)`.

Returns: `*this`.

```
void swap(basic_ostream& rhs);
```

Effects: Calls `basic_ios<charT, traits>::swap(rhs)`.

31.7.6.2.4 Class `basic_ostream::sentry`

[ostream.sentry]

```

namespace std {
    template<class charT, class traits>
    class basic_ostream<charT, traits>::sentry {
        bool ok_;           // exposition only
    };
}

```

```

public:
    explicit sentry(basic_ostream& os);
    ~sentry();
    explicit operator bool() const { return ok_; }

    sentry(const sentry&) = delete;
    sentry& operator=(const sentry&) = delete;
};
}

```

The class `sentry` defines a class that is responsible for doing exception safe prefix and suffix operations.

```
explicit sentry(basic_ostream& os);
```

If `os.good()` is nonzero, prepares for formatted or unformatted output. If `os.tie()` is not a null pointer, calls `os.tie()->flush()`.²⁹³

If, after any preparation is completed, `os.good()` is true, `ok_ == true` otherwise, `ok_ == false`. During preparation, the constructor may call `setstate(failbit)` (which may throw `ios_base::failure` (31.5.4.4)).²⁹⁴

```
~sentry();
```

If `(os.flags() & ios_base::unitbuf) && !uncaught_exceptions() && os.good()` is true, calls `os.rdbuf()->pubsync()`. If that function returns `-1`, sets `badbit` in `os.rdstate()` without propagating an exception.

```
explicit operator bool() const;
```

Effects: Returns `ok_`.

31.7.6.2.5 Seek members

[ostream.seek]

Each seek member function begins execution by constructing an object of class `sentry`. It returns by destroying the `sentry` object.

```
pos_type tellp();
```

Returns: If `fail() != false`, returns `pos_type(-1)` to indicate failure. Otherwise, returns `rdbuf()->pubseekoff(0, cur, out)`.

```
basic_ostream& seekp(pos_type pos);
```

Effects: If `fail() != true`, executes `rdbuf()->pubseekpos(pos, ios_base::out)`. In case of failure, the function calls `setstate(failbit)` (which may throw `ios_base::failure`).

Returns: `*this`.

```
basic_ostream& seekp(off_type off, ios_base::seekdir dir);
```

Effects: If `fail() != true`, executes `rdbuf()->pubseekoff(off, dir, ios_base::out)`. In case of failure, the function calls `setstate(failbit)` (which may throw `ios_base::failure`).

Returns: `*this`.

31.7.6.3 Formatted output functions

[ostream.formatted]

31.7.6.3.1 Common requirements

[ostream.formatted.reqmts]

Each formatted output function begins execution by constructing an object of class `sentry`. If that object returns `true` when converted to a value of type `bool`, the function endeavors to generate the requested output. If the generation fails, then the formatted output function does `setstate(ios_base::failbit)`, which can throw an exception. If an exception is thrown during output, then `ios_base::badbit` is set²⁹⁵ in `*this`'s error state. If `(exceptions() & badbit) != 0` then the exception is rethrown. Whether or not an exception is thrown, the `sentry` object is destroyed before leaving the formatted output function. If no exception is thrown, the result of the formatted output function is `*this`.

²⁹³) The call `os.tie()->flush()` does not necessarily occur if the function can determine that no synchronization is necessary.

²⁹⁴) The `sentry` constructor and destructor can also perform additional implementation-dependent operations.

²⁹⁵) This is done without causing an `ios_base::failure` to be thrown.

The descriptions of the individual formatted output functions describe how they perform output and do not mention the `sentry` object.

If a formatted output function of a stream `os` determines padding, it does so as follows. Given a `charT` character sequence `seq` where `charT` is the character type of the stream, if the length of `seq` is less than `os.width()`, then enough copies of `os.fill()` are added to this sequence as necessary to pad to a width of `os.width()` characters. If `(os.flags() & ios_base::adjustfield) == ios_base::left` is `true`, the fill characters are placed after the character sequence; otherwise, they are placed before the character sequence.

31.7.6.3.2 Arithmetic inserters

[ostream.inserters.arithmetic]

```
basic_ostream& operator<<(bool val);
basic_ostream& operator<<(short val);
basic_ostream& operator<<(unsigned short val);
basic_ostream& operator<<(int val);
basic_ostream& operator<<(unsigned int val);
basic_ostream& operator<<(long val);
basic_ostream& operator<<(unsigned long val);
basic_ostream& operator<<(long long val);
basic_ostream& operator<<(unsigned long long val);
basic_ostream& operator<<(float val);
basic_ostream& operator<<(double val);
basic_ostream& operator<<(long double val);
basic_ostream& operator<<(const void* val);
```

Effects: The classes `num_get<>` and `num_put<>` handle locale-dependent numeric formatting and parsing. These inserter functions use the imbued `locale` value to perform numeric formatting. When `val` is of type `bool`, `long`, `unsigned long`, `long long`, `unsigned long long`, `double`, `long double`, or `const void*`, the formatting conversion occurs as if it performed the following code fragment:

```
bool failed = use_facet<
    num_put<charT, ostreambuf_iterator<charT, traits>>
    >(getloc()).put(*this, *this, fill(), val).failed();
```

When `val` is of type `short` the formatting conversion occurs as if it performed the following code fragment:

```
ios_base::fmtflags baseflags = ios_base::flags() & ios_base::basefield;
bool failed = use_facet<
    num_put<charT, ostreambuf_iterator<charT, traits>>
    >(getloc()).put(*this, *this, fill(),
        baseflags == ios_base::oct || baseflags == ios_base::hex
        ? static_cast<long>(static_cast<unsigned short>(val))
        : static_cast<long>(val)).failed();
```

When `val` is of type `int` the formatting conversion occurs as if it performed the following code fragment:

```
ios_base::fmtflags baseflags = ios_base::flags() & ios_base::basefield;
bool failed = use_facet<
    num_put<charT, ostreambuf_iterator<charT, traits>>
    >(getloc()).put(*this, *this, fill(),
        baseflags == ios_base::oct || baseflags == ios_base::hex
        ? static_cast<long>(static_cast<unsigned int>(val))
        : static_cast<long>(val)).failed();
```

When `val` is of type `unsigned short` or `unsigned int` the formatting conversion occurs as if it performed the following code fragment:

```
bool failed = use_facet<
    num_put<charT, ostreambuf_iterator<charT, traits>>
    >(getloc()).put(*this, *this, fill(),
        static_cast<unsigned long>(val)).failed();
```

When `val` is of type `float` the formatting conversion occurs as if it performed the following code fragment:

```
bool failed = use_facet<
    num_put<charT, ostreambuf_iterator<charT, traits>>
    >(getloc()).put(*this, *this, fill(),
        static_cast<double>(val)).failed();
```

The first argument provides an object of the `ostreambuf_iterator<>` class which is an iterator for class `basic_ostream<>`. It bypasses `ostreams` and uses `streambufs` directly. Class `locale` relies on these types as its interface to `iostreams`, since for flexibility it has been abstracted away from direct dependence on `ostream`. The second parameter is a reference to the base class subobject of type `ios_base`. It provides formatting specifications such as field width, and a locale from which to obtain other facets. If `failed` is `true` then does `setstate(badbit)`, which may throw an exception, and returns.

Returns: `*this`.

```
basic_ostream& operator<<(const volatile void* p);
```

Effects: Equivalent to: `return operator<<(const_cast<const void*>(p));`

```
basic_ostream& operator<<(extended-floating-point-type val);
```

Effects: If the floating-point conversion rank of `extended-floating-point-type` is less than or equal to that of `double`, the formatting conversion occurs as if it performed the following code fragment:

```
bool failed = use_facet<
    num_put<charT, ostreambuf_iterator<charT, traits>>
    >(getloc()).put(*this, *this, fill(),
        static_cast<double>(val)).failed();
```

Otherwise, if the floating-point conversion rank of `extended-floating-point-type` is less than or equal to that of `long double`, the formatting conversion occurs as if it performed the following code fragment:

```
bool failed = use_facet<
    num_put<charT, ostreambuf_iterator<charT, traits>>
    >(getloc()).put(*this, *this, fill(),
        static_cast<long double>(val)).failed();
```

Otherwise, an invocation of the operator function is conditionally supported with implementation-defined semantics.

If `failed` is `true` then does `setstate(badbit)`, which may throw an exception, and returns.

Returns: `*this`.

31.7.6.3.3 `basic_ostream::operator<<` [ostream.inserters]

```
basic_ostream& operator<<(basic_ostream& (*pf)(basic_ostream&));
```

Effects: None. Does not behave as a formatted output function (as described in 31.7.6.3.1).

Returns: `pf(*this)`.²⁹⁶

```
basic_ostream& operator<<(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&));
```

Effects: Calls `pf(*this)`. This inserter does not behave as a formatted output function (as described in 31.7.6.3.1).

Returns: `*this`.²⁹⁷

```
basic_ostream& operator<<(ios_base& (*pf)(ios_base&));
```

Effects: Calls `pf(*this)`. This inserter does not behave as a formatted output function (as described in 31.7.6.3.1).

Returns: `*this`.

```
basic_ostream& operator<<(basic_streambuf<charT, traits>* sb);
```

Effects: Behaves as an unformatted output function (31.7.6.4). After the `sentry` object is constructed, if `sb` is null calls `setstate(badbit)` (which may throw `ios_base::failure`).

²⁹⁶ See, for example, the function signature `endl(basic_ostream&)` (31.7.6.5).

²⁹⁷ See, for example, the function signature `dec(ios_base&)` (31.5.5.3).

Gets characters from **sb** and inserts them in ***this**. Characters are read from **sb** and inserted until any of the following occurs:

- end-of-file occurs on the input sequence;
- inserting in the output sequence fails (in which case the character to be inserted is not extracted);
- an exception occurs while getting a character from **sb**.

If the function inserts no characters, it calls `setstate(failbit)` (which may throw `ios_base::failure` (31.5.4.4)). If an exception was thrown while extracting a character, the function sets `failbit` in the error state, and if `failbit` is set in `exceptions()` the caught exception is rethrown.

Returns: ***this**.

```
basic_ostream& operator<<(nullptr_t);
```

Effects: Equivalent to:

```
return *this << s;
```

where **s** is an implementation-defined NTCTS (3.34).

31.7.6.3.4 Character inserter function templates

[ostream.insetters.character]

```
template<class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, charT c);
template<class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, char c);
// specialization
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, char c);
// signed and unsigned
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, signed char c);
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, unsigned char c);
```

Effects: Behaves as a formatted output function (31.7.6.3.1) of **out**. Constructs a character sequence **seq**. If **c** has type `char` and the character type of the stream is not `char`, then **seq** consists of `out.widen(c)`; otherwise **seq** consists of **c**. Determines padding for **seq** as described in 31.7.6.3.1. Inserts **seq** into **out**. Calls `os.width(0)`.

Returns: **out**.

```
template<class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, const charT* s);
template<class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, const char* s);
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, const char* s);
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, const signed char* s);
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out,
                                         const unsigned char* s);
```

Preconditions: **s** is not a null pointer.

Effects: Behaves like a formatted inserter (as described in 31.7.6.3.1) of **out**. Creates a character sequence **seq** of **n** characters starting at **s**, each widened using `out.widen()` (31.5.4.3), where **n** is the number that would be computed as if by:

- `traits::length(s)` for the overload where the first argument is of type `basic_ostream<charT, traits>&` and the second is of type `const charT*`, and also for the overload where the first argument is of type `basic_ostream<char, traits>&` and the second is of type `const char*`,
- `char_traits<char>::length(s)` for the overload where the first argument is of type `basic_ostream<charT, traits>&` and the second is of type `const char*`,
- `traits::length(reinterpret_cast<const char*>(s))` for the other two overloads.

Determines padding for `seq` as described in 31.7.6.3.1. Inserts `seq` into `out`. Calls `width(0)`.

Returns: `out`.

31.7.6.3.5 Print

[ostream.formatted.print]

```
template<class... Args>
void print(ostream& os, format_string<Args...> fmt, Args&&... args);
```

Effects: If the ordinary literal encoding (5.3) is UTF-8, equivalent to:

```
vprint_unicode(os, fmt.str, make_format_args(std::forward<Args>(args)...));
```

Otherwise, equivalent to:

```
vprint_nonunicode(os, fmt.str, make_format_args(std::forward<Args>(args)...));
```

```
template<class... Args>
void println(ostream& os, format_string<Args...> fmt, Args&&... args);
```

Effects: Equivalent to:

```
print(os, "{}\n", format(fmt, std::forward<Args>(args)...));
```

```
void vprint_unicode(ostream& os, string_view fmt, format_args args);
void vprint_nonunicode(ostream& os, string_view fmt, format_args args);
```

Effects: Behaves as a formatted output function (31.7.6.3.1) of `os`, except that:

- failure to generate output is reported as specified below, and
- any exception thrown by the call to `vformat` is propagated without regard to the value of `os.exceptions()` and without turning on `ios_base::badbit` in the error state of `os`.

After constructing a `sentry` object, the function initializes an automatic variable via

```
string out = vformat(os.getloc(), fmt, args);
```

If the function is `vprint_unicode` and `os` is a stream that refers to a terminal capable of displaying Unicode which is determined in an implementation-defined manner, writes `out` to the terminal using the native Unicode API; if `out` contains invalid code units, the behavior is undefined and implementations are encouraged to diagnose it. If the native Unicode API is used, the function flushes `os` before writing `out`. Otherwise (if `os` is not such a stream or the function is `vprint_nonunicode`), inserts the character sequence `[out.begin(), out.end())` into `os`. If writing to the terminal or inserting into `os` fails, calls `os.setstate(ios_base::badbit)` (which may throw `ios_base::failure`).

Recommended practice: For `vprint_unicode`, if invoking the native Unicode API requires transcoding, implementations should substitute invalid code units with U+FFFD REPLACEMENT CHARACTER per the Unicode Standard, Chapter 3.9 U+FFFD Substitution in Conversion.

31.7.6.4 Unformatted output functions

[ostream.unformatted]

Each unformatted output function begins execution by constructing an object of class `sentry`. If that object returns `true`, while converting to a value of type `bool`, the function endeavors to generate the requested output. If an exception is thrown during output, then `ios_base::badbit` is set²⁹⁸ in `*this`'s error state. If `(exceptions() & badbit) != 0` then the exception is rethrown. In any case, the unformatted output function ends by destroying the `sentry` object, then, if no exception was thrown, returning the value specified for the unformatted output function.

```
basic_ostream& put(char_type c);
```

Effects: Behaves as an unformatted output function (as described above). After constructing a `sentry` object, inserts the character `c`, if possible.²⁹⁹

Otherwise, calls `setstate(badbit)` (which may throw `ios_base::failure` (31.5.4.4)).

Returns: `*this`.

²⁹⁸) This is done without causing an `ios_base::failure` to be thrown.

²⁹⁹) Note that this function is not overloaded on types `signed char` and `unsigned char`.

```
basic_ostream& write(const char_type* s, streamsize n);
```

Effects: Behaves as an unformatted output function (as described above). After constructing a `sentry` object, obtains characters to insert from successive locations of an array whose first element is designated by `s`.³⁰⁰ Characters are inserted until either of the following occurs:

- `n` characters are inserted;
- inserting in the output sequence fails (in which case the function calls `setstate(badbit)`, which may throw `ios_base::failure` (31.5.4.4)).

Returns: `*this`.

```
basic_ostream& flush();
```

Effects: Behaves as an unformatted output function (as described above). If `rdbuf()` is not a null pointer, constructs a `sentry` object. If that object returns `true` when converted to a value of type `bool` the function calls `rdbuf()->pubsync()`. If that function returns `-1` calls `setstate(badbit)` (which may throw `ios_base::failure` (31.5.4.4)). Otherwise, if the `sentry` object returns `false`, does nothing.

Returns: `*this`.

31.7.6.5 Standard manipulators

[ostream.manip]

Each instantiation of any of the function templates specified in this subclause is a designated addressable function (16.4.5.2.1).

```
template<class charT, class traits>
```

```
basic_ostream<charT, traits>& endl(basic_ostream<charT, traits>& os);
```

Effects: Calls `os.put(os.widen('\n'))`, then `os.flush()`.

Returns: `os`.

```
template<class charT, class traits>
```

```
basic_ostream<charT, traits>& ends(basic_ostream<charT, traits>& os);
```

Effects: Inserts a null character into the output sequence: calls `os.put(charT())`.

Returns: `os`.

```
template<class charT, class traits>
```

```
basic_ostream<charT, traits>& flush(basic_ostream<charT, traits>& os);
```

Effects: Calls `os.flush()`.

Returns: `os`.

```
template<class charT, class traits>
```

```
basic_ostream<charT, traits>& emit_on_flush(basic_ostream<charT, traits>& os);
```

Effects: If `os.rdbuf()` is a `basic_syncbuf<charT, traits, Allocator>*`, called `buf` for the purpose of exposition, calls `buf->set_emit_on_sync(true)`. Otherwise this manipulator has no effect.

NOTE To work around the issue that the `Allocator` template argument cannot be deduced, implementations can introduce an intermediate base class to `basic_syncbuf` that manages its `emit_on_sync` flag.

Returns: `os`.

```
template<class charT, class traits>
```

```
basic_ostream<charT, traits>& noemit_on_flush(basic_ostream<charT, traits>& os);
```

Effects: If `os.rdbuf()` is a `basic_syncbuf<charT, traits, Allocator>*`, called `buf` for the purpose of exposition, calls `buf->set_emit_on_sync(false)`. Otherwise this manipulator has no effect.

Returns: `os`.

```
template<class charT, class traits>
```

```
basic_ostream<charT, traits>& flush_emit(basic_ostream<charT, traits>& os);
```

Effects: Calls `os.flush()`. Then, if `os.rdbuf()` is a `basic_syncbuf<charT, traits, Allocator>*`, called `buf` for the purpose of exposition, behaves as an unformatted output function (31.7.6.4)

³⁰⁰) Note that this function is not overloaded on types `signed char` and `unsigned char`.

of `os`. After constructing a `sentry` object, calls `buf->emit()`. If that call returns `false`, calls `os.setstate(ios_base::badbit)`.

Returns: `os`.

31.7.6.6 Rvalue stream insertion

[ostream.rvalue]

```
template<class Ostream, class T>
Ostream&& operator<<(Ostream&& os, const T& x);
```

Constraints: The expression `os << x` is well-formed when treated as an unevaluated operand and `Ostream` is publicly and unambiguously derived from `ios_base`.

Effects: As if by: `os << x`;

Returns: `std::move(os)`.

31.7.7 Standard manipulators

[std.manip]

The header `<iomanip>` defines several functions that support extractors and inserters that alter information maintained by class `ios_base` and its derived classes.

unspecified `resetiosflags(ios_base::fmtflags mask);`

Returns: An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>` then the expression `out << resetiosflags(mask)` behaves as if it called `f(out, mask)`, or if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> resetiosflags(mask)` behaves as if it called `f(in, mask)`, where the function `f` is defined as:³⁰¹

```
void f(ios_base& str, ios_base::fmtflags mask) {
    // reset specified flags
    str.setf(ios_base::fmtflags(0), mask);
}
```

The expression `out << resetiosflags(mask)` has type `basic_ostream<charT, traits>&` and value `out`. The expression `in >> resetiosflags(mask)` has type `basic_istream<charT, traits>&` and value `in`.

unspecified `setiosflags(ios_base::fmtflags mask);`

Returns: An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>` then the expression `out << setiosflags(mask)` behaves as if it called `f(out, mask)`, or if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> setiosflags(mask)` behaves as if it called `f(in, mask)`, where the function `f` is defined as:

```
void f(ios_base& str, ios_base::fmtflags mask) {
    // set specified flags
    str.setf(mask);
}
```

The expression `out << setiosflags(mask)` has type `basic_ostream<charT, traits>&` and value `out`. The expression `in >> setiosflags(mask)` has type `basic_istream<charT, traits>&` and value `in`.

unspecified `setbase(int base);`

Returns: An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>` then the expression `out << setbase(base)` behaves as if it called `f(out, base)`, or if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> setbase(base)` behaves as if it called `f(in, base)`, where the function `f` is defined as:

```
void f(ios_base& str, int base) {
    // set basefield
    str.setf(base == 8 ? ios_base::oct :
            base == 10 ? ios_base::dec :
            base == 16 ? ios_base::hex :
```

³⁰¹) The expression `cin >> resetiosflags(ios_base::skipws)` clears `ios_base::skipws` in the format flags stored in the `basic_istream<charT, traits>` object `cin` (the same as `cin >> noskipws`), and the expression `cout << resetiosflags(ios_base::showbase)` clears `ios_base::showbase` in the format flags stored in the `basic_ostream<charT, traits>` object `cout` (the same as `cout << noshowbase`).

```

        ios_base::fmtflags(0), ios_base::basefield);
    }

```

The expression `out << setbase(base)` has type `basic_ostream<charT, traits>&` and value `out`.
The expression `in >> setbase(base)` has type `basic_istream<charT, traits>&` and value `in`.

unspecified `setfill(char_type c);`

Returns: An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>` and `c` has type `charT` then the expression `out << setfill(c)` behaves as if it called `f(out, c)`, where the function `f` is defined as:

```

template<class charT, class traits>
void f(basic_ios<charT, traits>& str, charT c) {
    // set fill character
    str.fill(c);
}

```

The expression `out << setfill(c)` has type `basic_ostream<charT, traits>&` and value `out`.

unspecified `setprecision(int n);`

Returns: An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>` then the expression `out << setprecision(n)` behaves as if it called `f(out, n)`, or if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> setprecision(n)` behaves as if it called `f(in, n)`, where the function `f` is defined as:

```

void f(ios_base& str, int n) {
    // set precision
    str.precision(n);
}

```

The expression `out << setprecision(n)` has type `basic_ostream<charT, traits>&` and value `out`.
The expression `in >> setprecision(n)` has type `basic_istream<charT, traits>&` and value `in`.

unspecified `setw(int n);`

Returns: An object of unspecified type such that if `out` is an instance of `basic_ostream<charT, traits>` then the expression `out << setw(n)` behaves as if it called `f(out, n)`, or if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> setw(n)` behaves as if it called `f(in, n)`, where the function `f` is defined as:

```

void f(ios_base& str, int n) {
    // set width
    str.width(n);
}

```

The expression `out << setw(n)` has type `basic_ostream<charT, traits>&` and value `out`. The expression `in >> setw(n)` has type `basic_istream<charT, traits>&` and value `in`.

31.7.8 Extended manipulators

[ext.manip]

The header `<iomanip>` defines several functions that support extractors and inserters that allow for the parsing and formatting of sequences and values for money and time.

```
template<class moneyT> unspecified get_money(moneyT& mon, bool intl = false);
```

Mandates: The type `moneyT` is either `long double` or a specialization of the `basic_string` template (Clause 23).

Effects: The expression `in >> get_money(mon, intl)` described below behaves as a formatted input function (31.7.5.3.1).

Returns: An object of unspecified type such that if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> get_money(mon, intl)` behaves as if it called `f(in, mon, intl)`, where the function `f` is defined as:

```

template<class charT, class traits, class moneyT>
void f(basic_ios<charT, traits>& str, moneyT& mon, bool intl) {
    using Iter    = istreambuf_iterator<charT, traits>;
    using MoneyGet = money_get<charT, Iter>;
}

```

```

ios_base::iostate err = ios_base::goodbit;
const MoneyGet& mg = use_facet<MoneyGet>(str.getloc());

mg.get(Iter(str.rdbuf()), Iter(), intl, str, err, mon);

if (ios_base::goodbit != err)
    str.setstate(err);
}

```

The expression in `>> get_money(mon, intl)` has type `basic_istream<charT, traits>&` and value `in`.

```
template<class moneyT> unspecified put_money(const moneyT& mon, bool intl = false);
```

Mandates: The type `moneyT` is either `long double` or a specialization of the `basic_string` template (Clause 23).

Returns: An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>` then the expression `out << put_money(mon, intl)` behaves as a formatted output function (31.7.6.3.1) that calls `f(out, mon, intl)`, where the function `f` is defined as:

```

template<class charT, class traits, class moneyT>
void f(basic_ios<charT, traits>& str, const moneyT& mon, bool intl) {
    using Iter      = ostreambuf_iterator<charT, traits>;
    using MoneyPut  = money_put<charT, Iter>;

    const MoneyPut& mp = use_facet<MoneyPut>(str.getloc());
    const Iter end = mp.put(Iter(str.rdbuf()), intl, str, str.fill(), mon);

    if (end.failed())
        str.setstate(ios_base::badbit);
}

```

The expression `out << put_money(mon, intl)` has type `basic_ostream<charT, traits>&` and value `out`.

```
template<class charT> unspecified get_time(tm* tmb, const charT* fmt);
```

Preconditions: The argument `tmb` is a valid pointer to an object of type `tm`, and `[fmt, fmt + char_traits<charT>::length(fmt))` is a valid range.

Returns: An object of unspecified type such that if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> get_time(tmb, fmt)` behaves as if it called `f(in, tmb, fmt)`, where the function `f` is defined as:

```

template<class charT, class traits>
void f(basic_ios<charT, traits>& str, tm* tmb, const charT* fmt) {
    using Iter      = istreambuf_iterator<charT, traits>;
    using TimeGet   = time_get<charT, Iter>;

    ios_base::iostate err = ios_base::goodbit;
    const TimeGet& tg = use_facet<TimeGet>(str.getloc());

    tg.get(Iter(str.rdbuf()), Iter(), str, err, tmb,
          fmt, fmt + traits::length(fmt));

    if (err != ios_base::goodbit)
        str.setstate(err);
}

```

The expression in `>> get_time(tmb, fmt)` has type `basic_istream<charT, traits>&` and value `in`.

```
template<class charT> unspecified put_time(const tm* tmb, const charT* fmt);
```

Preconditions: The argument `tmb` is a valid pointer to an object of type `tm`, and `[fmt, fmt + char_traits<charT>::length(fmt))` is a valid range.

Returns: An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>` then the expression `out << put_time(tmb, fmt)` behaves as if it called `f(out, tmb, fmt)`, where the function `f` is defined as:

```
template<class charT, class traits>
void f(basic_ios<charT, traits>& str, const tm* tmb, const charT* fmt) {
    using Iter    = ostreambuf_iterator<charT, traits>;
    using TimePut = time_put<charT, Iter>;

    const TimePut& tp = use_facet<TimePut>(str.getloc());
    const Iter end = tp.put(Iter(str.rdbuf()), str, str.fill(), tmb,
        fmt, fmt + traits::length(fmt));

    if (end.failed())
        str.setstate(ios_base::badbit);
}
```

The expression `out << put_time(tmb, fmt)` has type `basic_ostream<charT, traits>&` and value `out`.

31.7.9 Quoted manipulators

[quoted.manip]

NOTE Quoted manipulators provide string insertion and extraction of quoted strings (for example, XML and CSV formats). Quoted manipulators are useful in ensuring that the content of a string with embedded spaces remains unchanged if inserted and then extracted via stream I/O.

```
template<class charT>
    unspecified quoted(const charT* s, charT delim = charT('\"'), charT escape = charT('\\'));
template<class charT, class traits, class Allocator>
    unspecified quoted(const basic_string<charT, traits, Allocator>& s,
        charT delim = charT('\"'), charT escape = charT('\\'));
template<class charT, class traits>
    unspecified quoted(basic_string_view<charT, traits> s,
        charT delim = charT('\"'), charT escape = charT('\\'));
```

Returns: An object of unspecified type such that if `out` is an instance of `basic_ostream` with member type `char_type` the same as `charT` and with member type `traits_type`, which in the second and third forms is the same as `traits`, then the expression `out << quoted(s, delim, escape)` behaves as a formatted output function (31.7.6.3.1) of `out`. This forms a character sequence `seq`, initially consisting of the following elements:

- `delim`.
- Each character in `s`. If the character to be output is equal to `escape` or `delim`, as determined by `traits_type::eq`, first output `escape`.
- `delim`.

Let `x` be the number of elements initially in `seq`. Then padding is determined for `seq` as described in 31.7.6.3.1, `seq` is inserted as if by calling `out.rdbuf()->sputn(seq, n)`, where `n` is the larger of `out.width()` and `x`, and `out.width(0)` is called. The expression `out << quoted(s, delim, escape)` has type `basic_ostream<charT, traits>&` and value `out`.

```
template<class charT, class traits, class Allocator>
    unspecified quoted(basic_string<charT, traits, Allocator>& s,
        charT delim = charT('\"'), charT escape = charT('\\'));
```

Returns: An object of unspecified type such that:

- If `in` is an instance of `basic_istream` with member types `char_type` and `traits_type` the same as `charT` and `traits`, respectively, then the expression `in >> quoted(s, delim, escape)` behaves as if it extracts the following characters from `in` using `operator>>(basic_istream<charT, traits>&, charT&)` (31.7.5.3.3) which may throw `ios_base::failure` (31.5.2.2.1):
 - If the first character extracted is equal to `delim`, as determined by `traits_type::eq`, then:
 - Turn off the `skipws` flag.
 - `s.clear()`

- Until an unescaped `delim` character is reached or `!in`, extract characters from `in` and append them to `s`, except that if an `escape` is reached, ignore it and append the next character to `s`.
- Discard the final `delim` character.
- Restore the `skipws` flag to its original value.
- Otherwise, `in >> s`.
- If `out` is an instance of `basic_ostream` with member types `char_type` and `traits_type` the same as `charT` and `traits`, respectively, then the expression `out << quoted(s, delim, escape)` behaves as specified for the `const basic_string<charT, traits, Allocator>&` overload of the `quoted` function.
- The expression `in >> quoted(s, delim, escape)` has type `basic_istream<charT, traits>&` and value `in`.
- The expression `out << quoted(s, delim, escape)` has type `basic_ostream<charT, traits>&` and value `out`.

31.7.10 Print functions

[print.fun]

```
template<class... Args>
void print(format_string<Args...> fmt, Args&&... args);
```

Effects: Equivalent to:

```
print(stdout, fmt, std::forward<Args>(args)...);
```

```
template<class... Args>
void print(FILE* stream, format_string<Args...> fmt, Args&&... args);
```

Effects: If the ordinary literal encoding (5.3) is UTF-8, equivalent to:

```
vprint_unicode(stream, fmt.str, make_format_args(std::forward<Args>(args)...));
```

Otherwise, equivalent to:

```
vprint_nonunicode(stream, fmt.str, make_format_args(std::forward<Args>(args)...));
```

```
template<class... Args>
void println(format_string<Args...> fmt, Args&&... args);
```

Effects: Equivalent to:

```
println(stdout, fmt, std::forward<Args>(args)...);
```

```
template<class... Args>
void println(FILE* stream, format_string<Args...> fmt, Args&&... args);
```

Effects: Equivalent to:

```
print(stream, "{}\n", format(fmt, std::forward<Args>(args)...));
```

```
void vprint_unicode(string_view fmt, format_args args);
```

Effects: Equivalent to:

```
vprint_unicode(stdout, fmt, args);
```

```
void vprint_unicode(FILE* stream, string_view fmt, format_args args);
```

Preconditions: `stream` is a valid pointer to an output C stream.

Effects: The function initializes an automatic variable via

```
string out = vformat(fmt, args);
```

If `stream` refers to a terminal capable of displaying Unicode, writes `out` to the terminal using the native Unicode API; if `out` contains invalid code units, the behavior is undefined and implementations are encouraged to diagnose it. Otherwise writes `out` to `stream` unchanged. If the native Unicode API is used, the function flushes `stream` before writing `out`.

NOTE 1 On POSIX and Windows, `stream` referring to a terminal means that, respectively, `isatty(fileno(stream))` and `GetConsoleMode(_get_osfhandle(_fileno(stream)), ...)` return nonzero.

NOTE 2 On Windows, the native Unicode API is `WriteConsoleW`.

Throws: Any exception thrown by the call to `vformat` (22.14.3). `system_error` if writing to the terminal or `stream` fails. May throw `bad_alloc`.

Recommended practice: If invoking the native Unicode API requires transcoding, implementations should substitute invalid code units with U+FFFD REPLACEMENT CHARACTER per the Unicode Standard, Chapter 3.9 U+FFFD Substitution in Conversion.

```
void vprint_nonunicode(string_view fmt, format_args args);
```

Effects: Equivalent to:

```
vprint_nonunicode(stdout, fmt, args);
```

```
void vprint_nonunicode(FILE* stream, string_view fmt, format_args args);
```

Preconditions: `stream` is a valid pointer to an output C stream.

Effects: Writes the result of `vformat(fmt, args)` to `stream`.

Throws: Any exception thrown by the call to `vformat` (22.14.3). `system_error` if writing to `stream` fails. May throw `bad_alloc`.

31.8 String-based streams

[string.streams]

31.8.1 Header <sstream> synopsis

[sstream.syn]

```
namespace std {
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
        class basic_stringbuf;

    template<class charT, class traits, class Allocator>
        void swap(basic_stringbuf<charT, traits, Allocator>& x,
                  basic_stringbuf<charT, traits, Allocator>& y) noexcept(noexcept(x.swap(y)));

    using stringbuf = basic_stringbuf<char>;
    using wstringbuf = basic_stringbuf<wchar_t>;

    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
        class basic_istreamstream;

    template<class charT, class traits, class Allocator>
        void swap(basic_istreamstream<charT, traits, Allocator>& x,
                  basic_istreamstream<charT, traits, Allocator>& y);

    using istringstream = basic_istreamstream<char>;
    using wistringstream = basic_istreamstream<wchar_t>;

    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
        class basic_ostreamstream;

    template<class charT, class traits, class Allocator>
        void swap(basic_ostreamstream<charT, traits, Allocator>& x,
                  basic_ostreamstream<charT, traits, Allocator>& y);

    using ostreamstream = basic_ostreamstream<char>;
    using wostreamstream = basic_ostreamstream<wchar_t>;

    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
        class basic_stringstream;

    template<class charT, class traits, class Allocator>
        void swap(basic_stringstream<charT, traits, Allocator>& x,
                  basic_stringstream<charT, traits, Allocator>& y);
```

```

using stringstream = basic_stringstream<char>;
using wstringstream = basic_stringstream<wchar_t>;
}

```

The header <sstream> defines four class templates and eight types that associate stream buffers with objects of class `basic_string`, as described in 23.4.

31.8.2 Class template `basic_stringbuf`

[stringbuf]

31.8.2.1 General

[stringbuf.general]

```

namespace std {
    template<class charT, class traits = char_traits<charT>,
            class Allocator = allocator<charT>>
    class basic_stringbuf : public basic_streambuf<charT, traits> {
    public:
        using char_type      = charT;
        using int_type       = typename traits::int_type;
        using pos_type       = typename traits::pos_type;
        using off_type       = typename traits::off_type;
        using traits_type    = traits;
        using allocator_type = Allocator;

        // 31.8.2.2, constructors
        basic_stringbuf() : basic_stringbuf(ios_base::in | ios_base::out) {}
        explicit basic_stringbuf(ios_base::openmode which);
        explicit basic_stringbuf(
            const basic_string<charT, traits, Allocator>& s,
            ios_base::openmode which = ios_base::in | ios_base::out);
        explicit basic_stringbuf(const Allocator& a)
            : basic_stringbuf(ios_base::in | ios_base::out, a) {}
        basic_stringbuf(ios_base::openmode which, const Allocator& a);
        explicit basic_stringbuf(
            basic_string<charT, traits, Allocator>&& s,
            ios_base::openmode which = ios_base::in | ios_base::out);
        template<class SAlloc>
        basic_stringbuf(
            const basic_string<charT, traits, SAlloc>& s, const Allocator& a)
            : basic_stringbuf(s, ios_base::in | ios_base::out, a) {}
        template<class SAlloc>
        basic_stringbuf(
            const basic_string<charT, traits, SAlloc>&& s,
            ios_base::openmode which, const Allocator& a);
        template<class SAlloc>
        explicit basic_stringbuf(
            const basic_string<charT, traits, SAlloc>& s,
            ios_base::openmode which = ios_base::in | ios_base::out);
        basic_stringbuf(const basic_stringbuf&) = delete;
        basic_stringbuf(basic_stringbuf&& rhs);
        basic_stringbuf(basic_stringbuf&& rhs, const Allocator& a);

        // 31.8.2.3, assignment and swap
        basic_stringbuf& operator=(const basic_stringbuf&) = delete;
        basic_stringbuf& operator=(basic_stringbuf&& rhs);
        void swap(basic_stringbuf& rhs) noexcept(see below);

        // 31.8.2.4, getters and setters
        allocator_type get_allocator() const noexcept;

        basic_string<charT, traits, Allocator> str() const &;
        template<class SAlloc>
        basic_string<charT, traits, SAlloc> str(const SAlloc& sa) const;
        basic_string<charT, traits, Allocator> str() &&;
        basic_string_view<charT, traits> view() const noexcept;
    };
}

```

```

void str(const basic_string<charT, traits, Allocator>& s);
template<class SAlloc>
    void str(const basic_string<charT, traits, SAlloc>& s);
void str(basic_string<charT, traits, Allocator>&& s);

protected:
    // 31.8.2.5, overridden virtual functions
    int_type underflow() override;
    int_type pbackfail(int_type c = traits::eof()) override;
    int_type overflow (int_type c = traits::eof()) override;
    basic_streambuf<charT, traits>* setbuf(charT*, streamsize) override;

    pos_type seekoff(off_type off, ios_base::seekdir way,
                    ios_base::openmode which
                    = ios_base::in | ios_base::out) override;
    pos_type seekpos(pos_type sp,
                    ios_base::openmode which
                    = ios_base::in | ios_base::out) override;

private:
    ios_base::openmode mode;                // exposition only
    basic_string<charT, traits, Allocator> buf; // exposition only
    void init_buf_ptrs();                   // exposition only
};

```

The class `basic_stringbuf` is derived from `basic_streambuf` to associate possibly the input sequence and possibly the output sequence with a sequence of arbitrary *characters*. The sequence can be initialized from, or made available as, an object of class `basic_string`.

For the sake of exposition, the maintained data and internal pointer initialization is presented here as:

- `ios_base::openmode` mode, has `in` set if the input sequence can be read, and `out` set if the output sequence can be written.
- `basic_string<charT, traits, Allocator>` `buf` contains the underlying character sequence.
- `init_buf_ptrs()` sets the base class' get area (31.6.3.4.2) and put area (31.6.3.4.3) pointers after initializing, moving from, or assigning to `buf` accordingly.

31.8.2.2 Constructors

[stringbuf.cons]

```
explicit basic_stringbuf(ios_base::openmode which);
```

Effects: Initializes the base class with `basic_streambuf()` (31.6.3.2), and mode with `which`. It is implementation-defined whether the sequence pointers (`eback()`, `gptr()`, `egptr()`, `pbase()`, `pptr()`, `epptr()`) are initialized to null pointers.

Postconditions: `str().empty()` is true.

```
explicit basic_stringbuf(
    const basic_string<charT, traits, Allocator>& s,
    ios_base::openmode which = ios_base::in | ios_base::out);
```

Effects: Initializes the base class with `basic_streambuf()` (31.6.3.2), mode with `which`, and `buf` with `s`, then calls `init_buf_ptrs()`.

```
basic_stringbuf(ios_base::openmode which, const Allocator &a);
```

Effects: Initializes the base class with `basic_streambuf()` (31.6.3.2), mode with `which`, and `buf` with `a`, then calls `init_buf_ptrs()`.

Postconditions: `str().empty()` is true.

```
explicit basic_stringbuf(
    basic_string<charT, traits, Allocator>&& s,
    ios_base::openmode which = ios_base::in | ios_base::out);
```

Effects: Initializes the base class with `basic_streambuf()` (31.6.3.2), mode with `which`, and `buf` with `std::move(s)`, then calls `init_buf_ptrs()`.

```
template<class SAlloc>
basic_stringbuf(
    const basic_string<charT, traits, SAlloc>& s,
    ios_base::openmode which, const Allocator& a);
```

Effects: Initializes the base class with `basic_streambuf()` (31.6.3.2), mode with `which`, and `buf` with `{s,a}`, then calls `init_buf_ptrs()`.

```
template<class SAlloc>
explicit basic_stringbuf(
    const basic_string<charT, traits, SAlloc>& s,
    ios_base::openmode which = ios_base::in | ios_base::out);
```

Constraints: `is_same_v<SAlloc, Allocator>` is false.

Effects: Initializes the base class with `basic_streambuf()` (31.6.3.2), mode with `which`, and `buf` with `s`, then calls `init_buf_ptrs()`.

```
basic_stringbuf(basic_stringbuf&& rhs);
basic_stringbuf(basic_stringbuf&& rhs, const Allocator& a);
```

Effects: Copy constructs the base class from `rhs` and initializes `mode` with `rhs.mode`. In the first form `buf` is initialized from `std::move(rhs).str()`. In the second form `buf` is initialized from `{std::move(rhs).str(), a}`. It is implementation-defined whether the sequence pointers in `*this` (`eback()`, `gptr()`, `egptr()`, `pbase()`, `pptr()`, `epptr()`) obtain the values which `rhs` had.

Postconditions: Let `rhs_p` refer to the state of `rhs` just prior to this construction and let `rhs_a` refer to the state of `rhs` just after this construction.

- `str() == rhs_p.str()`
- `gptr() - eback() == rhs_p.gptr() - rhs_p.eback()`
- `egptr() - eback() == rhs_p.egptr() - rhs_p.eback()`
- `pptr() - pbase() == rhs_p.pptr() - rhs_p.pbase()`
- `epptr() - pbase() == rhs_p.epptr() - rhs_p.pbase()`
- if (`eback()`) `eback() != rhs_a.eback()`
- if (`gptr()`) `gptr() != rhs_a.gptr()`
- if (`egptr()`) `egptr() != rhs_a.egptr()`
- if (`pbase()`) `pbase() != rhs_a.pbase()`
- if (`pptr()`) `pptr() != rhs_a.pptr()`
- if (`epptr()`) `epptr() != rhs_a.epptr()`
- `getloc() == rhs_p.getloc()`
- `rhs` is empty but usable, as if `std::move(rhs).str()` was called.

31.8.2.3 Assignment and swap

[stringbuf.assign]

```
basic_stringbuf& operator=(basic_stringbuf&& rhs);
```

Effects: After the move assignment `*this` has the observable state it would have had if it had been move constructed from `rhs` (see 31.8.2.2).

Returns: `*this`.

```
void swap(basic_stringbuf& rhs) noexcept(see below);
```

Preconditions: `allocator_traits<Allocator>::propagate_on_container_swap::value` is true or `get_allocator() == rhs.get_allocator()` is true.

Effects: Exchanges the state of `*this` and `rhs`.

Remarks: The exception specification is equivalent to:

```
allocator_traits<Allocator>::propagate_on_container_swap::value ||
allocator_traits<Allocator>::is_always_equal::value.
```

```
template<class charT, class traits, class Allocator>
void swap(basic_stringbuf<charT, traits, Allocator>& x,
         basic_stringbuf<charT, traits, Allocator>& y) noexcept(noexcept(x.swap(y)));
```

Effects: Equivalent to: `x.swap(y)`.

31.8.2.4 Member functions

[stringbuf.members]

The member functions getting the underlying character sequence all refer to a `high_mark` value, where `high_mark` represents the position one past the highest initialized character in the buffer. Characters can be initialized by writing to the stream, by constructing the `basic_stringbuf` passing a `basic_string` argument, or by calling one of the `str` member functions passing a `basic_string` as an argument. In the latter case, all characters initialized prior to the call are now considered uninitialized (except for those characters re-initialized by the new `basic_string`).

```
void init_buf_ptrs(); // exposition only
```

Effects: Initializes the input and output sequences from `buf` according to mode.

Postconditions:

- If `ios_base::out` is set in mode, `pbase()` points to `buf.front()` and `eptr() >= pbase() + buf.size()` is true;
 - in addition, if `ios_base::ate` is set in mode, `pptr() == pbase() + buf.size()` is true,
 - otherwise `pptr() == pbase()` is true.
- If `ios_base::in` is set in mode, `eback()` points to `buf.front()`, and `(gptr() == eback() && egptr() == eback() + buf.size())` is true.

NOTE 1 For efficiency reasons, stream buffer operations can violate invariants of `buf` while it is held encapsulated in the `basic_stringbuf`, e.g., by writing to characters in the range `[buf.data() + buf.size(), buf.data() + buf.capacity())`. All operations retrieving a `basic_string` from `buf` ensure that the `basic_string` invariants hold on the returned value.

```
allocator_type get_allocator() const noexcept;
```

Returns: `buf.get_allocator()`.

```
basic_string<charT, traits, Allocator> str() const &;
```

Effects: Equivalent to:

```
return basic_string<charT, traits, Allocator>(view(), get_allocator());
```

```
template<class SAlloc>
```

```
basic_string<charT, traits, SAlloc> str(const SAlloc& sa) const;
```

Constraints: `SAlloc` is a type that qualifies as an allocator (24.2.2.2).

Effects: Equivalent to:

```
return basic_string<charT, traits, SAlloc>(view(), sa);
```

```
basic_string<charT, traits, Allocator> str() &&;
```

Postconditions: The underlying character sequence `buf` is empty and `pbase()`, `pptr()`, `eptr()`, `eback()`, `gptr()`, and `egptr()` are initialized as if by calling `init_buf_ptrs()` with an empty `buf`.

Returns: A `basic_string<charT, traits, Allocator>` object move constructed from the `basic_stringbuf`'s underlying character sequence in `buf`. This can be achieved by first adjusting `buf` to have the same content as `view()`.

```
basic_string_view<charT, traits> view() const noexcept;
```

Let `sv` be `basic_string_view<charT, traits>`.

Returns: A `sv` object referring to the `basic_stringbuf`'s underlying character sequence in `buf`:

- If `ios_base::out` is set in mode, then `sv(pbase(), high_mark-pbase())` is returned.
- Otherwise, if `ios_base::in` is set in mode, then `sv(eback(), egptr()-eback())` is returned.
- Otherwise, `sv()` is returned.

NOTE 2 Using the returned `sv` object after destruction or invalidation of the character sequence underlying `*this` is undefined behavior, unless `sv.empty()` is `true`.

```
void str(const basic_string<charT, traits, Allocator>& s);
```

Effects: Equivalent to:

```
buf = s;
init_buf_ptrs();
```

```
template<class SAlloc>
```

```
void str(const basic_string<charT, traits, SAlloc>& s);
```

Constraints: `is_same_v<SAlloc, Allocator>` is `false`.

Effects: Equivalent to:

```
buf = s;
init_buf_ptrs();
```

```
void str(basic_string<charT, traits, Allocator>&& s);
```

Effects: Equivalent to:

```
buf = std::move(s);
init_buf_ptrs();
```

31.8.2.5 Overridden virtual functions

[stringbuf.virtuals]

```
int_type underflow() override;
```

Returns: If the input sequence has a read position available, returns `traits::to_int_type(*gptr())`. Otherwise, returns `traits::eof()`. Any character in the underlying buffer which has been initialized is considered to be part of the input sequence.

```
int_type pbackfail(int_type c = traits::eof()) override;
```

Effects: Puts back the character designated by `c` to the input sequence, if possible, in one of three ways:

- If `traits::eq_int_type(c, traits::eof())` returns `false` and if the input sequence has a putback position available, and if `traits::eq(to_char_type(c), gptr()[-1])` returns `true`, assigns `gptr() - 1` to `gptr()`.

Returns: `c`.

- If `traits::eq_int_type(c, traits::eof())` returns `false` and if the input sequence has a putback position available, and if `mode & ios_base::out` is nonzero, assigns `c` to `*--gptr()`.

Returns: `c`.

- If `traits::eq_int_type(c, traits::eof())` returns `true` and if the input sequence has a putback position available, assigns `gptr() - 1` to `gptr()`.

Returns: `traits::not_eof(c)`.

Returns: As specified above, or `traits::eof()` to indicate failure.

Remarks: If the function can succeed in more than one of these ways, it is unspecified which way is chosen.

```
int_type overflow(int_type c = traits::eof()) override;
```

Effects: Appends the character designated by `c` to the output sequence, if possible, in one of two ways:

- If `traits::eq_int_type(c, traits::eof())` returns `false` and if either the output sequence has a write position available or the function makes a write position available (as described below), the function calls `sputc(c)`.

Signals success by returning `c`.

- If `traits::eq_int_type(c, traits::eof())` returns `true`, there is no character to append.

Signals success by returning a value other than `traits::eof()`.

Returns: As specified above, or `traits::eof()` to indicate failure.

Remarks: The function can alter the number of write positions available as a result of any call.

The function can make a write position available only if `ios_base::out` is set in `mode`. To make a write position available, the function reallocates (or initially allocates) an array object with a sufficient number of elements to hold the current array object (if any), plus at least one additional write position. If `ios_base::in` is set in `mode`, the function alters the read end pointer `egptr()` to point just past the new write position.

```
pos_type seekoff(off_type off, ios_base::seekdir way,
                ios_base::openmode which
                = ios_base::in | ios_base::out) override;
```

Effects: Alters the stream position within one of the controlled sequences, if possible, as indicated in Table 126.

Table 126 — `seekoff` positioning [tab:stringbuf.seekoff.pos]

Conditions	Result
<code>ios_base::in</code> is set in <code>which</code>	positions the input sequence
<code>ios_base::out</code> is set in <code>which</code>	positions the output sequence
both <code>ios_base::in</code> and <code>ios_base::out</code> are set in <code>which</code> and either <code>way == ios_base::beg</code> or <code>way == ios_base::end</code>	positions both the input and the output sequences
Otherwise	the positioning operation fails.

For a sequence to be positioned, the function determines `newoff` as indicated in Table 127. If the sequence's next pointer (either `gptr()` or `pptr()`) is a null pointer and `newoff` is nonzero, the positioning operation fails.

Table 127 — `newoff` values [tab:stringbuf.seekoff.newoff]

Condition	<code>newoff</code> Value
<code>way == ios_base::beg</code>	0
<code>way == ios_base::cur</code>	the next pointer minus the beginning pointer (<code>xnext - xbeg</code>).
<code>way == ios_base::end</code>	the high mark pointer minus the beginning pointer (<code>high_mark - xbeg</code>).

If $(\text{newoff} + \text{off}) < 0$, or if `newoff + off` refers to an uninitialized character (31.8.2.4), the positioning operation fails. Otherwise, the function assigns `xbeg + newoff + off` to the next pointer `xnext`.

Returns: `pos_type(newoff)`, constructed from the resultant offset `newoff` (of type `off_type`), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is `pos_type(off_type(-1))`.

```
pos_type seekpos(pos_type sp,
                ios_base::openmode which
                = ios_base::in | ios_base::out) override;
```

Effects: Equivalent to `seekoff(off_type(sp), ios_base::beg, which)`.

Returns: `sp` to indicate success, or `pos_type(off_type(-1))` to indicate failure.

```
basic_streambuf<charT, traits>* setbuf(charT* s, streamsize n) override;
```

Effects: implementation-defined, except that `setbuf(0, 0)` has no effect.

Returns: `this`.

31.8.3 Class template `basic_istream`

[istream]

31.8.3.1 General

[istream.general]

```

namespace std {
    template<class charT, class traits = char_traits<charT>,
            class Allocator = allocator<charT>>
    class basic_istream : public basic_istream<charT, traits> {
    public:
        using char_type      = charT;
        using int_type       = typename traits::int_type;
        using pos_type       = typename traits::pos_type;
        using off_type       = typename traits::off_type;
        using traits_type    = traits;
        using allocator_type = Allocator;

        // 31.8.3.2, constructors
        basic_istream() : basic_istream(ios_base::in) {}
        explicit basic_istream(ios_base::openmode which);
        explicit basic_istream(
            const basic_string<charT, traits, Allocator>& s,
            ios_base::openmode which = ios_base::in);
        basic_istream(ios_base::openmode which, const Allocator& a);
        explicit basic_istream(
            basic_string<charT, traits, Allocator>&& s,
            ios_base::openmode which = ios_base::in);
        template<class SAlloc>
        basic_istream(
            const basic_string<charT, traits, SAlloc>& s, const Allocator& a)
            : basic_istream(s, ios_base::in, a) {}
        template<class SAlloc>
        basic_istream(
            const basic_string<charT, traits, SAlloc>&& s,
            ios_base::openmode which, const Allocator& a);
        template<class SAlloc>
        explicit basic_istream(
            const basic_string<charT, traits, SAlloc>& s,
            ios_base::openmode which = ios_base::in);
        basic_istream(const basic_istream&) = delete;
        basic_istream(basic_istream&& rhs);

        basic_istream& operator=(const basic_istream&) = delete;
        basic_istream& operator=(basic_istream&& rhs);

        // 31.8.3.3, swap
        void swap(basic_istream& rhs);

        // 31.8.3.4, members
        basic_stringbuf<charT, traits, Allocator>* rdbuf() const;
        basic_string<charT, traits, Allocator> str() const &;
        template<class SAlloc>
        basic_string<charT, traits, SAlloc> str(const SAlloc& sa) const;
        basic_string<charT, traits, Allocator> str() &&;
        basic_string_view<charT, traits> view() const noexcept;

        void str(const basic_string<charT, traits, Allocator>& s);
        template<class SAlloc>
        void str(const basic_string<charT, traits, SAlloc>& s);
        void str(basic_string<charT, traits, Allocator>&& s);

    private:
        basic_stringbuf<charT, traits, Allocator> sb;    // exposition only
    };
}

```

The class `basic_istream<charT, traits, Allocator>` supports reading objects of class `basic_string<charT, traits, Allocator>`. It uses a `basic_stringbuf<charT, traits, Allocator>` object to control the associated storage. For the sake of exposition, the maintained data is presented here as:

— `sb`, the `stringbuf` object.

31.8.3.2 Constructors

[istreamstream.cons]

```
explicit basic_istream(ios_base::openmode which);
```

Effects: Initializes the base class with `basic_istream<charT, traits>(addressof(sb))` (31.7.5.2) and `sb` with `basic_stringbuf<charT, traits, Allocator>(which | ios_base::in)` (31.8.2.2).

```
explicit basic_istream(
    const basic_string<charT, traits, Allocator>& s,
    ios_base::openmode which = ios_base::in);
```

Effects: Initializes the base class with `basic_istream<charT, traits>(addressof(sb))` (31.7.5.2) and `sb` with `basic_stringbuf<charT, traits, Allocator>(s, which | ios_base::in)` (31.8.2.2).

```
basic_istream(ios_base::openmode which, const Allocator& a);
```

Effects: Initializes the base class with `basic_istream<charT, traits>(addressof(sb))` (31.7.5.2) and `sb` with `basic_stringbuf<charT, traits, Allocator>(which | ios_base::in, a)` (31.8.2.2).

```
explicit basic_istream(
    basic_string<charT, traits, Allocator>&& s,
    ios_base::openmode which = ios_base::in);
```

Effects: Initializes the base class with `basic_istream<charT, traits>(addressof(sb))` (31.7.5.2) and `sb` with `basic_stringbuf<charT, traits, Allocator>(std::move(s), which | ios_base::in)` (31.8.2.2).

```
template<class SAlloc>
    basic_istream(
        const basic_string<charT, traits, SAlloc>& s,
        ios_base::openmode which, const Allocator& a);
```

Effects: Initializes the base class with `basic_istream<charT, traits>(addressof(sb))` (31.7.5.2) and `sb` with `basic_stringbuf<charT, traits, Allocator>(s, which | ios_base::in, a)` (31.8.2.2).

```
template<class SAlloc>
    explicit basic_istream(
        const basic_string<charT, traits, SAlloc>& s,
        ios_base::openmode which = ios_base::in);
```

Effects: Initializes the base class with `basic_istream<charT, traits>(addressof(sb))` (31.7.5.2) and `sb` with `basic_stringbuf<charT, traits, Allocator>(s, which | ios_base::in)` (31.8.2.2).

```
basic_istream(basic_istream&& rhs);
```

Effects: Move constructs from the rvalue `rhs`. This is accomplished by move constructing the base class, and the contained `basic_stringbuf`. Then calls `basic_istream<charT, traits>::set_rdbuf(addressof(sb))` to install the contained `basic_stringbuf`.

31.8.3.3 Swap

[istreamstream.swap]

```
void swap(basic_istream& rhs);
```

Effects: Equivalent to:

```
    basic_istream<charT, traits>::swap(rhs);
    sb.swap(rhs.sb);
```

```
template<class charT, class traits, class Allocator>
    void swap(basic_istream<charT, traits, Allocator>& x,
              basic_istream<charT, traits, Allocator>& y);
```

Effects: Equivalent to: `x.swap(y)`.

31.8.3.4 Member functions

[iostream.members]

```
basic_stringbuf<charT, traits, Allocator>* rdbuf() const;
```

Returns: `const_cast<basic_stringbuf<charT, traits, Allocator>*>(addressof(sb)).`

```
basic_string<charT, traits, Allocator> str() const &;
```

Effects: Equivalent to: `return rdbuf()->str();`

```
template<class SAlloc>
```

```
basic_string<charT, traits, SAlloc> str(const SAlloc& sa) const;
```

Effects: Equivalent to: `return rdbuf()->str(sa);`

```
basic_string<charT, traits, Allocator> str() &&;
```

Effects: Equivalent to: `return std::move(*rdbuf()).str();`

```
basic_string_view<charT, traits> view() const noexcept;
```

Effects: Equivalent to: `return rdbuf()->view();`

```
void str(const basic_string<charT, traits, Allocator>& s);
```

Effects: Equivalent to: `rdbuf()->str(s);`

```
template<class SAlloc>
```

```
void str(const basic_string<charT, traits, SAlloc>& s);
```

Effects: Equivalent to: `rdbuf()->str(s);`

```
void str(basic_string<charT, traits, Allocator>&& s);
```

Effects: Equivalent to: `rdbuf()->str(std::move(s));`

31.8.4 Class template basic_ostringstream

[ostreamstream]

31.8.4.1 General

[ostreamstream.general]

```
namespace std {
```

```
template<class charT, class traits = char_traits<charT>,
```

```
class Allocator = allocator<charT>>
```

```
class basic_ostringstream : public basic_ostream<charT, traits> {
```

```
public:
```

```
using char_type = charT;
```

```
using int_type = typename traits::int_type;
```

```
using pos_type = typename traits::pos_type;
```

```
using off_type = typename traits::off_type;
```

```
using traits_type = traits;
```

```
using allocator_type = Allocator;
```

```
// 31.8.4.2, constructors
```

```
basic_ostringstream() : basic_ostringstream(ios_base::out) {}
```

```
explicit basic_ostringstream(ios_base::openmode which);
```

```
explicit basic_ostringstream(
```

```
const basic_string<charT, traits, Allocator>& s,
```

```
ios_base::openmode which = ios_base::out);
```

```
basic_ostringstream(ios_base::openmode which, const Allocator& a);
```

```
explicit basic_ostringstream(
```

```
basic_string<charT, traits, Allocator>&& s,
```

```
ios_base::openmode which = ios_base::out);
```

```
template<class SAlloc>
```

```
basic_ostringstream(
```

```
const basic_string<charT, traits, SAlloc>& s, const Allocator& a)
```

```
: basic_ostringstream(s, ios_base::out, a) {}
```

```
template<class SAlloc>
```

```
basic_ostringstream(
```

```
const basic_string<charT, traits, SAlloc>& s,
```

```
ios_base::openmode which, const Allocator& a);
```

```

template<class SAlloc>
    explicit basic_ostringstream(
        const basic_string<charT, traits, SAlloc>& s,
        ios_base::openmode which = ios_base::out);
basic_ostringstream(const basic_ostringstream&) = delete;
basic_ostringstream(basic_ostringstream&& rhs);

basic_ostringstream& operator=(const basic_ostringstream&) = delete;
basic_ostringstream& operator=(basic_ostringstream&& rhs);

// 31.8.4.3, swap
void swap(basic_ostringstream& rhs);

// 31.8.4.4, members
basic_stringbuf<charT, traits, Allocator>* rdbuf() const;

basic_string<charT, traits, Allocator> str() const &;
template<class SAlloc>
    basic_string<charT, traits, SAlloc> str(const SAlloc& sa) const;
basic_string<charT, traits, Allocator> str() &&;
basic_string_view<charT, traits> view() const noexcept;

void str(const basic_string<charT, traits, Allocator>& s);
template<class SAlloc>
    void str(const basic_string<charT, traits, SAlloc>& s);
void str(basic_string<charT, traits, Allocator>&& s);

private:
    basic_stringbuf<charT, traits, Allocator> sb; // exposition only
};
}

```

The class `basic_ostringstream<charT, traits, Allocator>` supports writing objects of class `basic_string<charT, traits, Allocator>`. It uses a `basic_stringbuf` object to control the associated storage. For the sake of exposition, the maintained data is presented here as:

— sb, the `stringbuf` object.

31.8.4.2 Constructors

[`ostreamstream.cons`]

```
explicit basic_ostringstream(ios_base::openmode which);
```

Effects: Initializes the base class with `basic_ostream<charT, traits>(addressof(sb))` (31.7.6.2) and sb with `basic_stringbuf<charT, traits, Allocator>(which | ios_base::out)` (31.8.2.2).

```
explicit basic_ostringstream(
    const basic_string<charT, traits, Allocator>& s,
    ios_base::openmode which = ios_base::out);
```

Effects: Initializes the base class with `basic_ostream<charT, traits>(addressof(sb))` (31.7.6.2) and sb with `basic_stringbuf<charT, traits, Allocator>(s, which | ios_base::out)` (31.8.2.2).

```
basic_ostringstream(ios_base::openmode which, const Allocator& a);
```

Effects: Initializes the base class with `basic_ostream<charT, traits>(addressof(sb))` (31.7.6.2) and sb with `basic_stringbuf<charT, traits, Allocator>(which | ios_base::out, a)` (31.8.2.2).

```
explicit basic_ostringstream(
    basic_string<charT, traits, Allocator>&& s,
    ios_base::openmode which = ios_base::out);
```

Effects: Initializes the base class with `basic_ostream<charT, traits>(addressof(sb))` (31.7.6.2) and sb with `basic_stringbuf<charT, traits, Allocator>(std::move(s), which | ios_base::out)` (31.8.2.2).

```
template<class SAlloc>
basic_ostringstream(
    const basic_string<charT, traits, SAlloc>& s,
    ios_base::openmode which, const Allocator& a);
```

Effects: Initializes the base class with `basic_ostream<charT, traits>(addressof(sb))` (31.7.6.2) and `sb` with `basic_stringbuf<charT, traits, Allocator>(s, which | ios_base::out, a)` (31.8.2.2).

```
template<class SAlloc>
explicit basic_ostringstream(
    const basic_string<charT, traits, SAlloc>& s,
    ios_base::openmode which = ios_base::out);
```

Constraints: `is_same_v<SAlloc, Allocator>` is false.

Effects: Initializes the base class with `basic_ostream<charT, traits>(addressof(sb))` (31.7.6.2) and `sb` with `basic_stringbuf<charT, traits, Allocator>(s, which | ios_base::out)` (31.8.2.2).

```
basic_ostringstream(basic_ostringstream&& rhs);
```

Effects: Move constructs from the rvalue `rhs`. This is accomplished by move constructing the base class, and the contained `basic_stringbuf`. Then calls `basic_ostream<charT, traits>::set_rdbuf(addressof(sb))` to install the contained `basic_stringbuf`.

31.8.4.3 Swap

[ostreamstream.swap]

```
void swap(basic_ostringstream& rhs);
```

Effects: Equivalent to:

```
basic_ostream<charT, traits>::swap(rhs);
sb.swap(rhs.sb);
```

```
template<class charT, class traits, class Allocator>
void swap(basic_ostringstream<charT, traits, Allocator>& x,
         basic_ostringstream<charT, traits, Allocator>& y);
```

Effects: Equivalent to: `x.swap(y)`.

31.8.4.4 Member functions

[ostreamstream.members]

```
basic_stringbuf<charT, traits, Allocator>* rdbuf() const;
```

Returns: `const_cast<basic_stringbuf<charT, traits, Allocator>*>(addressof(sb))`.

```
basic_string<charT, traits, Allocator> str() const &;
```

Effects: Equivalent to: `return rdbuf()->str()`;

```
template<class SAlloc>
basic_string<charT, traits, SAlloc> str(const SAlloc& sa) const;
```

Effects: Equivalent to: `return rdbuf()->str(sa)`;

```
basic_string<charT, traits, Allocator> str() &&;
```

Effects: Equivalent to: `return std::move(*rdbuf()).str()`;

```
basic_string_view<charT, traits> view() const noexcept;
```

Effects: Equivalent to: `return rdbuf()->view()`;

```
void str(const basic_string<charT, traits, Allocator>& s);
```

Effects: Equivalent to: `rdbuf()->str(s)`;

```
template<class SAlloc>
void str(const basic_string<charT, traits, SAlloc>& s);
```

Effects: Equivalent to: `rdbuf()->str(s)`;

```
void str(basic_string<charT, traits, Allocator>&& s);
```

Effects: Equivalent to: `rdbuf()->str(std::move(s));`

31.8.5 Class template `basic_stringstream`

[stringstream]

31.8.5.1 General

[stringstream.general]

```
namespace std {
    template<class charT, class traits = char_traits<charT>,
            class Allocator = allocator<charT>>
    class basic_stringstream : public basic_istream<charT, traits> {
    public:
        using char_type      = charT;
        using int_type        = typename traits::int_type;
        using pos_type        = typename traits::pos_type;
        using off_type        = typename traits::off_type;
        using traits_type      = traits;
        using allocator_type   = Allocator;

        // 31.8.5.2, constructors
        basic_stringstream() : basic_stringstream(ios_base::out | ios_base::in) {}
        explicit basic_stringstream(ios_base::openmode which);
        explicit basic_stringstream(
            const basic_string<charT, traits, Allocator>& s,
            ios_base::openmode which = ios_base::out | ios_base::in);
        basic_stringstream(ios_base::openmode which, const Allocator& a);
        explicit basic_stringstream(
            basic_string<charT, traits, Allocator>&& s,
            ios_base::openmode which = ios_base::out | ios_base::in);
        template<class SAlloc>
        basic_stringstream(
            const basic_string<charT, traits, SAlloc>& s, const Allocator& a)
            : basic_stringstream(s, ios_base::out | ios_base::in, a) {}
        template<class SAlloc>
        basic_stringstream(
            const basic_string<charT, traits, SAlloc>& s,
            ios_base::openmode which, const Allocator& a);
        template<class SAlloc>
        explicit basic_stringstream(
            const basic_string<charT, traits, SAlloc>& s,
            ios_base::openmode which = ios_base::out | ios_base::in);
        basic_stringstream(const basic_stringstream&) = delete;
        basic_stringstream(basic_stringstream&& rhs);

        basic_stringstream& operator=(const basic_stringstream&) = delete;
        basic_stringstream& operator=(basic_stringstream&& rhs);

        // 31.8.5.3, swap
        void swap(basic_stringstream& rhs);

        // 31.8.5.4, members
        basic_stringbuf<charT, traits, Allocator>* rdbuf() const;

        basic_string<charT, traits, Allocator> str() const &;
        template<class SAlloc>
        basic_string<charT, traits, SAlloc> str(const SAlloc& sa) const;
        basic_string<charT, traits, Allocator> str() &&;
        basic_string_view<charT, traits> view() const noexcept;

        void str(const basic_string<charT, traits, Allocator>& s);
        template<class SAlloc>
        void str(const basic_string<charT, traits, SAlloc>& s);
        void str(basic_string<charT, traits, Allocator>&& s);
```

```
private:
    basic_stringbuf<charT, traits, Allocator> sb;    // exposition only
};
}
```

The class template `basic_stringstream<charT, traits>` supports reading and writing from objects of class `basic_string<charT, traits, Allocator>`. It uses a `basic_stringbuf<charT, traits, Allocator>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as

— `sb`, the `stringbuf` object.

31.8.5.2 Constructors

[`stringstream.cons`]

```
explicit basic_stringstream(ios_base::openmode which);
```

Effects: Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` (31.7.5.7.2) and `sb` with `basic_stringbuf<charT, traits, Allocator>(which)`.

```
explicit basic_stringstream(
    const basic_string<charT, traits, Allocator>& s,
    ios_base::openmode which = ios_base::out | ios_base::in);
```

Effects: Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` (31.7.5.7.2) and `sb` with `basic_stringbuf<charT, traits, Allocator>(s, which)`.

```
basic_stringstream(ios_base::openmode which, const Allocator& a);
```

Effects: Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` (31.7.5.7.2) and `sb` with `basic_stringbuf<charT, traits, Allocator>(which, a)` (31.8.2.2).

```
explicit basic_stringstream(
    basic_string<charT, traits, Allocator>&& s,
    ios_base::openmode which = ios_base::out | ios_base::in);
```

Effects: Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` (31.7.5.7.2) and `sb` with `basic_stringbuf<charT, traits, Allocator>(std::move(s), which)` (31.8.2.2).

```
template<class SAlloc>
basic_stringstream(
    const basic_string<charT, traits, SAlloc>& s,
    ios_base::openmode which, const Allocator& a);
```

Effects: Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` (31.7.5.7.2) and `sb` with `basic_stringbuf<charT, traits, Allocator>(s, which, a)` (31.8.2.2).

```
template<class SAlloc>
explicit basic_stringstream(
    const basic_string<charT, traits, SAlloc>& s,
    ios_base::openmode which = ios_base::out | ios_base::in);
```

Constraints: `is_same_v<SAlloc, Allocator>` is false.

Effects: Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` (31.7.5.7.2) and `sb` with `basic_stringbuf<charT, traits, Allocator>(s, which)` (31.8.2.2).

```
basic_stringstream(basic_stringstream&& rhs);
```

Effects: Move constructs from the rvalue `rhs`. This is accomplished by move constructing the base class, and the contained `basic_stringbuf`. Then calls `basic_istream<charT, traits>::set_rdbuf(addressof(sb))` to install the contained `basic_stringbuf`.

31.8.5.3 Swap

[`stringstream.swap`]

```
void swap(basic_stringstream& rhs);
```

Effects: Equivalent to:

```
basic_istream<charT, traits>::swap(rhs);
sb.swap(rhs.sb);
```

```
template<class charT, class traits, class Allocator>
void swap(basic_stringstream<charT, traits, Allocator>& x,
         basic_stringstream<charT, traits, Allocator>& y);
```

Effects: Equivalent to: `x.swap(y)`.

31.8.5.4 Member functions

[[stringstream.members](#)]

```
basic_stringbuf<charT, traits, Allocator>* rdbuf() const;
```

Returns: `const_cast<basic_stringbuf<charT, traits, Allocator>*>(addressof(sb))`.

```
basic_string<charT, traits, Allocator> str() const &;
```

Effects: Equivalent to: `return rdbuf()->str()`;

```
template<class SAlloc>
```

```
basic_string<charT, traits, SAlloc> str(const SAlloc& sa) const;
```

Effects: Equivalent to: `return rdbuf()->str(sa)`;

```
basic_string<charT, traits, Allocator> str() &&;
```

Effects: Equivalent to: `return std::move(*rdbuf()).str()`;

```
basic_string_view<charT, traits> view() const noexcept;
```

Effects: Equivalent to: `return rdbuf()->view()`;

```
void str(const basic_string<charT, traits, Allocator>& s);
```

Effects: Equivalent to: `rdbuf()->str(s)`;

```
template<class SAlloc>
```

```
void str(const basic_string<charT, traits, SAlloc>& s);
```

Effects: Equivalent to: `rdbuf()->str(s)`;

```
void str(basic_string<charT, traits, Allocator>&& s);
```

Effects: Equivalent to: `rdbuf()->str(std::move(s))`;

31.9 Span-based streams

[[span.streams](#)]

31.9.1 Overview

[[span.streams.overview](#)]

The header `<spanstream>` defines class templates and types that associate stream buffers with objects whose types are specializations of `span` as described in [24.7.2.2](#).

NOTE A user of these classes is responsible for ensuring that the character sequence represented by the given `span` outlives the use of the sequence by objects of the classes in [31.9](#). Using multiple `basic_spanbuf` objects referring to overlapping underlying sequences from different threads, where at least one `basic_spanbuf` object is used for writing to the sequence, results in a data race.

31.9.2 Header `<spanstream>` synopsis

[[spanstream.syn](#)]

```
namespace std {
    template<class charT, class traits = char_traits<charT>>
        class basic_spanbuf;

    template<class charT, class traits>
        void swap(basic_spanbuf<charT, traits>& x, basic_spanbuf<charT, traits>& y);

    using spanbuf = basic_spanbuf<char>;
    using wspanbuf = basic_spanbuf<wchar_t>;

    template<class charT, class traits = char_traits<charT>>
        class basic_ispanstream;

    template<class charT, class traits>
        void swap(basic_ispanstream<charT, traits>& x, basic_ispanstream<charT, traits>& y);
```

```

using ispanstream = basic_ispanstream<char>;
using wspanstream = basic_ispanstream<wchar_t>;

template<class charT, class traits = char_traits<charT>>
    class basic_ostream;

template<class charT, class traits>
    void swap(basic_ostream<charT, traits>& x, basic_ostream<charT, traits>& y);

using ostream = basic_ostream<char>;
using wostream = basic_ostream<wchar_t>;

template<class charT, class traits = char_traits<charT>>
    class basic_spanstream;

template<class charT, class traits>
    void swap(basic_spanstream<charT, traits>& x, basic_spanstream<charT, traits>& y);

using spanstream = basic_spanstream<char>;
using wspanstream = basic_spanstream<wchar_t>;
}

```

31.9.3 Class template basic_spanbuf

[spanbuf]

31.9.3.1 General

[spanbuf.general]

```

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_spanbuf
    : public basic_streambuf<charT, traits> {
    public:
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;

        // 31.9.3.2, constructors
        basic_spanbuf() : basic_spanbuf(ios_base::in | ios_base::out) {}
        explicit basic_spanbuf(ios_base::openmode which)
            : basic_spanbuf(std::span<charT>(), which) {}
        explicit basic_spanbuf(std::span<charT> s,
            ios_base::openmode which = ios_base::in | ios_base::out);
        basic_spanbuf(const basic_spanbuf&) = delete;
        basic_spanbuf(basic_spanbuf&& rhs);

        // 31.9.3.3, assignment and swap
        basic_spanbuf& operator=(const basic_spanbuf&) = delete;
        basic_spanbuf& operator=(basic_spanbuf&& rhs);
        void swap(basic_spanbuf& rhs);

        // 31.9.3.4, member functions
        std::span<charT> span() const noexcept;
        void span(std::span<charT> s) noexcept;

    protected:
        // 31.9.3.5, overridden virtual functions
        basic_streambuf<charT, traits>* setbuf(charT*, streamsize) override;
        pos_type seekoff(off_type off, ios_base::seekdir way,
            ios_base::openmode which = ios_base::in | ios_base::out) override;
        pos_type seekpos(pos_type sp,
            ios_base::openmode which = ios_base::in | ios_base::out) override;

    private:
        ios_base::openmode mode; // exposition only
    };
}

```

```

    std::span<charT> buf;                // exposition only
};
}

```

The class template `basic_spanbuf` is derived from `basic_streambuf` to associate possibly the input sequence and possibly the output sequence with a sequence of arbitrary characters. The sequence is provided by an object of class `span<charT>`.

For the sake of exposition, the maintained data is presented here as:

- `ios_base::openmode mode`, has in set if the input sequence can be read, and out set if the output sequence can be written.
- `std::span<charT> buf` is the view to the underlying character sequence.

31.9.3.2 Constructors [spanbuf.cons]

```

explicit basic_spanbuf(std::span<charT> s,
                      ios_base::openmode which = ios_base::in | ios_base::out);

```

Effects: Initializes the base class with `basic_streambuf()` (31.6.3.2), and `mode` with `which`. Initializes the internal pointers as if calling `span(s)`.

```

basic_spanbuf(basic_spanbuf&& rhs);

```

Effects: Initializes the base class with `std::move(rhs)` and `mode` with `std::move(rhs.mode)` and `buf` with `std::move(rhs.buf)`. The sequence pointers in `*this` (`eback()`, `gptr()`, `egptr()`, `pbase()`, `pptr()`, `epptr()`) obtain the values which `rhs` had. It is implementation-defined whether `rhs.buf.empty()` returns `true` after the move.

Postconditions: Let `rhs_p` refer to the state of `rhs` just prior to this construction.

- `span().data() == rhs_p.span().data()`
- `span().size() == rhs_p.span().size()`
- `eback() == rhs_p.eback()`
- `gptr() == rhs_p.gptr()`
- `egptr() == rhs_p.egptr()`
- `pbase() == rhs_p.pbase()`
- `pptr() == rhs_p.pptr()`
- `epptr() == rhs_p.epptr()`
- `getloc() == rhs_p.getloc()`

31.9.3.3 Assignment and swap [spanbuf.assign]

```

basic_spanbuf& operator=(basic_spanbuf&& rhs);

```

Effects: Equivalent to:

```

    basic_spanbuf tmp{std::move(rhs)};
    this->swap(tmp);
    return *this;

```

```

void swap(basic_spanbuf& rhs);

```

Effects: Equivalent to:

```

    basic_streambuf<charT, traits>::swap(rhs);
    std::swap(mode, rhs.mode);
    std::swap(buf, rhs.buf);

```

```

template<class charT, class traits>

```

```

    void swap(basic_spanbuf<charT, traits>& x, basic_spanbuf<charT, traits>& y);

```

Effects: Equivalent to `x.swap(y)`.

31.9.3.4 Member functions [spanbuf.members]

```
std::span<charT> span() const noexcept;
```

Returns: If `ios_base::out` is set in *mode*, returns `std::span<charT>(pbase(), pptr())`, otherwise returns *buf*.

NOTE In contrast to `basic_stringbuf`, the underlying sequence never grows and is not owned. An owning copy can be obtained by converting the result to `basic_string<charT>`.

```
void span(std::span<charT> s) noexcept;
```

Effects: *buf* = *s*. Initializes the input and output sequences according to *mode*.

Postconditions:

- If `ios_base::out` is set in *mode*, `pbase() == s.data() && epptr() == pbase() + s.size()` is true;
 - in addition, if `ios_base::ate` is set in *mode*, `pptr() == pbase() + s.size()` is true,
 - otherwise `pptr() == pbase()` is true.
- If `ios_base::in` is set in *mode*, `eback() == s.data() && gptra() == eback() && egptra() == eback() + s.size()` is true.

31.9.3.5 Overridden virtual functions

[`spanbuf.virtuals`]

NOTE Because the underlying buffer is of fixed size, neither `overflow`, `underflow`, nor `pbackfail` can provide useful behavior.

```
pos_type seekoff(off_type off, ios_base::seekdir way,
                ios_base::openmode which = ios_base::in | ios_base::out) override;
```

Effects: Alters the stream position within one or both of the controlled sequences, if possible, as follows:

- If `ios_base::in` is set in *which*, positions the input sequence; *xnext* is `gptra()`, *xbeg* is `eback()`.
- If `ios_base::out` is set in *which*, positions the output sequence; *xnext* is `pptra()`, *xbeg* is `pbase()`.

If both `ios_base::in` and `ios_base::out` are set in *which* and *way* is `ios_base::cur`, the positioning operation fails.

For a sequence to be positioned, if its next pointer *xnext* (either `gptra()` or `pptra()`) is a null pointer and the new offset *newoff* as computed below is nonzero, the positioning operation fails. Otherwise, the function determines *baseoff* as a value of type *off_type* as follows:

- 0 when *way* is `ios_base::beg`;
- `(pptra() - pbase())` for the output sequence, or `(gptra() - eback())` for the input sequence when *way* is `ios_base::cur`;
- when *way* is `ios_base::end`:
 - `(pptra() - pbase())` if `ios_base::out` is set in *mode* and `ios_base::in` is not set in *mode*,
 - `buf.size()` otherwise.

If *baseoff* + *off* would overflow, or if *baseoff* + *off* is less than zero, or if *baseoff* + *off* is greater than `buf.size()`, the positioning operation fails. Otherwise, the function computes

```
off_type newoff = baseoff + off;
```

and assigns `xbeg + newoff` to the next pointer *xnext*.

Returns: `pos_type(off_type(-1))` if the positioning operation fails; `pos_type(newoff)` otherwise.

```
pos_type seekpos(pos_type sp, ios_base::openmode which = ios_base::in | ios_base::out) override;
```

Effects: Equivalent to:

```
return seekoff(off_type(sp), ios_base::beg, which);
```

```
basic_streambuf<charT, traits>* setbuf(charT* s, streamsize n) override;
```

Effects: Equivalent to:

```
this->span(std::span<charT>(s, n));
return this;
```

31.9.4 Class template basic_ispanstream**[ispanstream]****31.9.4.1 General****[ispanstream.general]**

```

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_ispanstream
        : public basic_istream<charT, traits> {
    public:
        using char_type      = charT;
        using int_type        = typename traits::int_type;
        using pos_type        = typename traits::pos_type;
        using off_type        = typename traits::off_type;
        using traits_type     = traits;

        // 31.9.4.2, constructors
        explicit basic_ispanstream(std::span<charT> s,
                                   ios_base::openmode which = ios_base::in);
        basic_ispanstream(const basic_ispanstream&) = delete;
        basic_ispanstream(basic_ispanstream&& rhs);
        template<class ROS> explicit basic_ispanstream(ROS&& s);

        basic_ispanstream& operator=(const basic_ispanstream&) = delete;
        basic_ispanstream& operator=(basic_ispanstream&& rhs);

        // 31.9.4.3, swap
        void swap(basic_ispanstream& rhs);

        // 31.9.4.4, member functions
        basic_spanbuf<charT, traits>* rdbuf() const noexcept;

        std::span<const charT> span() const noexcept;
        void span(std::span<charT> s) noexcept;
        template<class ROS> void span(ROS&& s) noexcept;

    private:
        basic_spanbuf<charT, traits> sb; // exposition only
    };
}

```

NOTE Constructing an `ispanstream` from a *string-literal* includes the termination character `'\0'` in the underlying `spanbuf`.

31.9.4.2 Constructors**[ispanstream.cons]**

```
explicit basic_ispanstream(std::span<charT> s, ios_base::openmode which = ios_base::in);
```

Effects: Initializes the base class with `basic_istream<charT, traits>(addressof(sb))` and `sb` with `basic_spanbuf<charT, traits>(s, which | ios_base::in)` (31.9.3.2).

```
basic_ispanstream(basic_ispanstream&& rhs);
```

Effects: Initializes the base class with `std::move(rhs)` and `sb` with `std::move(rhs.sb)`. Next, `basic_istream<charT, traits>::set_rdbuf(addressof(sb))` is called to install the contained `basic_spanbuf`.

```
template<class ROS> explicit basic_ispanstream(ROS&& s)
```

Constraints: `ROS` models `ranges::borrowed_range`. `!convertible_to<ROS, std::span<charT>>> && convertible_to<ROS, std::span<charT const>>` is true.

Effects: Let `sp` be `std::span<const charT>(std::forward<ROS>(s))`. Equivalent to `basic_ispanstream(std::span<charT>(const_cast<charT*>(sp.data()), sp.size()))`

31.9.4.3 Swap**[ispanstream.swap]**

```
void swap(basic_ispanstream& rhs);
```

Effects: Equivalent to:

```
basic_istream<charT, traits>::swap(rhs);
sb.swap(rhs.sb);
```

```
template<class charT, class traits>
```

```
void swap(basic_ispanstream<charT, traits>& x, basic_ispanstream<charT, traits>& y);
```

Effects: Equivalent to `x.swap(y)`.

31.9.4.4 Member functions

[ispanstream.members]

```
basic_spanbuf<charT, traits>* rdbuf() const noexcept;
```

Effects: Equivalent to:

```
return const_cast<basic_spanbuf<charT, traits>*>(addressof(sb));
```

```
std::span<const charT> span() const noexcept;
```

Effects: Equivalent to: `return rdbuf()->span();`

```
void span(std::span<charT> s) noexcept;
```

Effects: Equivalent to `rdbuf()->span(s)`.

```
template<class ROS> void span(ROS&& s) noexcept;
```

Constraints: `ROS` models `ranges::borrowed_range`. (!`convertible_to<ROS, std::span<charT>>`)
&& `convertible_to<ROS, std::span<const charT>>` is true.

Effects: Let `sp` be `std::span<const charT>(std::forward<ROS>(s))`. Equivalent to:

```
this->span(std::span<charT>(const_cast<charT*>(sp.data()), sp.size()))
```

31.9.5 Class template `basic_ostream`

[ostream]

31.9.5.1 General

[ostream.general]

```
namespace std {
```

```
template<class charT, class traits = char_traits<charT>>
```

```
class basic_ostream
```

```
: public basic_ostream<charT, traits> {
```

```
public:
```

```
using char_type = charT;
```

```
using int_type = typename traits::int_type;
```

```
using pos_type = typename traits::pos_type;
```

```
using off_type = typename traits::off_type;
```

```
using traits_type = traits;
```

```
// 31.9.5.2, constructors
```

```
explicit basic_ostream(std::span<charT> s,
```

```
ios_base::openmode which = ios_base::out);
```

```
basic_ostream(const basic_ostream&) = delete;
```

```
basic_ostream(basic_ostream&& rhs);
```

```
basic_ostream& operator=(const basic_ostream&) = delete;
```

```
basic_ostream& operator=(basic_ostream&& rhs);
```

```
// 31.9.5.3, swap
```

```
void swap(basic_ostream& rhs);
```

```
// 31.9.5.4, member functions
```

```
basic_spanbuf<charT, traits>* rdbuf() const noexcept;
```

```
std::span<charT> span() const noexcept;
```

```
void span(std::span<charT> s) noexcept;
```

```
private:
    basic_spanbuf<charT, traits> sb;    // exposition only
};
}
```

31.9.5.2 Constructors

[ospanstream.cons]

```
explicit basic_ospanstream(std::span<charT> s,
                           ios_base::openmode which = ios_base::out);
```

Effects: Initializes the base class with `basic_ostream<charT, traits>(addressof(sb))` and `sb` with `basic_spanbuf<charT, traits>(s, which | ios_base::out)` (31.9.3.2).

```
basic_ospanstream(basic_ospanstream&& rhs) noexcept;
```

Effects: Initializes the base class with `std::move(rhs)` and `sb` with `std::move(rhs.sb)`. Next, `basic_ostream<charT, traits>::set_rdbuf(addressof(sb))` is called to install the contained `basic_spanbuf`.

31.9.5.3 Swap

[ospanstream.swap]

```
void swap(basic_ospanstream& rhs);
```

Effects: Equivalent to:

```
    basic_ostream<charT, traits>::swap(rhs);
    sb.swap(rhs.sb);
```

```
template<class charT, class traits>
```

```
void swap(basic_ospanstream<charT, traits>& x, basic_ospanstream<charT, traits>& y);
```

Effects: Equivalent to `x.swap(y)`.

31.9.5.4 Member functions

[ospanstream.members]

```
basic_spanbuf<charT, traits>* rdbuf() const noexcept;
```

Effects: Equivalent to:

```
    return const_cast<basic_spanbuf<charT, traits>*>(addressof(sb));
```

```
std::span<charT> span() const noexcept;
```

Effects: Equivalent to: `return rdbuf()->span();`

```
void span(std::span<charT> s) noexcept;
```

Effects: Equivalent to `rdbuf()->span(s)`.

31.9.6 Class template `basic_spanstream`

[spanstream]

31.9.6.1 General

[spanstream.general]

```
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_spanstream
    : public basic_istream<charT, traits> {
    public:
        using char_type    = charT;
        using int_type      = typename traits::int_type;
        using pos_type      = typename traits::pos_type;
        using off_type      = typename traits::off_type;
        using traits_type    = traits;

        // 31.9.6.2, constructors
        explicit basic_spanstream(std::span<charT> s,
                                ios_base::openmode which = ios_base::out | ios_base::in);

        basic_spanstream(const basic_spanstream&) = delete;
        basic_spanstream(basic_spanstream&& rhs);

        basic_spanstream& operator=(const basic_spanstream&) = delete;
        basic_spanstream& operator=(basic_spanstream&& rhs);
    };
}
```

```

// 31.9.6.3, swap
void swap(basic_spanstream& rhs);

// 31.9.6.4, members
basic_spanbuf<charT, traits>* rdbuf() const noexcept;

std::span<charT> span() const noexcept;
void span(std::span<charT> s) noexcept;

private:
    basic_spanbuf<charT, traits> sb;    // exposition only
};
}

```

31.9.6.2 Constructors [spanstream.cons]

```
explicit basic_spanstream(std::span<charT> s,
                          ios_base::openmode which = ios_base::out | ios_base::in);
```

Effects: Initializes the base class with `basic_istream<charT, traits>(addressof(sb))` and `sb` with `basic_spanbuf<charT, traits>(s, which)` (31.9.3.2).

```
basic_spanstream(basic_spanstream&& rhs);
```

Effects: Initializes the base class with `std::move(rhs)` and `sb` with `std::move(rhs.sb)`. Next, `basic_istream<charT, traits>::set_rdbuf(addressof(sb))` is called to install the contained `basic_spanbuf`.

31.9.6.3 Swap [spanstream.swap]

```
void swap(basic_spanstream& rhs);
```

Effects: Equivalent to:

```
    basic_istream<charT, traits>::swap(rhs);
    sb.swap(rhs.sb);
```

```
template<class charT, class traits>
void swap(basic_spanstream<charT, traits>& x, basic_spanstream<charT, traits>& y);
```

Effects: Equivalent to `x.swap(y)`.

31.9.6.4 Member functions [spanstream.members]

```
basic_spanbuf<charT, traits>* rdbuf() const noexcept;
```

Effects: Equivalent to:

```
    return const_cast<basic_spanbuf<charT, traits>*>(addressof(sb));
```

```
std::span<charT> span() const noexcept;
```

Effects: Equivalent to: `return rdbuf()->span();`

```
void span(std::span<charT> s) noexcept;
```

Effects: Equivalent to `rdbuf()->span(s)`.

31.10 File-based streams [file.streams]

31.10.1 Header <fstream> synopsis [fstream.syn]

```

namespace std {
    template<class charT, class traits = char_traits<charT>>
        class basic_filebuf;

    template<class charT, class traits>
        void swap(basic_filebuf<charT, traits>& x, basic_filebuf<charT, traits>& y);

    using filebuf = basic_filebuf<char>;
    using wfilebuf = basic_filebuf<wchar_t>;
}

```

```

template<class charT, class traits = char_traits<charT>>
    class basic_ifstream;

template<class charT, class traits>
    void swap(basic_ifstream<charT, traits>& x, basic_ifstream<charT, traits>& y);

using ifstream = basic_ifstream<char>;
using wifstream = basic_ifstream<wchar_t>;

template<class charT, class traits = char_traits<charT>>
    class basic_ofstream;

template<class charT, class traits>
    void swap(basic_ofstream<charT, traits>& x, basic_ofstream<charT, traits>& y);

using ofstream = basic_ofstream<char>;
using wofstream = basic_ofstream<wchar_t>;

template<class charT, class traits = char_traits<charT>>
    class basic_fstream;

template<class charT, class traits>
    void swap(basic_fstream<charT, traits>& x, basic_fstream<charT, traits>& y);

using fstream = basic_fstream<char>;
using wfstream = basic_fstream<wchar_t>;
}

```

The header `<fstream>` defines four class templates and eight types that associate stream buffers with files and assist reading and writing files.

NOTE 1 The class template `basic_filebuf` treats a file as a source or sink of bytes. In an environment that uses a large character set, the file typically holds multibyte character sequences and the `basic_filebuf` object converts those multibyte sequences into wide character sequences.

In subclause 31.10, member functions taking arguments of `const filesystem::path::value_type*` are only provided on systems where `filesystem::path::value_type` (31.12.6) is not `char`.

NOTE 2 These functions enable class `path` support for systems with a wide native path character type, such as `wchar_t`.

31.10.2 Class template `basic_filebuf`

[filebuf]

31.10.2.1 General

[filebuf.general]

```

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_filebuf : public basic_streambuf<charT, traits> {
    public:
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;

        // 31.10.2.2, constructors/destructor
        basic_filebuf();
        basic_filebuf(const basic_filebuf&) = delete;
        basic_filebuf(basic_filebuf&& rhs);
        virtual ~basic_filebuf();

        // 31.10.2.3, assignment and swap
        basic_filebuf& operator=(const basic_filebuf&) = delete;
        basic_filebuf& operator=(basic_filebuf&& rhs);
        void swap(basic_filebuf& rhs);
    };
}

```

```

// 31.10.2.4, members
bool is_open() const;
basic_filebuf* open(const char* s, ios_base::openmode mode);
basic_filebuf* open(const filesystem::path::value_type* s,
                    ios_base::openmode mode); // wide systems only; see 31.10.1
basic_filebuf* open(const string& s,
                    ios_base::openmode mode);
basic_filebuf* open(const filesystem::path& s,
                    ios_base::openmode mode);
basic_filebuf* close();

protected:
// 31.10.2.5, overridden virtual functions
streamsize showmanyc() override;
int_type underflow() override;
int_type uflow() override;
int_type pbackfail(int_type c = traits::eof()) override;
int_type overflow (int_type c = traits::eof()) override;

basic_streambuf<charT, traits>* setbuf(char_type* s,
                                     streamsize n) override;
pos_type seekoff(off_type off, ios_base::seekdir way,
                 ios_base::openmode which
                 = ios_base::in | ios_base::out) override;
pos_type seekpos(pos_type sp,
                 ios_base::openmode which
                 = ios_base::in | ios_base::out) override;
int      sync() override;
void     imbue(const locale& loc) override;
};
}

```

The class `basic_filebuf<charT, traits>` associates both the input sequence and the output sequence with a file.

The restrictions on reading and writing a sequence controlled by an object of class `basic_filebuf<charT, traits>` are the same as for reading and writing with the C standard library `FILES`.

In particular:

- If the file is not open for reading, the input sequence cannot be read.
- If the file is not open for writing the output sequence cannot be written.
- A joint file position is maintained for both the input sequence and the output sequence.

An instance of `basic_filebuf` behaves as described in 31.10.2 provided `traits::pos_type` is `fpos<traits::state_type>`. Otherwise the behavior is undefined.

In order to support file I/O and multibyte/wide character conversion, conversions are performed using members of a facet, referred to as `a_codecvt` in following subclauses, obtained as if by

```

const codecvt<charT, char, typename traits::state_type>& a_codecvt =
    use_facet<codecvt<charT, char, typename traits::state_type>>(getloc());

```

31.10.2.2 Constructors

[filebuf.cons]

```
basic_filebuf();
```

Effects: Initializes the base class with `basic_streambuf<charT, traits>()` (31.6.3.2).

Postconditions: `is_open() == false`.

```
basic_filebuf(basic_filebuf&& rhs);
```

Effects: It is implementation-defined whether the sequence pointers in `*this` (`eback()`, `gptr()`, `egptr()`, `pbase()`, `pptr()`, `epptr()`) obtain the values which `rhs` had. Whether they do or not, `*this` and `rhs` reference separate buffers (if any at all) after the construction. Additionally `*this` references the file which `rhs` did before the construction, and `rhs` references no file after the construction. The openmode, locale and any other state of `rhs` is also copied.

Postconditions: Let `rhs_p` refer to the state of `rhs` just prior to this construction and let `rhs_a` refer to the state of `rhs` just after this construction.

```

— is_open() == rhs_p.is_open()
— rhs_a.is_open() == false
— gptr() - eback() == rhs_p.gptr() - rhs_p.eback()
— egptr() - eback() == rhs_p.egptr() - rhs_p.eback()
— pptr() - pbase() == rhs_p.pptr() - rhs_p.pbase()
— epptr() - pbase() == rhs_p.epptr() - rhs_p.pbase()
— if (eback()) eback() != rhs_a.eback()
— if (gptr()) gptr() != rhs_a.gptr()
— if (egptr()) egptr() != rhs_a.egptr()
— if (pbase()) pbase() != rhs_a.pbase()
— if (pptr()) pptr() != rhs_a.pptr()
— if (epptr()) epptr() != rhs_a.epptr()

```

```
virtual ~basic_filebuf();
```

Effects: Calls `close()`. If an exception occurs during the destruction of the object, including the call to `close()`, the exception is caught but not rethrown (see 16.4.6.13).

31.10.2.3 Assignment and swap

[filebuf.assign]

```
basic_filebuf& operator=(basic_filebuf&& rhs);
```

Effects: Calls `close()` then move assigns from `rhs`. After the move assignment `*this` has the observable state it would have had if it had been move constructed from `rhs` (see 31.10.2.2).

Returns: `*this`.

```
void swap(basic_filebuf& rhs);
```

Effects: Exchanges the state of `*this` and `rhs`.

```

template<class charT, class traits>
void swap(basic_filebuf<charT, traits>& x, basic_filebuf<charT, traits>& y);

```

Effects: Equivalent to: `x.swap(y)`.

31.10.2.4 Member functions

[filebuf.members]

```
bool is_open() const;
```

Returns: `true` if a previous call to `open` succeeded (returned a non-null value) and there has been no intervening call to `close`.

```

basic_filebuf* open(const char* s, ios_base::openmode mode);
basic_filebuf* open(const filesystem::path::value_type* s,
    ios_base::openmode mode); // wide systems only; see 31.10.1

```

Preconditions: `s` points to a NTCTS (3.34).

Effects: If `is_open() != false`, returns a null pointer. Otherwise, initializes the `filebuf` as required. It then opens the file to which `s` resolves, if possible, as if by a call to `fopen` with the second argument determined from `mode` & `~ios_base::ate` as indicated in Table 128. If `mode` is not some combination of flags shown in the table then the open fails.

If the open operation succeeds and `ios_base::ate` is set in `mode`, positions the file to the end (as if by calling `fseek(file, 0, SEEK_END)`, where `file` is the pointer returned by calling `fopen`).³⁰²

If the repositioning operation fails, calls `close()` and returns a null pointer to indicate failure.

Returns: `this` if successful, a null pointer otherwise.

³⁰² The macro `SEEK_END` is defined, and the function signatures `fopen(const char*, const char*)` and `fseek(FILE*, long, int)` are declared, in `<stdio>` (31.13.1).

Table 128 — File open modes [tab:filebuf.open.modes]

binary	ios_base flag combination					stdio equivalent
	in	out	trunc	app	noreplace	
		+				"w"
		+			+	"wx"
		+	+			"w"
		+	+		+	"wx"
		+		+		"a"
				+		"a"
	+					"r"
	+	+				"r+"
	+	+	+			"w+"
	+	+	+		+	"w+x"
	+	+		+		"a+"
	+			+		"a+"
+		+				"wb"
+		+			+	"wbx"
+		+	+			"wb"
+		+	+		+	"wbx"
+		+		+		"ab"
+				+		"ab"
+	+					"rb"
+	+	+				"r+b"
+	+	+	+			"w+b"
+	+	+	+		+	"w+bx"
+	+	+		+		"a+b"
+	+			+		"a+b"

```
basic_filebuf* open(const string& s, ios_base::openmode mode);
basic_filebuf* open(const filesystem::path& s, ios_base::openmode mode);
```

Returns: `open(s.c_str(), mode)`;

```
basic_filebuf* close();
```

Effects: If `is_open() == false`, returns a null pointer. If a put area exists, calls `overflow(trait::eof())` to flush characters. If the last virtual member function called on `*this` (between `underflow`, `overflow`, `seekoff`, and `seekpos`) was `overflow` then calls `a_codecvt.unshift` (possibly several times) to determine a termination sequence, inserts those characters and calls `overflow(trait::eof())` again. Finally, regardless of whether any of the preceding calls fails or throws an exception, the function closes the file (as if by calling `fclose(file)`). If any of the calls made by the function, including `fclose`, fails, `close` fails by returning a null pointer. If one of these calls throws an exception, the exception is caught and rethrown after closing the file.

Postconditions: `is_open() == false`.

Returns: `this` on success, a null pointer otherwise.

31.10.2.5 Overridden virtual functions

[filebuf.virtuals]

```
streamsize showmanyc() override;
```

Effects: Behaves the same as `basic_streambuf::showmanyc()` (31.6.3.5).

Remarks: An implementation may provide an overriding definition for this function signature if it can determine whether more characters can be read from the input sequence.

`int_type underflow() override;`

Effects: Behaves according to the description of `basic_streambuf<charT, traits>::underflow()`, with the specialization that a sequence of characters is read from the input sequence as if by reading from the associated file into an internal buffer (`extern_buf`) and then as if by doing:

```
char    extern_buf[XSIZE];
char*   extern_end;
charT   intern_buf[ISIZE];
charT*  intern_end;
codecvt_base::result r =
    a_codecvt.in(state, extern_buf, extern_buf+XSIZE, extern_end,
                intern_buf, intern_buf+ISIZE, intern_end);
```

This shall be done in such a way that the class can recover the position (`fpos_t`) corresponding to each character between `intern_buf` and `intern_end`. If the value of `r` indicates that `a_codecvt.in()` ran out of space in `intern_buf`, retry with a larger `intern_buf`.

`int_type uflow() override;`

Effects: Behaves according to the description of `basic_streambuf<charT, traits>::uflow()`, with the specialization that a sequence of characters is read from the input with the same method as used by `underflow`.

`int_type pbackfail(int_type c = traits::eof()) override;`

Effects: Puts back the character designated by `c` to the input sequence, if possible, in one of three ways:

- If `traits::eq_int_type(c, traits::eof())` returns `false` and if the function makes a putback position available and if `traits::eq(to_char_type(c), gptr() [-1])` returns `true`, decrements the next pointer for the input sequence, `gptr()`.

Returns: `c`.

- If `traits::eq_int_type(c, traits::eof())` returns `false` and if the function makes a putback position available and if the function is permitted to assign to the putback position, decrements the next pointer for the input sequence, and stores `c` there.

Returns: `c`.

- If `traits::eq_int_type(c, traits::eof())` returns `true`, and if either the input sequence has a putback position available or the function makes a putback position available, decrements the next pointer for the input sequence, `gptr()`.

Returns: `traits::not_eof(c)`.

Returns: As specified above, or `traits::eof()` to indicate failure.

Remarks: If `is_open() == false`, the function always fails.

The function does not put back a character directly to the input sequence.

If the function can succeed in more than one of these ways, it is unspecified which way is chosen. The function can alter the number of putback positions available as a result of any call.

`int_type overflow(int_type c = traits::eof()) override;`

Effects: Behaves according to the description of `basic_streambuf<charT, traits>::overflow(c)`, except that the behavior of “consuming characters” is performed by first converting as if by:

```
charT* b = pbase();
charT* p = pptr();
charT* end;
char    xbuf[XSIZE];
char*   xbuf_end;
codecvt_base::result r =
    a_codecvt.out(state, b, p, end, xbuf, xbuf+XSIZE, xbuf_end);
```

and then

- If `r == codecvt_base::error` then fail.
- If `r == codecvt_base::noconv` then output characters from `b` up to (and not including) `p`.

- If `r == codecvt_base::partial` then output to the file characters from `xbuf` up to `xbuf_end`, and repeat using characters from `end` to `p`. If output fails, fail (without repeating).
- Otherwise output from `xbuf` to `xbuf_end`, and fail if output fails. At this point if `b != p` and `b == end` (`xbuf` isn't large enough) then increase `XSIZE` and repeat from the beginning.

Returns: `traits::not_eof(c)` to indicate success, and `traits::eof()` to indicate failure. If `is_open() == false`, the function always fails.

`basic_streambuf* setbuf(char_type* s, streamsize n) override;`

Effects: If `setbuf(0, 0)` is called on a stream before any I/O has occurred on that stream, the stream becomes unbuffered. Otherwise the results are implementation-defined. “Unbuffered” means that `pbase()` and `pptr()` always return null and output to the file should appear as soon as possible.

`pos_type seekoff(off_type off, ios_base::seekdir way,
ios_base::openmode which
= ios_base::in | ios_base::out) override;`

Effects: Let `width` denote `a_codecvt.encoding()`. If `is_open() == false`, or `off != 0 && width <= 0`, then the positioning operation fails. Otherwise, if `way != basic_ios::cur` or `off != 0`, and if the last operation was output, then update the output sequence and write any unshift sequence. Next, seek to the new position: if `width > 0`, call `fseek(file, width * off, whence)`, otherwise call `fseek(file, 0, whence)`.

Returns: A newly constructed `pos_type` object that stores the resultant stream position, if possible. If the positioning operation fails, or if the object cannot represent the resultant stream position, returns `pos_type(off_type(-1))`.

Remarks: “The last operation was output” means either the last virtual operation was overflow or the put buffer is non-empty. “Write any unshift sequence” means, if `width` is less than zero then call `a_codecvt.unshift(state, xbuf, xbuf+XSIZE, xbuf_end)` and output the resulting unshift sequence. The function determines one of three values for the argument `whence`, of type `int`, as indicated in Table 129.

Table 129 — `seekoff` effects [tab:filebuf.seekoff]

way	Value	stdio Equivalent
<code>basic_ios::beg</code>		<code>SEEK_SET</code>
<code>basic_ios::cur</code>		<code>SEEK_CUR</code>
<code>basic_ios::end</code>		<code>SEEK_END</code>

`pos_type seekpos(pos_type sp,
ios_base::openmode which
= ios_base::in | ios_base::out) override;`

Alters the file position, if possible, to correspond to the position stored in `sp` (as described below). Altering the file position performs as follows:

1. if `(om & ios_base::out) != 0`, then update the output sequence and write any unshift sequence;
2. set the file position to `sp` as if by a call to `fsetpos`;
3. if `(om & ios_base::in) != 0`, then update the input sequence;

where `om` is the open mode passed to the last call to `open()`. The operation fails if `is_open()` returns `false`.

If `sp` is an invalid stream position, or if the function positions neither sequence, the positioning operation fails. If `sp` has not been obtained by a previous successful call to one of the positioning functions (`seekoff` or `seekpos`) on the same file the effects are undefined.

Returns: `sp` on success. Otherwise returns `pos_type(off_type(-1))`.

`int sync() override;`

Effects: If a put area exists, calls `filebuf::overflow` to write the characters to the file, then flushes the file as if by calling `fflush(file)`. If a get area exists, the effect is implementation-defined.

```
void imbue(const locale& loc) override;
```

Preconditions: If the file is not positioned at its beginning and the encoding of the current locale as determined by `a_codecvt.encoding()` is state-dependent (30.4.2.5.3) then that facet is the same as the corresponding facet of `loc`.

Effects: Causes characters inserted or extracted after this call to be converted according to `loc` until another call of `imbue`.

Remarks: This may require reconversion of previously converted characters. This in turn may require the implementation to be able to reconstruct the original contents of the file.

31.10.3 Class template `basic_ifstream`

[ifstream]

31.10.3.1 General

[ifstream.general]

```
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_ifstream : public basic_istream<charT, traits> {
    public:
        using char_type    = charT;
        using int_type      = typename traits::int_type;
        using pos_type      = typename traits::pos_type;
        using off_type      = typename traits::off_type;
        using traits_type   = traits;

        // 31.10.3.2, constructors
        basic_ifstream();
        explicit basic_ifstream(const char* s,
                               ios_base::openmode mode = ios_base::in);
        explicit basic_ifstream(const filesystem::path::value_type* s,
                               ios_base::openmode mode = ios_base::in); // wide systems only; see 31.10.1
        explicit basic_ifstream(const string& s,
                               ios_base::openmode mode = ios_base::in);

        template<class T>
            explicit basic_ifstream(const T& s, ios_base::openmode mode = ios_base::in);
        basic_ifstream(const basic_ifstream&) = delete;
        basic_ifstream(basic_ifstream&& rhs);

        basic_ifstream& operator=(const basic_ifstream&) = delete;
        basic_ifstream& operator=(basic_ifstream&& rhs);

        // 31.10.3.3, swap
        void swap(basic_ifstream& rhs);

        // 31.10.3.4, members
        basic_filebuf<charT, traits>* rdbuf() const;

        bool is_open() const;
        void open(const char* s, ios_base::openmode mode = ios_base::in);
        void open(const filesystem::path::value_type* s,
                 ios_base::openmode mode = ios_base::in); // wide systems only; see 31.10.1
        void open(const string& s, ios_base::openmode mode = ios_base::in);
        void open(const filesystem::path& s, ios_base::openmode mode = ios_base::in);
        void close();

    private:
        basic_filebuf<charT, traits> sb; // exposition only
    };
}
```

The class `basic_ifstream<charT, traits>` supports reading from named files. It uses a `basic_filebuf<charT, traits>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as:

— `sb`, the filebuf object.

31.10.3.2 Constructors

[ifstream.cons]

```
basic_ifstream();
```

Effects: Initializes the base class with `basic_istream<charT, traits>(addressof(sb))` (31.7.5.2.2) and `sb` with `basic_filebuf<charT, traits>()` (31.10.2.2).

```
explicit basic_ifstream(const char* s,
                       ios_base::openmode mode = ios_base::in);
```

```
explicit basic_ifstream(const filesystem::path::value_type* s,
                       ios_base::openmode mode = ios_base::in); // wide systems only; see 31.10.1
```

Effects: Initializes the base class with `basic_istream<charT, traits>(addressof(sb))` (31.7.5.2.2) and `sb` with `basic_filebuf<charT, traits>()` (31.10.2.2), then calls `rdbuf()->open(s, mode | ios_base::in)`. If that function returns a null pointer, calls `setstate(failbit)`.

```
explicit basic_ifstream(const string& s,
                       ios_base::openmode mode = ios_base::in);
```

Effects: Equivalent to: `basic_ifstream(s.c_str(), mode)`.

```
template<class T>
```

```
explicit basic_ifstream(const T& s, ios_base::openmode mode = ios_base::in);
```

Constraints: `is_same_v<T, filesystem::path>` is true.

Effects: Equivalent to: `basic_ifstream(s.c_str(), mode)`.

```
basic_ifstream(basic_ifstream&& rhs);
```

Effects: Move constructs the base class, and the contained `basic_filebuf`. Then calls `basic_istream<charT, traits>::set_rdbuf(addressof(sb))` to install the contained `basic_filebuf`.

31.10.3.3 Swap

[ifstream.swap]

```
void swap(basic_ifstream& rhs);
```

Effects: Exchanges the state of `*this` and `rhs` by calling `basic_istream<charT, traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

```
template<class charT, class traits>
```

```
void swap(basic_ifstream<charT, traits>& x, basic_ifstream<charT, traits>& y);
```

Effects: Equivalent to: `x.swap(y)`.

31.10.3.4 Member functions

[ifstream.members]

```
basic_filebuf<charT, traits>* rdbuf() const;
```

Returns: `const_cast<basic_filebuf<charT, traits>*>(addressof(sb))`.

```
bool is_open() const;
```

Returns: `rdbuf()->is_open()`.

```
void open(const char* s, ios_base::openmode mode = ios_base::in);
```

```
void open(const filesystem::path::value_type* s,
          ios_base::openmode mode = ios_base::in); // wide systems only; see 31.10.1
```

Effects: Calls `rdbuf()->open(s, mode | ios_base::in)`. If that function does not return a null pointer calls `clear()`, otherwise calls `setstate(failbit)` (which may throw `ios_base::failure`) (31.5.4.4).

```
void open(const string& s, ios_base::openmode mode = ios_base::in);
```

```
void open(const filesystem::path& s, ios_base::openmode mode = ios_base::in);
```

Effects: Calls `open(s.c_str(), mode)`.

```
void close();
```

Effects: Calls `rdbuf()->close()` and, if that function returns a null pointer, calls `setstate(failbit)` (which may throw `ios_base::failure`) (31.5.4.4).

31.10.4 Class template `basic_ofstream`

[ofstream]

31.10.4.1 General

[ofstream.general]

```

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_ofstream : public basic_ostream<charT, traits> {
    public:
        using char_type      = charT;
        using int_type        = typename traits::int_type;
        using pos_type        = typename traits::pos_type;
        using off_type        = typename traits::off_type;
        using traits_type     = traits;

        // 31.10.4.2, constructors
        basic_ofstream();
        explicit basic_ofstream(const char* s,
                               ios_base::openmode mode = ios_base::out);
        explicit basic_ofstream(const filesystem::path::value_type* s, // wide systems only; see 31.10.1
                               ios_base::openmode mode = ios_base::out);
        explicit basic_ofstream(const string& s,
                               ios_base::openmode mode = ios_base::out);

        template<class T>
            explicit basic_ofstream(const T& s, ios_base::openmode mode = ios_base::out);
        basic_ofstream(const basic_ofstream&) = delete;
        basic_ofstream(basic_ofstream&& rhs);

        basic_ofstream& operator=(const basic_ofstream&) = delete;
        basic_ofstream& operator=(basic_ofstream&& rhs);

        // 31.10.4.3, swap
        void swap(basic_ofstream& rhs);

        // 31.10.4.4, members
        basic_filebuf<charT, traits>* rdbuf() const;

        bool is_open() const;
        void open(const char* s, ios_base::openmode mode = ios_base::out);
        void open(const filesystem::path::value_type* s,
                 ios_base::openmode mode = ios_base::out); // wide systems only; see 31.10.1
        void open(const string& s, ios_base::openmode mode = ios_base::out);
        void open(const filesystem::path& s, ios_base::openmode mode = ios_base::out);
        void close();

    private:
        basic_filebuf<charT, traits> sb; // exposition only
    };
}

```

The class `basic_ofstream<charT, traits>` supports writing to named files. It uses a `basic_filebuf<charT, traits>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as:

— `sb`, the filebuf object.

31.10.4.2 Constructors

[ofstream.cons]

```
basic_ofstream();
```

Effects: Initializes the base class with `basic_ostream<charT, traits>(addressof(sb))` (31.7.6.2.2) and `sb` with `basic_filebuf<charT, traits>()` (31.10.2.2).

```
explicit basic_ofstream(const char* s,
                       ios_base::openmode mode = ios_base::out);
```

```
explicit basic_ofstream(const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::out); // wide systems only; see 31.10.1
```

Effects: Initializes the base class with `basic_ostream<charT, traits>(addressof(sb))` (31.7.6.2.2) and `sb` with `basic_filebuf<charT, traits>()` (31.10.2.2), then calls `rdbuf()->open(s, mode | ios_base::out)`. If that function returns a null pointer, calls `setstate(failbit)`.

```
explicit basic_ofstream(const string& s,
    ios_base::openmode mode = ios_base::out);
```

Effects: Equivalent to: `basic_ofstream(s.c_str(), mode)`.

```
template<class T>
```

```
explicit basic_ofstream(const T& s, ios_base::openmode mode = ios_base::out);
```

Constraints: `is_same_v<T, filesystem::path>` is true.

Effects: Equivalent to: `basic_ofstream(s.c_str(), mode)`.

```
basic_ofstream(basic_ofstream&& rhs);
```

Effects: Move constructs the base class, and the contained `basic_filebuf`. Then calls `basic_ostream<charT, traits>::set_rdbuf(addressof(sb))` to install the contained `basic_filebuf`.

31.10.4.3 Swap

[ofstream.swap]

```
void swap(basic_ofstream& rhs);
```

Effects: Exchanges the state of `*this` and `rhs` by calling `basic_ostream<charT, traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

```
template<class charT, class traits>
```

```
void swap(basic_ofstream<charT, traits>& x, basic_ofstream<charT, traits>& y);
```

Effects: Equivalent to: `x.swap(y)`.

31.10.4.4 Member functions

[ofstream.members]

```
basic_filebuf<charT, traits>* rdbuf() const;
```

Returns: `const_cast<basic_filebuf<charT, traits>*>(addressof(sb))`.

```
bool is_open() const;
```

Returns: `rdbuf()->is_open()`.

```
void open(const char* s, ios_base::openmode mode = ios_base::out);
```

```
void open(const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::out); // wide systems only; see 31.10.1
```

Effects: Calls `rdbuf()->open(s, mode | ios_base::out)`. If that function does not return a null pointer calls `clear()`, otherwise calls `setstate(failbit)` (which may throw `ios_base::failure`) (31.5.4.4).

```
void close();
```

Effects: Calls `rdbuf()->close()` and, if that function fails (returns a null pointer), calls `setstate(failbit)` (which may throw `ios_base::failure`) (31.5.4.4).

```
void open(const string& s, ios_base::openmode mode = ios_base::out);
```

```
void open(const filesystem::path& s, ios_base::openmode mode = ios_base::out);
```

Effects: Calls `open(s.c_str(), mode)`.

31.10.5 Class template `basic_fstream`

[fstream]

31.10.5.1 General

[fstream.general]

```
namespace std {
```

```
template<class charT, class traits = char_traits<charT>>
```

```
class basic_fstream : public basic_iostream<charT, traits> {
```

```
public:
```

```
using char_type = charT;
```

```

using int_type      = typename traits::int_type;
using pos_type      = typename traits::pos_type;
using off_type      = typename traits::off_type;
using traits_type    = traits;

// 31.10.5.2, constructors
basic_fstream();
explicit basic_fstream(
    const char* s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
explicit basic_fstream(
    const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::in|ios_base::out);    // wide systems only; see 31.10.1
explicit basic_fstream(
    const string& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
template<class T>
    explicit basic_fstream(const T& s, ios_base::openmode mode = ios_base::in | ios_base::out);
basic_fstream(const basic_fstream&) = delete;
basic_fstream(basic_fstream&& rhs);

basic_fstream& operator=(const basic_fstream&) = delete;
basic_fstream& operator=(basic_fstream&& rhs);

// 31.10.5.3, swap
void swap(basic_fstream& rhs);

// 31.10.5.4, members
basic_filebuf<charT, traits>* rdbuf() const;
bool is_open() const;
void open(
    const char* s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
void open(
    const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::in|ios_base::out);    // wide systems only; see 31.10.1
void open(
    const string& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
void open(
    const filesystem::path& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
void close();

private:
    basic_filebuf<charT, traits> sb;    // exposition only
};
}

```

The class template `basic_fstream<charT, traits>` supports reading and writing from named files. It uses a `basic_filebuf<charT, traits>` object to control the associated sequences. For the sake of exposition, the maintained data is presented here as:

— `sb`, the `basic_filebuf` object.

31.10.5.2 Constructors

[fstream.cons]

```
basic_fstream();
```

Effects: Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` (31.7.5.7.2) and `sb` with `basic_filebuf<charT, traits>()`.

```
explicit basic_fstream(
    const char* s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
```

```
explicit basic_fstream(
    const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::in | ios_base::out); // wide systems only; see 31.10.1
```

Effects: Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` (31.7.5.7.2) and `sb` with `basic_filebuf<charT, traits>()`. Then calls `rdbuf()->open(s, mode)`. If that function returns a null pointer, calls `setstate(failbit)`.

```
explicit basic_fstream(
    const string& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
```

Effects: Equivalent to: `basic_fstream(s.c_str(), mode)`.

```
template<class T>
explicit basic_fstream(const T& s, ios_base::openmode mode = ios_base::in | ios_base::out);
```

Constraints: `is_same_v<T, filesystem::path>` is true.

Effects: Equivalent to: `basic_fstream(s.c_str(), mode)`.

```
basic_fstream(basic_fstream&& rhs);
```

Effects: Move constructs the base class, and the contained `basic_filebuf`. Then calls `basic_iostream<charT, traits>::set_rdbuf(addressof(sb))` to install the contained `basic_filebuf`.

31.10.5.3 Swap [fstream.swap]

```
void swap(basic_fstream& rhs);
```

Effects: Exchanges the state of `*this` and `rhs` by calling `basic_iostream<charT, traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

```
template<class charT, class traits>
void swap(basic_fstream<charT, traits>& x,
          basic_fstream<charT, traits>& y);
```

Effects: Equivalent to: `x.swap(y)`.

31.10.5.4 Member functions [fstream.members]

```
basic_filebuf<charT, traits>* rdbuf() const;
```

Returns: `const_cast<basic_filebuf<charT, traits>*>(addressof(sb))`.

```
bool is_open() const;
```

Returns: `rdbuf()->is_open()`.

```
void open(
    const char* s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
void open(
    const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::in | ios_base::out); // wide systems only; see 31.10.1
```

Effects: Calls `rdbuf()->open(s, mode)`. If that function does not return a null pointer calls `clear()`, otherwise calls `setstate(failbit)` (which may throw `ios_base::failure`) (31.5.4.4).

```
void open(
    const string& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
void open(
    const filesystem::path& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
```

Effects: Calls `open(s.c_str(), mode)`.

```
void close();
```

Effects: Calls `rdbuf()->close()` and, if that function returns a null pointer, calls `setstate(failbit)` (which may throw `ios_base::failure`) (31.5.4.4).

31.11 Synchronized output streams

[syncstream]

31.11.1 Header <syncstream> synopsis

[syncstream.syn]

```
#include <ostream> // see 31.7.2

namespace std {
    template<class charT, class traits = char_traits<charT>, class Allocator = allocator<charT>>
        class basic_syncbuf;

    // 31.11.2.6, specialized algorithms
    template<class charT, class traits, class Allocator>
        void swap(basic_syncbuf<charT, traits, Allocator>&,
                  basic_syncbuf<charT, traits, Allocator>&);

    using syncbuf = basic_syncbuf<char>;
    using wsyncbuf = basic_syncbuf<wchar_t>;

    template<class charT, class traits = char_traits<charT>, class Allocator = allocator<charT>>
        class basic_ostream;

    using ostream = basic_ostream<char>;
    using wostream = basic_ostream<wchar_t>;
}
```

The header <syncstream> provides a mechanism to synchronize execution agents writing to the same stream.

31.11.2 Class template basic_syncbuf

[syncstream.syncbuf]

31.11.2.1 Overview

[syncstream.syncbuf.overview]

```
namespace std {
    template<class charT, class traits = char_traits<charT>, class Allocator = allocator<charT>>
        class basic_syncbuf : public basic_streambuf<charT, traits> {
        public:
            using char_type      = charT;
            using int_type       = typename traits::int_type;
            using pos_type       = typename traits::pos_type;
            using off_type       = typename traits::off_type;
            using traits_type    = traits;
            using allocator_type = Allocator;

            using streambuf_type = basic_streambuf<charT, traits>;

            // 31.11.2.2, construction and destruction
            basic_syncbuf()
                : basic_syncbuf(nullptr) {}
            explicit basic_syncbuf(streambuf_type* obuf)
                : basic_syncbuf(obuf, Allocator()) {}
            basic_syncbuf(streambuf_type*, const Allocator&);
            basic_syncbuf(basic_syncbuf&&);
            ~basic_syncbuf();

            // 31.11.2.3, assignment and swap
            basic_syncbuf& operator=(basic_syncbuf&&);
            void swap(basic_syncbuf&);

            // 31.11.2.4, member functions
            bool emit();
            streambuf_type* get_wrapped() const noexcept;
            allocator_type get_allocator() const noexcept;
            void set_emit_on_sync(bool) noexcept;

        protected:
            // 31.11.2.5, overridden virtual functions
            int sync() override;

```

```

private:
    streambuf_type* wrapped;    // exposition only
    bool emit_on_sync{};       // exposition only
};
}

```

Class template `basic_syncbuf` stores character data written to it, known as the associated output, into internal buffers allocated using the object's allocator. The associated output is transferred to the wrapped stream buffer object `*wrapped` when `emit()` is called or when the `basic_syncbuf` object is destroyed. Such transfers are atomic with respect to transfers by other `basic_syncbuf` objects with the same wrapped stream buffer object.

31.11.2.2 Construction and destruction

[syncstream.syncbuf.cons]

```
basic_syncbuf(streambuf_type* obuf, const Allocator& allocator);
```

Effects: Sets `wrapped` to `obuf`.

Postconditions: `get_wrapped() == obuf` and `get_allocator() == allocator` are true.

Throws: Nothing unless an exception is thrown by the construction of a mutex or by memory allocation.

Remarks: A copy of `allocator` is used to allocate memory for internal buffers holding the associated output.

```
basic_syncbuf(basic_syncbuf&& other);
```

Postconditions: The value returned by `this->get_wrapped()` is the value returned by `other.get_wrapped()` prior to calling this constructor. Output stored in `other` prior to calling this constructor will be stored in `*this` afterwards. `other.pbase() == other.pptr()` and `other.get_wrapped() == nullptr` are true.

Remarks: This constructor disassociates `other` from its wrapped stream buffer, ensuring destruction of `other` produces no output.

```
~basic_syncbuf();
```

Effects: Calls `emit()`.

Throws: Nothing. If an exception is thrown from `emit()`, the destructor catches and ignores that exception.

31.11.2.3 Assignment and swap

[syncstream.syncbuf.assign]

```
basic_syncbuf& operator=(basic_syncbuf&& rhs);
```

Effects: Calls `emit()` then move assigns from `rhs`. After the move assignment `*this` has the observable state it would have had if it had been move constructed from `rhs` (31.11.2.2).

Postconditions:

- `rhs.get_wrapped() == nullptr` is true.
- `this->get_allocator() == rhs.get_allocator()` is true when `allocator_traits<Allocator>::propagate_on_container_move_assignment::value` is true; otherwise, the allocator is unchanged.

Returns: `*this`.

Remarks: This assignment operator disassociates `rhs` from its wrapped stream buffer, ensuring destruction of `rhs` produces no output.

```
void swap(basic_syncbuf& other);
```

Preconditions: Either `allocator_traits<Allocator>::propagate_on_container_swap::value` is true or `this->get_allocator() == other.get_allocator()` is true.

Effects: Exchanges the state of `*this` and `other`.

31.11.2.4 Member functions

[syncstream.syncbuf.members]

```
bool emit();
```

Effects: Atomically transfers the associated output of ***this** to the stream buffer ***wrapped**, so that it appears in the output stream as a contiguous sequence of characters. **wrapped->pubsync()** is called if and only if a call was made to **sync()** since the most recent call to **emit()**, if any.

Synchronization: All **emit()** calls transferring characters to the same stream buffer object appear to execute in a total order consistent with the “happens before” relation (6.9.2.2), where each **emit()** call synchronizes with subsequent **emit()** calls in that total order.

Postconditions: On success, the associated output is empty.

Returns: **true** if all of the following conditions hold; otherwise **false**:

- **wrapped == nullptr** is **false**.
- All of the characters in the associated output were successfully transferred.
- The call to **wrapped->pubsync()** (if any) succeeded.

Remarks: May call member functions of **wrapped** while holding a lock uniquely associated with **wrapped**.

```
streambuf_type* get_wrapped() const noexcept;
```

Returns: **wrapped**.

```
allocator_type get_allocator() const noexcept;
```

Returns: A copy of the allocator that was set in the constructor or assignment operator.

```
void set_emit_on_sync(bool b) noexcept;
```

Effects: **emit_on_sync = b**.

31.11.2.5 Overridden virtual functions

[syncstream.syncbuf.virtuals]

```
int sync() override;
```

Effects: Records that the wrapped stream buffer is to be flushed. Then, if **emit_on_sync** is **true**, calls **emit()**.

NOTE If **emit_on_sync** is **false**, the actual flush is delayed until a call to **emit()**.

Returns: If **emit()** was called and returned **false**, returns **-1**; otherwise **0**.

31.11.2.6 Specialized algorithms

[syncstream.syncbuf.special]

```
template<class charT, class traits, class Allocator>
void swap(basic_syncbuf<charT, traits, Allocator>& a,
         basic_syncbuf<charT, traits, Allocator>& b);
```

Effects: Equivalent to **a.swap(b)**.

31.11.3 Class template basic_osyncstream

[syncstream.osyncstream]

31.11.3.1 Overview

[syncstream.osyncstream.overview]

```
namespace std {
    template<class charT, class traits = char_traits<charT>, class Allocator = allocator<charT>>
    class basic_osyncstream : public basic_ostream<charT, traits> {
    public:
        using char_type      = charT;
        using int_type        = typename traits::int_type;
        using pos_type        = typename traits::pos_type;
        using off_type        = typename traits::off_type;
        using traits_type      = traits;

        using allocator_type  = Allocator;
        using streambuf_type  = basic_streambuf<charT, traits>;
        using syncbuf_type    = basic_syncbuf<charT, traits, Allocator>;
```

```

// 31.11.3.2, construction and destruction
basic_osyncstream(streambuf_type*, const Allocator&);
explicit basic_osyncstream(streambuf_type* obuf)
    : basic_osyncstream(obuf, Allocator()) {}
basic_osyncstream(basic_ostream<charT, traits>& os, const Allocator& allocator)
    : basic_osyncstream(os.rdbuf(), allocator) {}
explicit basic_osyncstream(basic_ostream<charT, traits>& os)
    : basic_osyncstream(os, Allocator()) {}
basic_osyncstream(basic_osyncstream&&) noexcept;
~basic_osyncstream();

// assignment
basic_osyncstream& operator=(basic_osyncstream&&);

// 31.11.3.3, member functions
void emit();
streambuf_type* get_wrapped() const noexcept;
syncbuf_type* rdbuf() const noexcept { return const_cast<syncbuf_type*>(addressof(sb)); }

private:
    syncbuf_type sb;    // exposition only
};
}

```

Allocator shall meet the *Cpp17Allocator* requirements (16.4.4.6.1).

EXAMPLE 1 A named variable can be used within a block statement for streaming.

```

{
    ostream bout(cout);
    bout << "Hello, ";
    bout << "World!";
    bout << endl; // flush is noted
    bout << "and more!\n";
} // characters are transferred and cout is flushed

```

EXAMPLE 2 A temporary object can be used for streaming within a single statement.

```
ostream(cout) << "Hello, " << "World!" << '\n';
```

In this example, cout is not flushed.

31.11.3.2 Construction and destruction

[syncstream.osyncstream.cons]

```
basic_osyncstream(streambuf_type* buf, const Allocator& allocator);
```

Effects: Initializes sb from buf and allocator. Initializes the base class with basic_ostream<charT, traits>(addressof(sb)).

NOTE The member functions of the provided stream buffer can be called from emit() while a lock is held, which can result in a deadlock if used incautiously.

Postconditions: get_wrapped() == buf is true.

```
basic_osyncstream(basic_osyncstream&& other) noexcept;
```

Effects: Move constructs the base class and sb from the corresponding subobjects of other, and calls basic_ostream<charT, traits>::set_rdbuf(addressof(sb)).

Postconditions: The value returned by get_wrapped() is the value returned by other.get_wrapped() prior to calling this constructor. nullptr == other.get_wrapped() is true.

31.11.3.3 Member functions

[syncstream.osyncstream.members]

```
void emit();
```

Effects: Behaves as an unformatted output function (31.7.6.4). After constructing a sentry object, calls sb.emit(). If that call returns false, calls setstate(ios_base::badbit).

EXAMPLE 1 A flush on a basic_osyncstream does not flush immediately:

```

{
    ostream bout(cout);

```
