## Foreword

ISO (the International Organization for Standardization) and IEC (the International Electrotechnical Commission) form the specialized system for worldwide standardization. National bodies that are members of ISO or IEC participate in the development of International Standards through technical committees established by the respective organization to deal with particular fields of technical activity. ISO and IEC technical committees collaborate in fields of mutual interest. Other international organizations, governmental and non-governmental, in liaison with ISO and IEC, also take part in the work. In the field of information technology, ISO and IEC have established a joint technical committee, ISO/IEC JTC 1.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of the joint technical committee is to prepare International Standards. Draft International Standards adopted by the joint technical committee are circulated to national bodies for voting. Publication as an International Standard requires approval by at least 75 % of the national bodies casting a vote.

ISO/IEC 9798-5 was prepared by Joint Technical Committee ISO/IEC JTC 1, *Information technology*, Subcommittee SC 27, *IT Security techniques*.

This third edition cancels and replaces the second edition (ISO/IEC 9798-5:2004), which has been technically revised. This edition adds a new mechanism based on elliptic curve discrete logarithm.

ISO/IEC 9798 consists of the following parts, under the general title *Information technology — Security techniques — Entity authentication*:

- *Part 1: General*
- *Part 2: Mechanisms using symmetric encipherment algorithms*
- *Part 3: Mechanisms using digital signature techniques*
- *Part 4: Mechanisms using a cryptographic check function*
- *Part 5: Mechanisms using zero-knowledge techniques*
- *Part 6: Mechanisms using manual data transfer*

## Introduction

This part of ISO/IEC 9798 specifies authentication mechanisms that involve exchanges of information between a claimant and a verifier.

In accordance with the types of calculations that need to be performed by the claimant and the verifier, the mechanisms can be classified into the following four main groups (see Annex C).

- The first group (see Clauses 4 and 5) is characterized by the performance of short modular exponentiations. The challenge size needs to be optimized since it has a proportional impact on workloads.
- The second group (see Clauses 6 and 7 and 8) is characterized by the possibility of a “coupon strategy” for the claimant. A verifier can authenticate a claimant with very limited computational power. The challenge size has no practical impact on workloads.
- The third group (see 9.2) is characterized by the possibility of a coupon strategy for the verifier. A verifier with very limited computational power can authenticate a claimant. The challenge size has no impact on workloads.
- The fourth group (see 9.3) has no possibility of a coupon strategy.

ISO and IEC draw attention to the fact that it is claimed that compliance with this part of ISO/IEC 9798 may involve the use of the following patents and their counterparts in other countries.

US 4 995 082 issued 1991-02-19, Inventor: C.P. Schnorr,

US 5 140 634 issued 1992-08-18, Inventors: L.C. Guillou and J-J. Quisquater,

EP 0 311 470 issued 1992-12-16, Inventors: L.C. Guillou and J-J. Quisquater,

EP 0 666 664 issued 1995-02-02, Inventor: M. Girault,

ISO and IEC take no position concerning the evidence, validity and scope of these patent rights.

The holders of these patent rights have assured ISO and IEC that they are willing to negotiate licenses under reasonable and non-discriminatory terms and conditions with applications throughout the world. In this respect, the statements of the holders of these patent rights are registered with ISO and IEC. Information may be obtained from the companies listed overleaf.

# Information technology — Security techniques — Entity authentication —

## Part 5: Mechanisms using zero-knowledge techniques

### 1 Scope

This part of ISO/IEC 9798 specifies entity authentication mechanisms using zero-knowledge techniques:

- mechanisms based on identities and providing unilateral authentication;
- mechanisms based on integer factorization and providing unilateral authentication;
- mechanisms based on discrete logarithms with respect to numbers that are either prime or composite, and providing unilateral authentication;
- mechanisms based on asymmetric encryption systems and providing either unilateral authentication, or mutual authentication;
- mechanisms based on discrete logarithms on elliptic curves and providing unilateral authentication.

These mechanisms are constructed using the principles of zero-knowledge techniques, but they are not necessarily zero-knowledge according to the strict definition for every choice of parameters.

### 2 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

#### 2.1

##### **accreditation exponent**

secret number related to the verification exponent and used in the production of private keys

#### 2.2

##### **adaptation parameter**

public key specific to the modulus and used in the definition of public keys in the GQ2 mechanisms

#### 2.3

##### **asymmetric cryptographic technique**

cryptographic technique that uses two related operations: a public operation defined by a public data item, and a private operation defined by a private data item (the two operations have the property that, given the public operation, it is computationally infeasible to derive the private operation)

#### 2.4

##### **asymmetric encryption system**

system based on asymmetric cryptographic techniques whose public operation is used for encryption and whose private operation is used for decryption

**2.5**

**asymmetric pair**

two related data items where the private data item defines a private operation and the public data item defines a public operation

**2.6**

**challenge**

procedure parameter used in conjunction with secret parameters to produce a response

**2.7**

**claimant**

entity whose identity can be authenticated, including the functions and the private data necessary to engage in authentication exchanges on behalf of a principal

**2.8**

**coupon**

pair of pre-computed numbers to be used only once; one is kept secret and the other remains secret until its use by an entity

**2.9**

**claimant parameter**

public data item, number or bit string, specific to a given claimant within the domain

**2.10**

**decryption**

reversal of a corresponding encryption

NOTE Decryption<sup>[30]</sup> and decipherment<sup>[24]</sup> are equivalent terms.

**2.11**

**domain**

collection of entities operating under a single security policy

NOTE For example, public key certificates created either by a single certification authority, or by a collection of certification authorities using the same security policy.

**2.12**

**domain parameter**

public key, or function, agreed and used by all entities within the domain

**2.13**

**encryption**

reversible operation by a cryptographic algorithm converting data into ciphertext, so as to hide the information content of the data

NOTE Encryption<sup>[30]</sup> and encipherment<sup>[24]</sup> are equivalent terms.

**2.14**

**entity authentication**

corroboration that an entity is the one claimed

[ISO/IEC 9798-1:1997, definition 3.3.11]

**2.15**

**exchange multiplicity parameter**

number of exchanges of information involved in one instance of an authentication mechanism

**2.16****hash-function**

function that maps strings of bits to fixed-length strings of bits, satisfying the following two properties:

- for a given output, it is computationally infeasible to find an input that maps to this output;
- it is computationally infeasible to find two distinct inputs that map to the same output

[ISO/IEC 10118-1:2000, definition 3.5]

**2.17****identification data**

set of public data items (an account number, an expiry date and time, a serial number, etc.) assigned to an entity and used to identify it

**2.18****mutual authentication**

entity authentication that provides both entities with assurance of each other's identity

[ISO/IEC 9798-1:1997, definition 3.3.14]

**2.19****number**

natural number, i.e. a non-negative integer

**2.20****pair multiplicity parameter**

number of asymmetric pairs of numbers involved in one instance of an authentication mechanism

**2.21****private key**

data item of an asymmetric pair, that shall be kept secret and should only be used by a claimant in accordance with an appropriate response formula, thereby establishing its identity

**2.22****procedure parameter**

transient public data item used in an instance of an authentication mechanism such as a witness, challenge or response

**2.23****public key**

data item of an asymmetric pair, that can be made public and shall be used by every verifier for establishing the claimant's identity

**2.24****random number**

time variant parameter whose value is unpredictable

[ISO/IEC 9798-1:1997, definition 3.3.24]

**2.25****response**

procedure parameter produced by the claimant, and processed by the verifier for checking the identity of the claimant

**2.26****secret parameter**

number or bit string that does not appear in the public domain and is only used by a claimant, e.g. a private key

**2.27**

**token**

message consisting of data fields relevant to a particular communication and which contains information that has been produced using a cryptographic technique

**2.28**

**unilateral authentication**

entity authentication that provides one entity with assurance of the other's identity but not vice versa

[ISO/IEC 9798-1:1997, definition 3.3.33]

**2.29**

**verification exponent**

public key used as exponent by the claimant and the verifier

**2.30**

**verifier**

entity including the functions necessary for engaging in authentication exchanges on behalf of an entity requiring an entity authentication

**2.31**

**witness**

procedure parameter that provides evidence of the claimant's identity to the verifier

**3 Notation, symbols and abbreviated terms**

For the purposes of this document, the following notation, symbols and abbreviated terms apply.

$(a \mid n)$  Jacobi symbol of a positive integer  $a$  with respect to an odd composite integer  $n$

NOTE 1 By definition, the Jacobi symbol of any positive integer  $a$  with respect to any odd positive composite integer  $n$  is the product of the Legendre symbols of  $a$  with respect to each prime factor of  $n$  (repeating the Legendre symbols for the repeated prime factors). The Jacobi symbol <sup>[13][16]</sup> can be efficiently computed without knowledge of the prime factors of  $n$ .

$(a \mid p)$  Legendre symbol of a positive integer  $a$  with respect to an odd prime integer  $p$

NOTE 2 By definition, the Legendre symbol of any positive integer  $a$  with respect to any odd positive prime integer  $p$  is equal to  $a^{(p-1)/2} \pmod p$ . This means that  $(a \mid p)$  is zero if  $a$  is a multiple of  $p$ , and either +1 or -1 otherwise, depending on whether or not  $a$  is a square modulo  $p$ .

$|A|$  bit size of the number  $A$  if  $A$  is a number (i.e. the unique integer  $i$  so that  $2^{i-1} \leq A < 2^i$  if  $A > 0$ , or 0 if  $A = 0$ , e.g.  $|65\ 537| = |2^{16} + 1| = 17$ ), or bit length of the bit string  $A$  if  $A$  is a bit string

NOTE 3 The binary representation of a number  $A$  as a string of  $|A|$  bits is straightforward. To represent a number  $A$  as a string of  $\alpha$  bits with  $\alpha > |A|$ ,  $\alpha - |A|$  bits set to 0 are appended to the left of the  $|A|$  bits.

$\lfloor A \rfloor$  the greatest integer that is less than or equal to the real number  $A$

$B \parallel C$  bit string resulting from the concatenation of data items  $B$  and  $C$  in the order specified. In cases where the result of concatenating two or more data items is input to a cryptographic algorithm as part of an authentication mechanism, this result shall be composed so that it can be uniquely resolved into its constituent data strings, i.e. so that there is no possibility of ambiguity in interpretation. This latter property could be achieved in a variety of different ways, depending on the application. For example, it could be guaranteed by

- (a) fixing the length of each of the substrings throughout the domain of use of the mechanism, or
- (b) encoding the sequence of concatenated strings using a method that guarantees unique decoding, e.g. using the distinguished encoding rules defined in ISO/IEC 8825-1<sup>[23]</sup>

|                      |   |
|----------------------|---|
| CRT                  | Chinese remainder theorem   |
| $d$                  | challenge (procedure parameter)   |
| $D$                  | response (procedure parameter)  |
| $f$                  | number of prime factors   |
| $\text{gcd}(a, b)$   | the greatest common divisor of the two integers $a$ and $b$   |
| $G, G_i$             | public key (domain parameter)   |
| $G(A), G_i(A)$       | public key (claimant parameter)   |
| $h$                  | hash-function   |
| $ h $                | bit length of the hash-code produced by the hash-function $h$   |
| $H, HH$              | hash-codes  |
| $Id(A)$              | identification data (claimant parameter)  |
| $Id_i(A)$            | part of the identification data (claimant parameter)  |
| $j \bmod n$          | the unique integer $i$ from $\{0, 1, \dots, n-1\}$ such that $n$ divides $j - i$  |
| $j \bmod^* n$        | the unique integer $i$ from $\{0, 1, \dots, (n-1)/2\}$ such that $n$ divides either $j - i$ or $j + i$                        |
| $\text{lcm}(a, b)$   | the least common multiple of the two integers $a$ and $b$   |
| $m$                  | pair multiplicity parameter (domain parameter)  |
| $n$                  | composite modulus (domain parameter)  |
| $n(A)$               | composite modulus (claimant parameter)  |
| $p_1, p_2 \dots$     | prime factors of the modulus in ascending order, i.e. $p_1 < p_2 < \dots$ (secret parameters)                                 |
| $Q, Q_i$             | private key (secret parameter)  |
| $r$                  | fresh random number or fresh string of random bits (secret parameter)   |
| $v$                  | verification exponent (domain parameter)  |
| $W$                  | witness (procedure parameter)   |
| $'X_1X_2 \dots'$     | number whose hexadecimal representation is $X_1X_2 \dots$ , where each $X_i$ is equal to one of 0-9 and A-F                   |
| $\alpha$             | modulus size in bits, i.e. $2^{\alpha-1} \leq \text{modulus} < 2^\alpha$ , also denoted $ \text{modulus} $ (domain parameter) |
| $\delta$             | length of fresh strings of random bits for representing challenges (domain parameter)   |
| $\rho$               | length of fresh strings of random bits for representing random numbers (domain parameter)                                     |
| $\{a, b, c, \dots\}$ | set containing the elements $a, b, c, \dots$  |

For the purposes of Clause 5 (identity-based mechanisms), the following symbols and abbreviated terms apply.

- $F$  bit string
- $t$  exchange multiplicity parameter (domain parameter)
- $u$  accreditation exponent with respect to the modulus (secret parameter)
- $u_j$  accreditation exponent with respect to the prime factor  $p_j$  (secret parameter)

For the purposes of Clause 6 (integer factorization based mechanisms), the following symbols and abbreviated terms apply.

- $b$  adaptation parameter (specific to the modulus)
- $D_j$  response component with respect to the prime factor  $p_j$  (secret parameter)
- $g_i$  basic number (domain parameter)
- $g_i(A)$  basic number (claimant parameter)
- $k$  security parameter (domain parameter)
- $Q_{ij}$  private component with respect to the basic number  $g_i$  and the prime factor  $p_j$  (secret parameter)
- $r_j$  fresh random number with respect to the prime factor  $p_j$  (secret parameter)
- $u_j$  accreditation exponent with respect to the prime factor  $p_j$  (secret parameter)
- $W_j$  witness component with respect to the prime factor  $p_j$  (secret parameter)

For the purposes of Clause 7 (mechanisms based on discrete logarithms with respect to prime numbers), the following symbols and abbreviated terms apply.

- $g$  base of the discrete logarithms (domain parameter)
- $p$  modulus (domain parameter)
- $q$  prime number (domain parameter)

For the purposes of Clause 8 (mechanisms based on discrete logarithms with respect to composite numbers), the following symbols and abbreviated terms apply.

- $g$  base of the discrete logarithms (domain parameter)
- $g(A)$  base of the discrete logarithms (claimant parameter)
- $\sigma$  number of bits for private keys in the first mode (domain parameter)

For the purposes of Clause 9 (mechanisms based on asymmetric encryption systems), the following symbols and abbreviated terms apply.

- $P_A$  public operation, i.e. encryption (claimant parameter)
- $S_A$  private operation, i.e. decryption (secret parameter)

For the purposes of Clause 10 (mechanisms based on discrete logarithms on elliptic curves), the following symbols and abbreviated terms apply.

$[n]P$  multiplication operation that takes a positive integer  $n$  and a point  $P$  on the curve  $E$  as input and produces as output another point  $Q$  on the curve  $E$ , where  $Q = [n]P = P + P + \dots + P$  is the sum of  $n$  occurrences of  $P$ . The operation satisfies  $[0]P = 0E$  (the point at infinity), and  $[-n]P = [n](-P)$

## 4 Mechanisms based on identities

### 4.1 Security requirements for the environment

These mechanisms enable a verifier to check that a claimant knows private key(s) that are related to identification data by a verification key.

NOTE These mechanisms implement schemes due either to Fiat and Shamir<sup>[4]</sup> and denoted FS, or to Guillou and Quisquater<sup>[11]</sup> and denoted GQ1.

Within a given domain, the following requirements shall be satisfied.

1) Domain parameters shall be selected, which will govern the operation of the mechanism. They include a hash-function, e.g. one of the functions specified in ISO/IEC 10118-3<sup>[25]</sup>. The selected parameters shall be made known in a reliable manner to all entities within the domain.

2) Every claimant shall be equipped with a modulus that is either a domain parameter or a claimant parameter. Each number used as modulus is set equal to the product of two or more distinct prime factors so that knowledge of its value shall not feasibly enable any entity to deduce its prime factors, where feasibility is defined by the context of use of the mechanism.

— If the modulus is a domain parameter, then it is denoted  $n$ . A trusted authority has selected it and only this authority can use the corresponding prime factors. The authority guarantees the identities of every claimant within the domain.

NOTE 1 For example, a card issuer has a modulus. A delegated entity signs identification data for issuing smart cards; it uses the issuer's prime factors. In each card, the delegated entity stores appropriate identification data and private key(s). During its life, the card uses its private key(s) in accordance with an identity-based mechanism.

— If the modulus is a claimant parameter, then it is denoted  $n(A)$ . A principal has selected it and the corresponding prime factors are the principal's long-term secret. For each session, the principal creates a claimant. The claimant uses private key(s) as a short-term secret.

NOTE 2 For example, in a local area network, an authority supervises each login operation within the domain and manages a directory where every verifier can obtain a trusted copy of a modulus for each principal.

— During each login operation, i.e. when a computer opens a session, it uses a principal's prime factors for a "single-sign-on" of session identification data including identifier, expiry date and time, rights, etc.

During the session, the computer cannot use the prime factors because it does not know them any more. It uses the private key(s) in accordance with an identity-based mechanism. The private keys only last for a few hours: their utility disappears after the session.

3) Every claimant shall be provided with identification data and with one or more private keys by some means. In this context, the identification data is a string of bits, not all equal, that uniquely and meaningfully identifies the claimant in accordance with an agreed convention.

NOTE The presence of an expiry date and time in the identification data enforces their expiry; the presence of a serial number simplifies their revocation.

4) Every verifier shall obtain a trusted copy of the correct modulus of the claimant.

NOTE The exact means by which the verifier obtains a trusted copy of the correct modulus is beyond the scope of this part of ISO/IEC 9798. This may, for example, be achieved by the use of public-key certificates or by some other environment-dependent means.

5) Every claimant and every verifier shall have the means to produce random numbers.

## 4.2 Key production

### 4.2.1 Asymmetric key pair

A verification exponent, a pair multiplicity parameter and an exchange multiplicity parameter shall be selected. Unless otherwise specified, they are domain parameters respectively denoted  $v$ ,  $m$  and  $t$ .

- Certain values of  $v$ , such as the prime numbers 2, 257,  $2^{16}+1$ ,  $2^{32}+15$ ,  $2^{36}+2^{13}+1$  and  $2^{40}+15$ , have some practical advantages.
- The value of  $m$  shall be at most eight if  $v = 2$  and set equal to one if  $v$  is an odd prime.
- The value of  $v^{-m \times t}$  fixes a mechanism security level (see C.1.4). A value from  $2^{-8}$  to  $2^{-40}$  is appropriate for most applications.

A number, denoted  $\alpha$ , fixes the modulus size in bits, i.e.  $2^{\alpha-1} < \text{modulus} < 2^\alpha$ , in accordance with the context of use of the mechanism (for further details, see C.1.1). It is a domain parameter.

The authority or the principal shall keep secret two or more distinct large prime factors denoted  $p_1, p_2 \dots$  in ascending order, the product of which is the modulus.

- If  $v = 2$  (the Rabin scheme), there shall be only two prime factors (i.e.  $f = 2$ ), both congruent to 3 mod 4, but not congruent to each other mod 8.
- If  $v$  is an odd prime (the RSA scheme), there may be more than two prime factors. For each prime factor  $p_j$ ,  $p_j - 1$  shall be co-prime to  $v$ .

If  $\alpha$  is a multiple of the number of prime factors, denoted  $f$ , then the bit size of each prime factor shall be  $\alpha / f$  (for further details, see C.1.2). The modulus is set equal to either  $p_1 \times p_2$  if  $v = 2$ , or  $p_1 \times \dots \times p_f$  if  $v$  is odd. In accordance with the second requirement in 5.1, the modulus is either a domain parameter denoted  $n$ , or a claimant parameter denoted  $n(A)$ .

With respect to each prime factor  $p_j$ , an accreditation exponent, denoted  $u_j$ , is set equal to the least positive integer so that  $u_j \times v + 1$  is a multiple of either  $(p_j - 1)/2$  if  $v = 2$ , or  $p_j - 1$  if  $v$  is an odd prime.

With respect to the modulus, an accreditation exponent, denoted  $u$ , is set equal to the least positive integer so that  $u \times v + 1$  is a multiple of either  $\text{lcm}(p_1 - 1, p_2 - 1)/2$  if  $v = 2$ , or  $\text{lcm}(p_1 - 1, \dots, p_f - 1)$  if  $v$  is an odd prime.

### 4.2.2 Asymmetric pair(s) of numbers

#### 4.2.2.1 Case where $v = 2$

The identification data  $Id(A)$  shall be converted into  $m$  parts by appending sixteen bits representing the numbers 1 to  $m$ , namely '0001', '0002', and so on, in turn to the string  $Id(A)$ .

$$Id_x(A) = Id(A) \parallel '000X'$$

NOTE The mechanism below derives from the first format mechanism specified in ISO/IEC 14888-2<sup>[27]</sup>, known as PSS (PSS reads Probabilistic Signature Scheme) and due to Bellare and Rogaway<sup>[1]</sup>.

For converting each part, from  $Id_1(A)$  to  $Id_m(A)$ , into a string of  $\alpha$  bits, denoted  $F_1$  to  $F_m$ , the following computational steps are performed.

- 1) The string  $Id_x(A)$  shall be hashed to obtain a hash-code denoted  $H_x$ .

$$H_x = h(Id_x(A))$$

- 2) A string of  $(64 + |h|)$  bits is constructed from left to right by concatenating 8 octets set to '00' and the hash-code  $H_x$ . This string shall be hashed to obtain a hash-code denoted  $HH_x$ .

$$HH_x = h('00000000 00000000' \parallel H_x)$$

- 3) A mask comprising a string of  $(\alpha - |h| - 8)$  bits is constructed from the hash-code  $HH_x$ . The procedure makes use of two variables: a bit string of variable length, denoted *String*, and a 32-bit counter, denoted *Counter*.
- Set *String* to the empty string.
  - Set *Counter* to 0.
  - Replace *String* by *String* ||  $h(HH_x || \text{Counter})$ .
  - Replace *Counter* by *Counter* + 1.
  - If  $|h| \times \text{Counter} < \alpha - |h| - 8$ , then go to step c.

$Mask_x$  equals the leftmost  $(\alpha - |h| - 8)$  bits of *String* where the leftmost bit has been forced to 0.

- 4) A string denoted  $F_x$  is constructed from left to right by concatenating the  $(\alpha - |h| - 8)$  bits of the mask where the rightmost bit has been reversed, the  $|h|$  bits of the hash-code  $HH_x$  and one octet set to 'BC'.

$$F_x = \text{Format}(Id_x(A)) = (Mask_x \oplus (000 \dots 000 || 1)) || HH_x || \text{'BC'}$$

A public key denoted  $G_x(A)$  is derived from the number represented by the bit string  $F_x$  (also denoted  $F_x$ , this number is even, non-zero and less than the modulus), as follows.

- If the Jacobi symbol  $(F_x | n)$  is +1, then  $G_x(A) = F_x$ .
- If the Jacobi symbol  $(F_x | n)$  is -1, then  $G_x(A) = F_x / 2$ .

The authority or the principal shall provide claimant *A* with  $m$  private keys denoted  $Q_1$  to  $Q_m$ . The private key denoted  $Q_x$  is set equal to the  $u$ -th modular power of the public key  $G_x(A)$ .

$$Q_x = G_x(A)^u \pmod{\text{either } n \text{ or } n(A)}$$

NOTE 1 The CRT technique (see C.2.3) may be used for converting each public key into a private key.

— For each prime factor  $p_j$ , a component  $Z_j$  is set equal to  $G_x(A)^{u_j} \pmod{p_j}$ .

— A CRT composition converts the set of components  $\{Z_1, Z_2 \dots\}$  into a number  $Z$ .

$$Q_x = Z \pmod{\text{either } n \text{ or } n(A)}$$

NOTE 2 Each asymmetric pair of numbers verifies a relationship governed by the verification key.

$$G_x(A) \times Q_x^2 \equiv 1 \pmod{\text{either } n \text{ or } n(A)}$$

NOTE 3 Consequently, any number  $G_x(A)$  or  $Q_x$  may be replaced by the modulus minus the number.

#### 4.2.2.2 Case where $v$ is an odd prime

NOTE The mechanism below derives from the first format mechanism specified in ISO/IEC 14888-2<sup>[27]</sup>, known as PSS (PSS reads Probabilistic Signature Scheme) and due to Bellare and Rogaway<sup>[1]</sup>.

For converting the identification data  $Id(A)$  into a string of  $\alpha$  bits, denoted  $F$ , the following computational steps are performed.

- 1) The string  $Id(A)$  shall be hashed to obtain a hash-code denoted  $H$ .

$$H = h(Id(A))$$

- 2) A string of  $(64 + |h|)$  bits is constructed from left to right by concatenating 8 octets set to '00' and the hash-code  $H$ . This string shall be hashed to obtain a hash-code denoted  $HH$ .

$$HH = h('00000000 00000000' || H)$$

- 3) A mask comprising a string of  $(\alpha - |h|)$  bits is constructed from the hash-code  $HH$ . The procedure makes use of two variables: a bit string of variable length, denoted *String*, and a 32-bit counter, denoted *Counter*.

- Set *String* to the empty string.
- Set *Counter* to 0.
- Replace *String* by *String* ||  $h(HH || \text{Counter})$ .

- d) Replace *Counter* by *Counter* + 1.
- e) If  $|h| \times \text{Counter} < \alpha - |h|$ , then go to step c.

The mask equals the leftmost  $(\alpha - |h|)$  bits of *String* where the leftmost bit has been forced to 0.

- 4) A string denoted *F* is constructed from left to right by concatenating the  $(\alpha - |h|)$  bits of the mask where the rightmost bit has been reversed and the  $|h|$  bits of the hash-code *HH*.

$$F = \text{Format}(Id(A)) = (\text{Mask} \oplus (000 \dots 000 \parallel 1)) \parallel HH$$

A public key, denoted  $G(A)$ , is set equal to the number represented by the bit string *F* (also denoted *F*, this number is non-zero and less than the modulus).

$$G(A) = F$$

The authority or the principal shall provide claimant *A* with a private key, denoted *Q*, set equal to the *u*-th modular power of the public key  $G(A)$ .

$$Q = G(A)^u \pmod{\text{either } n \text{ or } n(A)}$$

NOTE 1 The CRT technique (see C.2.3) may be used for converting the public key into the private key.

- For each prime factor  $p_j$ , a component  $Q_j$  is set equal to  $G(A)^{u_j} \pmod{p_j}$ .
- A CRT composition converts the set of components  $\{Q_1, Q_2 \dots\}$  into the number *Q*.

NOTE 2 The asymmetric pair of numbers (the private key is the modular inverse of the RSA signature, see ISO/IEC 14888-2<sup>[27]</sup>) verifies a relationship governed by the verification key.

$$G(A) \times Q^v \equiv 1 \pmod{\text{either } n \text{ or } n(A)}$$

### 4.3 Unilateral authentication exchange

The bracketed numbers in Figure 1 correspond to the steps of the mechanism, including the exchanges of information, described in detail below. The claimant is denoted *A*. The verifier is denoted *B*.

Figure 1 — Identity-based mechanism

In addition to identification data  $Id(A)$ , a verification exponent  $v$  (a prime number), a pair multiplicity parameter  $m$  and an exchange multiplicity parameter  $t$ , the claimant shall store a modulus  $n$  or  $n(A)$  and either

- $m$  private keys  $Q_1$  to  $Q_m$  if  $v = 2$ , or
- a single private key  $Q$  if  $v$  is an odd prime.

In addition to identification data  $Id(A)$ , a verification exponent  $v$  (a prime number), a pair multiplicity parameter  $m$  and an exchange multiplicity parameter  $t$ , the verifier shall be provided with a trusted copy of a modulus  $n$  or  $n(A)$ . If not already known by *B*, a copy of  $Id(A)$ ,  $v$ ,  $m$  and  $t$  shall be sent along with  $\text{TokenAB}_1$ ; however, such a copy needs not be trusted.

For each application of the mechanism, the following procedure shall be performed  $t$  times. The verifier *B* shall only accept the claimant *A* as valid if all  $t$  iterations of the procedure complete successfully.

- 1) For each iteration of the procedure, a fresh number shall be uniformly selected at random, so that it is non-zero and less than the modulus. Denoted  $r$ , it shall be kept secret.

The fresh random number  $r$  shall be converted into a witness, denoted  $W$ , as the  $v$ -th modular power.

- Witness formula if  $v = 2$ :  $W = r^2 \pmod{\text{either } n \text{ or } n(A)}$
- Witness formula if  $v$  is an odd prime:  $W = r^v \pmod{\text{either } n \text{ or } n(A)}$

The number  $W$  is represented by a string of  $\alpha$  bits, also denoted  $W$ .

- 2)  $A$  sends  $\text{TokenAB}_1$  to  $B$ .  $\text{TokenAB}_1$  is either witness  $W$  or a hash-code of  $W$  and  $\text{Text}$ , one of the following four hash variants.

The four hash variants are  $h(W \parallel \text{Text})$ ,  $h(W \parallel h(\text{Text}))$ ,  $h(h(W) \parallel \text{Text})$ , and  $h(h(W) \parallel h(\text{Text}))$ , where  $h$  is a hash-function and  $\text{Text}$  is an optional text field (it may be empty). If the text field is non-empty, then  $B$  shall have the means to recover the value of  $\text{Text}$ ; this may require  $A$  to send all or part of the text field at this point. The text field is available for use in applications outside the scope of this part of ISO/IEC 9798. Annex A of ISO/IEC 9798-1<sup>[24]</sup> gives information on the use of text fields. The hash variant is a domain parameter.

- 3) On receipt of  $\text{TokenAB}_1$ , the following computational steps are performed.
- a) If the value of  $v^{m \times t}$  is less than  $2^{40}$  and/or if  $m > 8$  when  $v = 2$ , and/or if  $m > 1$  when  $v$  is an odd prime, then the procedure fails.
  - b) If the identification data  $Id(A)$  is invalid (e.g. expired or revoked), then the procedure fails.
  - c) A fresh string of  $\delta$  bits shall be uniformly selected at random.
    - If  $v = 2$ , then  $\delta = m$  and the string consists of  $m$  bits, denoted  $d_1$  to  $d_m$ .
    - If  $v$  is an odd prime, then  $\delta = |v| - 1$  and the string represents a number less than  $v$ , possibly zero, denoted  $d$ .

NOTE The total number of possible challenges per iteration of the procedure should be limited to  $2^{40}$ . If this recommendation is not followed, then special care should be taken to prevent the verifier using the claimant as a signing oracle.

- 4)  $B$  sends the fresh string as a challenge to  $A$ .

NOTE Optimizations may induce constraints on the Hamming weight of the challenges, with an impact on the total number of possible challenges and on the mechanism security level.

- 5) On receipt of the challenge, the following computational steps are performed.

- a) If the challenge is not a string of  $\delta$  bits, then the procedure fails.
- b) A response denoted  $D$  shall be computed from the random number  $r$  and
  - the  $m$  private keys  $Q_1, Q_2, \dots, Q_m$  and the  $m$  challenge bits  $d_1, d_2, \dots, d_m$  if  $v = 2$ .

$$\text{Response formula if } v = 2: \quad D = r \times \prod_{i=1}^m Q_i^{d_i} \pmod{\text{either } n \text{ or } n(A)}$$

- the single private key  $Q$  and the challenge number  $d$  if  $v$  is an odd prime.

$$\text{Response formula if } v \text{ is an odd prime: } \quad D = r \times Q^d \pmod{\text{either } n \text{ or } n(A)}$$

- 6)  $A$  sends  $\text{TokenAB}_2$  to  $B$ .  $\text{TokenAB}_2$  is the response  $D$  computed from step 5)b).

- 7) On receipt of  $\text{TokenAB}_2$ , the following computational steps are performed.

- a) If the response  $D$  is **zero** or equal to or more than the modulus, then the procedure fails.
- b) The identification data  $Id(A)$  shall be converted into
  - $m$  public keys (see 5.2.2.1), denoted  $G_1(A), G_2(A), \dots, G_m(A)$ , if  $v = 2$ .
  - a single public key (see 5.2.2.2), denoted  $G(A)$ , if  $v$  is an odd prime.

c) Denoted  $W^*$ , a witness shall be computed.

- Verification formula if  $v = 2$ : 
$$W^* = D^2 \times \prod_{i=1}^m G_i(A)^{d_i} \pmod{\text{either } n \text{ or } n(A)}$$
- Verification formula if  $v$  is an odd prime: 
$$W^* = D^v \times G(A)^d \pmod{\text{either } n \text{ or } n(A)}$$

d) If either witness  $W^*$  or a hash-code of  $W^*$  and  $Text$ , one of the four hash variants, is identical to  $TokenAB_1$  received in step (2), then the iteration of the procedure is successful. Otherwise the procedure fails.

NOTE 1 Other information may be sent with any exchange of the procedure.  $B$  might use such information to help compute the value of the optional text field.

NOTE 2  $B$  can compute the public key(s) for  $A$  at any stage, i.e.  $B$  need not wait until the receipt of response  $D$  before computing them. If  $B$  verifies  $A$  frequently, then  $B$  may cache the public key(s).

NOTE 3 The  $t$  iterations of the procedure can be performed in parallel, i.e. in the first step,  $A$  may choose  $t$  random numbers  $r_1, r_2, \dots, r_t$ , compute  $t$  witnesses  $W_1, W_2, \dots, W_t$ , send them simultaneously to  $B$ , and so on. If this parallel implementation is adopted, the total number of message exchanges will be equal to three, regardless of the value of  $t$ .

NOTE 4 The use of a hash-code instead of witness  $W$  in the first exchange of the procedure can achieve efficiency gains by reducing the number of bits in  $TokenAB_1$ .

## 5 Mechanisms based on integer factorization

### 5.1 Security requirements for the environment

These mechanisms enable a verifier to check that a claimant knows a decomposition of a claimed modulus.

NOTE These mechanisms implement schemes due to Guillou and Quisquater<sup>[12]</sup> and denoted GQ2.

Within a given domain, the following requirements shall be satisfied.

- 1) Domain parameters shall be selected, which will govern the operation of the mechanism. The selected parameters shall be made known in a reliable manner to all entities within the domain.
- 2) Every claimant shall be equipped with distinct prime factors so that knowledge of their product, i.e. the modulus (a claimant parameter), shall not feasibly enable any entity to deduce them, where feasibility is defined by the context of use of the mechanism.

NOTE When opening a session (see 5.1), a computer may randomly select two prime factors to be used during the session (a few hours). Using the principal's long-term secret in a "single-sign-on" of session identification data, the computer signs an "ephemeral" certificate covering an "ephemeral" modulus, product of the "ephemeral" prime factors.

- 3) Every verifier shall obtain a trusted copy of the modulus specific to the claimant.

NOTE The exact means by which the verifier obtains a trusted copy of the modulus specific to the claimant is beyond the scope of this part of ISO/IEC 9798. This may, for example, be achieved by the use of public-key certificates or by some other environment-dependent means.

- 4) Every claimant and every verifier shall have the means to produce random numbers.
- 5) If the mechanism makes use of a hash-function, then all entities within the domain shall agree on a hash-function, e.g. one of the functions specified in ISO/IEC 10118-3<sup>[25]</sup>.

### 5.2 Key production

A number, denoted  $\alpha$ , fixes the modulus size in bits, i.e.  $2^{\alpha-1} < \text{modulus} < 2^\alpha$ , in accordance with the context of use of the mechanism (for further details, see C.1.1). It is a domain parameter.

A security parameter and a pair multiplicity parameter, denoted  $k$  and  $m$ , together fix a mechanism security level set to the value of  $2^{-k \times m}$  in accordance with the needs of the application (see C.1.4). They are domain parameters. A value of  $k \times m$  from 8 to 40 is appropriate for most applications.

NOTE 1 The total number of possible challenges should be limited to  $2^{40}$ . If this recommendation is not followed, then special care should be taken to prevent the verifier using the claimant as a signing oracle.

Claimant *A* shall keep secret two or more distinct large prime factors denoted  $p_1, p_2 \dots$  in ascending order. If  $\alpha$  is a multiple of the number of prime factors, denoted  $f$ , then the bit size of each prime factor shall be  $\alpha / f$  (for further details, see C.1.2).

Each prime factor  $p_j$  determines a number, denoted  $b_j$ , so that  $p_j - 1$  is divisible by  $2^{b_j}$ , but not by  $2^{b_j+1}$ , i.e. the  $b_j+1$  least significant bits of  $p_j - 1$  are one bit set to 1 followed by  $b_j$  bits set to 0 and  $(p_j - 1)/2^{b_j}$  is an odd number.

NOTE 2 The number  $b_j$  is set equal to one if  $p_j \equiv 3 \pmod{4}$ , and to two or more if  $p_j \equiv 1 \pmod{4}$ .

For the equivalence with a decomposition of the modulus, the first 54 prime numbers, namely {2, 3, 5, 7, 11, ... 251}, i.e. of bit size equal to eight or less, are searched for an appropriate number  $g$ .

— The Legendre symbol of a candidate number  $g$  is evaluated with respect to each prime factor from  $p_1$  to  $p_f$ . The candidate number  $g$  is appropriate if there are two prime factors  $p_j$  and  $p_i$  as follows.

- If  $b_j = b_i$ , the Legendre symbols are different, i.e.  $(g | p_j) = - (g | p_i)$ .
- If  $b_j > b_i$ , the Legendre symbol with respect to  $p_j$  is  $-1$ , i.e.  $(g | p_j) = -1$ .

NOTE 3 In average, each candidate number has one chance out of  $2^{f-1}$  of being appropriate. Consequently the probability is negligible of not finding an appropriate number  $g$  within the first 54 prime numbers.

The  $m$  basic numbers are the number  $g$ , completed by as many numbers as needed from the first 54 prime numbers. They are either domain parameters, denoted  $g_1$  to  $g_m$  in ascending order if they are the first  $m$  prime numbers, or claimant parameters, denoted  $g_1(A)$  to  $g_m(A)$  in ascending order otherwise.

NOTE 4 If the  $m$  basic numbers are systematically the first  $m$  prime numbers without checking the Legendre symbols, then for  $f$  large prime factors randomly generated, the probability that the knowledge of the set of the private keys does not imply the knowledge of a decomposition of the modulus is in average less than  $2^{-m \times (f-1)}$ .

An adaptation parameter denoted  $b$  is set equal to  $\max(b_1 \text{ to } b_f)$ . It is a claimant parameter. For each basic number  $g_i$  or  $g_i(A)$ , a public key denoted  $G_i$  is set equal to the  $b$ -th square of the basic number.

$$G_i = \text{Either } g_i^{2^b} \text{ or } g_i(A)^{2^b}$$

A verification exponent denoted  $v$  is set equal to  $2^{k+b}$ . With respect to each prime factor  $p_j$ , an accreditation exponent, denoted  $u_j$ , is set equal to the least positive integer so that  $v \times u_j + 1$  is a multiple of  $(p_j - 1)/2^{b_j}$ .

For each basic number  $g_i$  or  $g_i(A)$  and each prime factor  $p_j$ , a private component denoted  $Q_{i,j}$  is set equal to the  $u_j$ -th modular power of the public key  $G_i$ .

$$Q_{i,j} = G_i^{u_j} \pmod{p_j}$$

The modulus is set equal to the product of the large prime factors, i.e.  $p_1 \times \dots \times p_f$ . It is a claimant parameter denoted  $n(A)$ .

NOTE 5 The same modulus may be used for the GQ2 mechanisms and for the RSA mechanisms.

### 5.3 Unilateral authentication exchange

The bracketed numbers in Figure 2 correspond to the steps of the mechanism, including the exchanges of information, described in detail below. The claimant is denoted *A*. The verifier is denoted *B*.

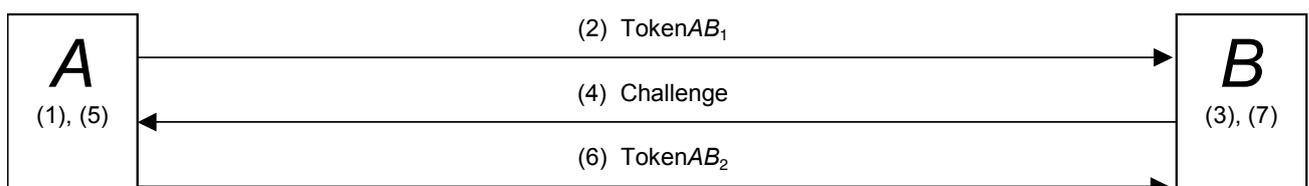

Figure 2 — Mechanism based on the factorization of a modulus

In addition to parameters  $b$ ,  $k$  and  $m$ , and  $m$  basic numbers  $g_1$  to  $g_m$  or  $g_1(A)$  to  $g_m(A)$ , the claimant shall store either

- a modulus  $n(A)$  and  $m$  private keys  $Q_1$  to  $Q_m$ , or
- $f$  prime factors  $p_1$  to  $p_f$ ,  $f \times m$  private components  $Q_{1,1}$  to  $Q_{m,f}$  and  $(f-1)$  CRT coefficients (see C.2.3).

In addition to parameters  $b$ ,  $k$  and  $m$ , and  $m$  basic numbers  $g_1$  to  $g_m$  or  $g_1(A)$  to  $g_m(A)$ , the verifier shall be provided with a trusted copy of the claimant's modulus  $n(A)$ . If not already known by  $B$ , a copy of  $b$ ,  $k$ ,  $m$  and  $g_1(A)$  to  $g_m(A)$  shall be sent along with  $\text{TokenAB}_1$ ; however, such a copy needs not be trusted.

For each application of the mechanism, the following procedure shall be performed. The verifier  $B$  shall only accept the claimant  $A$  as valid if the procedure completes successfully.

- 1) For each iteration of the procedure, for each prime factor  $p_j$ , a fresh number shall be uniformly selected at random, non-zero and less than  $p_j$ . Denoted  $r_j$ , it shall be kept secret.

Each fresh random  $r_j$  number shall be converted into a witness component, denoted  $W_j$ .

Witness component formula: 
$$W_j = r_j^v \text{ mod } p_j$$

Involving the set of prime factors and CRT coefficient(s), a CRT composition (see C.2.3) shall convert the set of witness components  $\{W_1, W_2, \dots\}$  into a witness denoted  $W$ . The number  $W$  is represented by a string of  $\alpha$  bits, also denoted  $W$ .

- 2)  $A$  sends  $\text{TokenAB}_1$  to  $B$ .  $\text{TokenAB}_1$  is either witness  $W$  or a hash-code of  $W$  and  $\text{Text}$ , one of the following four hash variants.

The four hash variants are  $h(W \parallel \text{Text})$ ,  $h(W \parallel h(\text{Text}))$ ,  $h(h(W) \parallel \text{Text})$ , and  $h(h(W) \parallel h(\text{Text}))$ , where  $h$  is a hash-function and  $\text{Text}$  is an optional text field (it may be empty). If the text field is non-empty, then  $B$  shall have the means to recover the value of  $\text{Text}$ ; this may require  $A$  to send all or part of the text field at this point. The text field is available for use in applications outside the scope of this part of ISO/IEC 9798. Annex A of ISO/IEC 9798-1 [24] gives information on the use of text fields. The hash variant is a domain parameter.

- 3) On receipt of  $\text{TokenAB}_1$ , the following computational steps are performed.
  - a) If the product  $k \times m$  is more than 40, then the procedure fails.
  - b) If the basic numbers are not distinct prime numbers less than 256, then the procedure fails.
  - c) A fresh string of  $k \times m$  bits shall be uniformly selected at random and denoted  $d_{1,1}$  to  $d_{m,k}$ .
- 4)  $B$  sends the fresh string as a challenge to  $A$ .

NOTE Optimizations may limit the Hamming weight of the challenges, with an impact on the total number of possible challenges and on the mechanism security level.

- 5) On receipt of the challenge, the following computational steps are performed.
  - a) If the challenge is not a string of  $k \times m$  bits, then the procedure fails.
  - b) For each prime factor  $p_j$ , a component  $D_j$  shall be computed from the challenge denoted  $d_{1,1}$  to  $d_{m,k}$ , the  $m$  private components  $Q_{1,j}$  to  $Q_{m,j}$  and the random number  $r_j$ .

Starting from a number set equal to one,  $k$  sequences of zero to  $m$  modular multiplications are interleaved with  $k-1$  modular squares. The  $ii$ -th sequence is as follows: for  $i$  from 1 to  $m$ , the bit  $d_{i,ii}$  indicates whether the current number shall be modularly multiplied by the private component  $Q_{i,j}$  (bit set to 1) or not (bit set to 0). A last modular multiplication by the random number  $r_j$  produces a final number, namely a response component denoted  $D_j$ .

Consequently, considering that, from bit  $d_{i,1}$  as the most significant bit up to bit  $d_{i,k}$  as the least significant bit, each string of  $k$  bits represents a number less than  $2^k$ , possibly zero, denoted  $d_i$ , the response component formula reads as follows.

$$D_j = r_j \times \prod_{i=1}^m Q_{i,j}^{d_i} \text{ mod } p_j$$

Involving the set of prime factors and the CRT coefficient(s), a CRT composition (see C.2.3) shall convert the set of response components  $\{D_1, D_2, \dots\}$  into a response denoted  $D$ .

- 6)  $A$  sends  $\text{TokenAB}_2$  to  $B$ .  $\text{TokenAB}_2$  is the response  $D$  computed from step 5)b).

- 7) On receipt of  $\text{TokenAB}_2$ , the following computational steps are performed.
- If the response  $D$  is zero or equal to or more than  $n(A)$ , then the procedure fails.
  - The response  $D$  shall be converted into a witness denoted  $W^*$ .

Starting from a number set equal to  $D$ ,  $(b + k)$  modular squares are interleaved with  $k$  elementary operations. The  $ii$ -th elementary operation occurs between the  $ii$ -th and the  $(ii + 1)$ -th modular squares. The  $ii$ -th elementary operation is as follows: for  $i$  from 1 to  $m$ , the bit  $d_{i,ii}$  states whether the current number shall be modularly multiplied by the basic number  $g_i$  (bit set to 1) or not (bit set to 0).

Consequently, considering that, from bit  $d_{i,1}$  as the most significant bit up to bit  $d_{i,k}$  as the least significant bit, each string of  $k$  bits represents a number less than  $2^k$ , possibly zero, denoted  $d_i$ , the verification formula reads as follows.

$$W^* = D^v \times \prod_{i=1}^m G_i^{d_i} \pmod{n(A)}$$

- If either witness  $W^*$  or a hash-code of  $W^*$  and  $\text{Text}$ , one of the four hash variants, is identical to  $\text{TokenAB}_1$  received in step (2), then the procedure is successful. Otherwise the procedure fails.

NOTE 1 Other information may be sent with any exchange of the procedure.  $B$  may use such information to help compute the value of the optional text field. For example,  $A$  may send information such as certificates with  $\text{TokenAB}_1$ .

NOTE 2 For computing the witness and the response, the CRT technique (see C.2.3) is optional.

NOTE 3 The use of a hash-code instead of witness  $W$  in the first exchange of the procedure can achieve efficiency gains by reducing the number of bits in  $\text{TokenAB}_1$ . Moreover, this deters fault inductions when using the CRT technique in portable devices, e.g. in smart cards.

## 6 Mechanisms based on discrete logarithms with respect to prime numbers

### 6.1 Security requirements for the environment

These mechanisms enable a verifier to check that a claimant knows the discrete logarithm of a claimed public key with respect to a prime number.

NOTE These mechanisms implement schemes due to Schnorr<sup>[21]</sup> and denoted SC.

Within a given domain, the following requirements shall be satisfied.

- Domain parameters shall be selected, which will govern the operation of the mechanism. The selected parameters shall be made known in a reliable manner to all entities within the domain.
- The number used as the base of discrete logarithms shall be so that, for any arbitrary number  $j$ , non-zero and less than the modulus, finding a number  $k$  (if one exists), so that the  $k$ -th modular power of the base is  $j$ , shall be computationally infeasible, where feasibility is defined by the context of use of the mechanism.
- Every claimant shall be equipped with a private key.
- Every verifier shall obtain a trusted copy of the public key specific to the claimant.

NOTE The exact means by which the verifier obtains a trusted copy of the public key specific to the claimant is beyond the scope of this part of ISO/IEC 9798. This may, for example, be achieved by the use of public-key certificates or by some other environment-dependent means.

- Every claimant and every verifier shall have the means to produce random numbers.
- If the mechanism makes use of a hash-function, then all entities within the domain shall agree on a hash-function, e.g. one of the functions specified in ISO/IEC 10118-3<sup>[25]</sup>.

### 6.2 Key production

Three numbers, denoted  $p$ ,  $q$  and  $g$ , shall be selected in accordance with the context of use of the mechanism.

— The modulus  $p$  shall be a prime number. The bit size of the number  $p$  is denoted  $|p|$ .

- The number  $q$  shall be a prime factor of  $p-1$ . Unless otherwise specified, the bit size of the number  $q$  is 160, i.e.  $|q| = 160$ .
- The base of the discrete logarithms, denoted  $g$ , shall be of order  $q$  modulo  $p$ , i.e. a number greater than 1 so that  $g^q \bmod p = 1$ . The base  $g$  is conveniently represented as a string of  $|p|$  bits.

NOTE 1 The prime number  $p$  can be selected so that a copy of the binary representation of  $q$  is embedded within the binary representation of  $p$ . Such an approach for choosing  $p$  and  $q$  may be useful in situations where storage space and/or communications bandwidth is at a premium. See an example in D.5.1.

NOTE 2 If there is an odd factor less than  $q$  dividing  $p-1$ , then the private key may be compromised by an attack of the type described by Lim and Lee [15]. To prevent such an attack,  $p$  and  $q$  should be selected so that  $(p-1)/(2 \times q)$  has no prime factor less than  $q$ . Ideally,  $(p-1)/(2 \times q)$  should be prime.

Each claimant  $A$  shall be provided with a fresh number uniformly selected at random, non-zero and less than  $q$ , representing a private key denoted  $Q$ . It is represented by a string of  $|q|$  bits.

Denoted  $G(A)$ , the public key for claimant  $A$  is set equal to the  $Q$ -th modular power of the base  $g$ . It is represented by a string of  $|p|$  bits.

$$G(A) = g^Q \bmod p$$

A number, denoted  $\delta$ , fixes the number of bits for representing challenges. A value of  $\delta$  from 8 to 40 is appropriate for most applications. Unless otherwise specified, the value of  $\delta$  is set equal to 40.

NOTE The total number of possible challenges should be limited to  $2^{40}$ . If this recommendation is not followed, then special care should be taken to prevent the verifier using the claimant as a signing oracle.

### 6.3 Unilateral authentication exchange

The bracketed numbers in Figure 3 correspond to the steps of the mechanism, including the exchanges of information, described in detail below. The claimant is denoted  $A$ . The verifier is denoted  $B$ .

Figure 3 — Mechanism using a discrete logarithm with respect to a prime number

In addition to prime numbers  $p$  and  $q$ , a number  $\delta$  and a base  $g$ , the claimant shall store a private key  $Q$ .

In the case of a coupon strategy, the claimant shall store a private key  $Q$ , a number  $\delta$  and a set of coupons. To be used only once, each coupon consists of a  $|q|$ -bit number (that needs not be stored if it can be reproduced by a pseudo-random function) and an  $\alpha$ -bit witness (or preferably, its hash-code).

In addition to prime numbers  $p$  and  $q$ , a number  $\delta$  and a base  $g$ , the verifier shall be provided with a trusted copy of a claimed public key  $G(A)$ .

For each application of the mechanism, the following procedure shall be performed. The verifier  $B$  shall only accept the claimant  $A$  as valid if the procedure completes successfully.

- 1) For each authentication, a fresh number shall be uniformly selected at random, non-zero and less than  $q$ . Denoted  $r$ , it shall be kept secret. The fresh random number  $r$  shall be converted into a witness, denoted  $W$ . The number  $W$  is represented by a string of  $\alpha$  bits, also denoted  $W$ .

Witness formula: 
$$W = g^r \bmod p$$

- 2)  $A$  sends  $\text{TokenAB}_1$  to  $B$ .  $\text{TokenAB}_1$  is either witness  $W$  or a hash-code of  $W$  and  $\text{Text}$ , one of the following four hash variants.

The four hash variants are  $h(W \parallel \text{Text})$ ,  $h(W \parallel h(\text{Text}))$ ,  $h(h(W) \parallel \text{Text})$ , and  $h(h(W) \parallel h(\text{Text}))$ , where  $h$  is a hash-function and  $\text{Text}$  is an optional text field (it may be empty). If the text field is non-empty, then  $B$  shall have the means to recover the value of  $\text{Text}$ ; this may require  $A$  to send all or part of the text field at this point. The text field is available for use in applications outside the scope of this part of ISO/IEC 9798. Annex A of ISO/IEC 9798-1<sup>[24]</sup> gives information on the use of text fields. The hash variant is a domain parameter.

- 3) On receipt of  $\text{TokenAB}_1$ , a fresh string of  $\delta$  bits shall be uniformly selected at random.
- 4)  $B$  sends the fresh string as a challenge to  $A$ . The fresh string represents a number denoted  $d$ .
- 5) On receipt of the challenge, the following computational steps are performed.
  - a) If the challenge is not a string of  $\delta$  bits, then the procedure fails.
  - b) A response  $D$  shall be computed from the random number  $r$  and the private key  $Q$ .  
Response formula: 
$$D = r - d \times Q \pmod{q}$$
- 6)  $A$  sends  $\text{TokenAB}_2$  to  $B$ .  $\text{TokenAB}_2$  is the response  $D$  computed from step 5)b).
- 7) On receipt of  $\text{TokenAB}_2$ , the following computational steps are performed.
  - a) If the response  $D$  is **zero** or equal to or more than  $q$ , then the procedure fails.
  - b) Denoted  $W^*$ , a witness shall be computed using the public key  $G(A)$ .  
Verification formula: 
$$W^* = G(A)^d \times g^D \pmod{p}$$
  - c) If either witness  $W^*$  or a hash-code of  $W^*$  and  $\text{Text}$ , one of the four hash variants, is identical to  $\text{TokenAB}_1$ , received in step (2), then the procedure is successful. Otherwise the procedure fails.

NOTE 1 Other information may be sent with any exchange of the procedure.  $B$  may use such information to help compute the value of the optional text field. For example,  $A$  may send information such as certificates with  $\text{TokenAB}_1$ .

NOTE 2 The use of a hash-code instead of witness  $W$  in  $\text{TokenAB}_1$  can achieve efficiency gains by reducing the number of bits in  $\text{TokenAB}_1$ .

## 7 Mechanisms based on discrete logarithms with respect to composite numbers

### 7.1 Security requirements for the environment

These mechanisms enable a verifier to check that a claimant knows the discrete logarithm of a public key with respect to a composite number. The public key and  $l$  or the composite number are claimed.

NOTE These mechanisms implement schemes due to Girault, Poupard and Stern<sup>[5][19]</sup> for GPS1, and to Girault and Paillès<sup>[8]</sup> for GPS2.

Within a given domain, the following requirements shall be satisfied.

- 1) Domain parameters shall be selected, which will govern the operation of the mechanism. These domain parameters include one of the two modes of use specified hereafter. The selected parameters shall be made known in a reliable manner to all entities within the domain.
- 2) Every claimant shall be equipped with a modulus that is either a domain parameter or a claimant parameter. Each number used as modulus shall be so that knowledge of its value shall not feasibly enable any entity to deduce its prime factors, where feasibility is defined by the context of use of the mechanism.
- 3) Each number used as the base of discrete logarithms shall be so that, for any arbitrary number  $j$ , non-zero and less than the modulus, finding a number  $k$  (if one exists), so that the  $k$ -th modular power of the base is  $j$ , shall be computationally infeasible, where feasibility is defined by the context of use of the mechanism.
- 4) Every claimant shall be equipped with a private key.
- 5) Every verifier shall obtain a trusted copy of the public key(s) specific to the claimant.

NOTE The exact means by which the verifier obtains a trusted copy of the public key(s) specific to the claimant is beyond the scope of this part of ISO/IEC 9798. This may, for example, be achieved by the use of public-key certificates or by some other environment-dependent means.

- 6) Every claimant and every verifier shall have the means to produce fresh strings of random bits.
- 7) If the mechanism makes use of a hash-function, then all entities within the domain shall agree on a hash-function, e.g. one of the functions specified in ISO/IEC 10118-3<sup>[25]</sup>.

**7.2 Key production**

**7.2.1 General**

A number, denoted  $\alpha$ , fixes the modulus size in bits, i.e.  $2^{\alpha-1} < \text{modulus} < 2^\alpha$ , in accordance with the context of use of the mechanism (for further details, see C.1.1). It is a domain parameter.

A number, denoted  $\delta$ , fixes the number of bits for representing challenges. A value from 8 to 40 is appropriate for most applications. Unless otherwise specified, the value of  $\delta$  is set equal to 40. It is a domain parameter.

NOTE The total number of possible challenges should be limited to  $2^{40}$ . If this recommendation is not followed, then special care should be taken to prevent the verifier using the claimant as a signing oracle.

Within the domain, a mode of use shall be selected from the two modes specified hereafter.

**7.2.2 First mode of use (GPS1)**

A number, denoted  $\sigma$ , fixes the number of bits for representing private keys. Unless otherwise specified, the value of  $\sigma$  is set equal to 160. It is a domain parameter.

For claimant  $A$ , a fresh string of  $\sigma$  bits shall be uniformly selected at random. The string represents the private key, denoted  $Q$ .

Denoted  $g$ , the base of the discrete logarithms is a domain parameter. The value  $g = 2$  has some practical advantages.

The modulus is either a domain parameter denoted  $n$ , or a claimant parameter denoted  $n(A)$ . In both cases, the factorization of the modulus, i.e. the large prime factors (for further details, see C.1.2), may be unknown.

Denoted  $G(A)$ , the public key for claimant  $A$  is set equal to the  $Q$ -th modular power of the base  $g$ . It is represented by a string of  $\alpha$  bits.

$$G(A) = g^Q \pmod{\text{either } n \text{ or } n(A)}$$

**7.2.3 Second mode of use (GPS2)**

Denoted  $v$ , the verification exponent is a domain parameter. It shall be prime and greater than  $2^\delta$ . As the value of  $\delta$  is set equal to 40, unless otherwise specified, the value of  $v$  is set equal to  $2^{40} + 15$  (a prime number).

Claimant  $A$  shall keep secret two or more distinct large prime factors, denoted  $p_1, p_2 \dots$  in ascending order. If  $\alpha$  is a multiple of the number of prime factors, denoted  $f$ , then the bit size of each prime factor shall be  $\alpha / f$  (for further details, see C.1.2). For each prime factor  $p_j$ ,  $p_j - 1$  shall be co-prime to  $v$ .

The modulus is set equal to the product of the prime factors, i.e.  $p_1 \times \dots \times p_f$ . It is a claimant parameter denoted  $n(A)$ .

NOTE 1 The verification exponent  $v$  and the modulus  $n(A)$  together form a public RSA key.

Denoted  $Q$ , the private key for claimant  $A$  is the least positive integer so that  $v \times Q - 1$  is a multiple of  $\text{lcm}(p_1 - 1, \dots, p_f - 1)$ . The number  $Q$  is represented by a string of  $\alpha$  bits.

NOTE 2 The private key  $Q$  and the modulus  $n(A)$  together form a private RSA key.

Denoted  $G$ , the public key is a domain parameter. The value  $G = 2$  has some practical advantages.

NOTE 3 The number playing the role of the base is the  $v$ -th modular power of  $G$ , i.e.  $g(A) = G^v \text{ mod } n(A)$ . It is used neither by the claimant, nor by the verifier.

### 7.3 Unilateral authentication exchange

The bracketed numbers in Figure 4 correspond to the steps of the mechanism, including the exchanges of information, described in detail below. The claimant is denoted  $A$ . The verifier is denoted  $B$ .

Figure 4 — Mechanism using a discrete logarithm with respect to a composite number

- In the first mode, the claimant shall store a number  $\delta$ , a base  $g$ , a private key  $Q$  (as a string of  $\sigma$  bits) and a modulus  $n$  or  $n(A)$ . Unless otherwise specified,  $\delta = 40$ ,  $g = 2$ ,  $\sigma = 160$ .
- In the second mode, the claimant shall store a number  $\delta$ , a public key  $G$ , a verification exponent  $v$ , a private key  $Q$  (as a string of  $\alpha$  bits) and a modulus  $n(A)$ . Unless otherwise specified,  $\delta = 40$ ,  $G = 2$ ,  $v = 2^{40} + 15$ .

In the case of a coupon strategy, in addition to a number  $\delta$  and a private key  $Q$ , the claimant shall only store a set of coupons. To be used only once, each coupon consists of a  $\rho$ -bit string (that needs not be stored if it can be reproduced by a pseudo-random function) and an  $\alpha$ -bit witness (or preferably, its hash-code).

- In the first mode, in addition to a number  $\delta$ , a base  $g$  and a number  $\sigma$ , the verifier shall be provided with a trusted copy of a public key  $G(A)$  and a trusted copy of a modulus  $n$  or  $n(A)$ .
- In the second mode, in addition to a number  $\delta$ , a public key  $G$  and a verification exponent  $v$ , the verifier shall be provided with a trusted copy of a modulus  $n(A)$ .

For each application of the mechanism, the following procedure shall be performed. The verifier  $B$  shall only accept the claimant  $A$  as valid if the procedure completes successfully.

- 1) For each authentication, a fresh string of  $\rho$  bits shall be uniformly selected at random. It shall be kept secret.

In the first mode, 
$$\rho = \sigma + \delta + 80.$$

In the second mode, 
$$\rho = \alpha + \delta + 80.$$

NOTE 1 If the fresh string of  $\rho$  bits is selected at random, then the probability that the leftmost 80 bits are all equal is negligible.

Denoted  $r$ , the number represented by the fresh string shall be converted into a witness, denoted  $W$ . The number  $W$  is represented by a string of  $\alpha$  bits, also denoted  $W$ .

Witness formula in the first mode: 
$$W = g^r \text{ (mod either } n \text{ or } n(A))$$

Witness formula in the second mode: 
$$W = G^{r \times v} \text{ mod } n(A)$$

NOTE 2 If the prime factors are available, then the witness computation (performed in advance in the case of a coupon strategy) may make use of the CRT technique (see C.2.3).

- 2) A sends  $\text{TokenAB}_1$  to B.  $\text{TokenAB}_1$  is either witness  $W$  or a hash-code of  $W$  and  $\text{Text}$ , one of the following four hash variants.

The four hash variants are  $h(W \parallel \text{Text})$ ,  $h(W \parallel h(\text{Text}))$ ,  $h(h(W) \parallel \text{Text})$ , and  $h(h(W) \parallel h(\text{Text}))$ , where  $h$  is a hash-function and  $\text{Text}$  is an optional text field (it may be empty). If the text field is non-empty, then B shall have the means to recover the value of  $\text{Text}$ ; this may require A to send all or part of the text field at this point. The text field is available for use in applications outside the scope of this part of ISO/IEC 9798. Annex A of ISO/IEC 9798-1<sup>[24]</sup> gives information on the use of text fields. The hash variant is a domain parameter.

- 3) On receipt of  $\text{TokenAB}_1$ , a fresh string of  $\delta$  bits shall be uniformly selected at random.

- 4) B sends the fresh string as a challenge to A. The fresh string represents a number denoted  $d$ .

- 5) On receipt of the challenge, the following computational steps are performed.

- a) If the challenge is not a string of  $\delta$  bits, then the procedure fails.
- b) A response  $D$  shall be computed from the random number  $r$  and the private key  $Q$ .

Response formula: 
$$D = r - d \times Q$$

- 6) A sends  $\text{TokenAB}_2$  to B.  $\text{TokenAB}_2$  is the response  $D$  computed from step 5)b).

- 7) On receipt of  $\text{TokenAB}_2$ , the following computational steps are performed.

- a) If the response  $D$  is not a string of  $\rho$  bits and/or if the leftmost 80 bits of  $D$  are all equal, then the procedure fails.
- b) Denoted  $W^*$ , a witness shall be computed.

Verification formula in the first mode: 
$$W^* = G(A)^d \times g^D \pmod{\text{either } n \text{ or } n(A)}$$

Verification formula in the second mode: 
$$W^* = G^{d+r \times D} \pmod{n(A)}$$

- c) If either witness  $W^*$  or a hash-code of  $W^*$  and  $\text{Text}$ , one of the four hash variants, is identical to  $\text{TokenAB}_1$  received in step (2), then the procedure is successful. Otherwise the procedure fails.

NOTE 1 Other information may be sent with any exchange of the procedure. B may use such information to help compute the value of the optional text field. For example, A may send information such as certificates with  $\text{TokenAB}_1$ .

NOTE 2 The use of a hash-code instead of witness  $W$  in  $\text{TokenAB}_1$  can achieve efficiency gains by reducing the number of bits in  $\text{TokenAB}_1$ .

## 8 Mechanisms based on asymmetric encryption systems

### 8.1 Security requirements for the environment

These mechanisms enable a verifier to check that a claimant knows the decryption key corresponding to a claimed encryption key.

NOTE These mechanisms derive from schemes due to Brandt, Damgård, Landrock and Pedersen<sup>[2][16]</sup>. The second mechanism also derives from the key transport mechanism 6 from ISO/IEC 11770-3<sup>[26]</sup>, and Mitchell and Yeun<sup>[17]</sup>.

Within a given domain, the following requirements shall be satisfied.

- 1) All entities within the domain shall agree on the use of two cryptographic functions: a hash-function, e.g. one of the functions specified in ISO/IEC 10118-3<sup>[25]</sup>, and an asymmetric encryption system, e.g. one of the systems specified in ISO/IEC 18033-2<sup>[31]</sup>.
- 2) Every claimant shall be equipped with an asymmetric key pair for use with the asymmetric encryption system.

- 3) Every verifier shall obtain a trusted copy of the public key specific to the claimant.

NOTE The exact means by which the verifier obtains a trusted copy of the public key specific to the claimant is beyond the scope of this part of ISO/IEC 9798. This may, for example, be achieved by the use of public-key certificates or by some other environment-dependent means.

- 4) Every verifier shall have the means to produce fresh strings of random bits.

## 8.2 Unilateral authentication exchange

The bracketed numbers in Figure 5 correspond to the steps of the mechanism, including the exchanges of information, described in detail below. The claimant is denoted *A*. The verifier is denoted *B*.

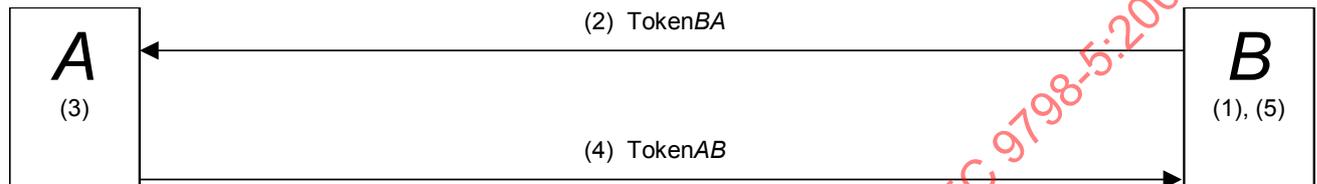

Figure 5 — Mechanism using an asymmetric key pair for encryption

The claimant shall store the private portion of an asymmetric key pair, defining a private operation denoted  $S_A$ .

The verifier shall be provided with a trusted copy of the public portion of an asymmetric key pair, defining a public operation denoted  $P_A$ .

If a coupon strategy is being used, the verifier shall store a set of coupons. To be used only once, each coupon is dedicated to a given claimant; it consists of a  $\rho$ -bit string (that needs not be stored if it can be reproduced by a pseudo-random function) and an  $\alpha$ -bit challenge.

The bit length of the fresh strings of random bits, a number denoted  $\rho$ , shall be selected. The value of  $\rho$  shall be at least  $2 \times |h|$ , but less than  $|n(A)| - |h|$ , so that the concatenation of a fresh string with a hash-code lies within the domain of definition of  $P_A$ .

For each application of the mechanism, the following procedure shall be performed. The verifier *B* shall only accept the claimant *A* as valid if the procedure completes successfully.

- 1) The following computational steps are performed.
  - a) For each authentication, a fresh string of  $\rho$  bits shall be uniformly selected at random. Denoted  $r$ , it shall be kept secret.

The value of  $\rho$  shall be at least  $2 \times |h|$ , but less than  $|n(A)| - |h|$ , so that the concatenation of a fresh string with a hash-code lies within the domain of definition of  $P_A$ .

- b) A hash-code  $H$  shall be computed from the fresh string  $r$ .

$$H = h(r)$$

- c) A number  $d$  shall be computed using  $P_A$ .

$$d = P_A(r || H)$$

- 2) *B* sends Token $BA$  to *A*. Token $BA$  is the number  $d$  computed from step 1)c).

- 3) On receipt of Token $BA$ , the following computational steps are performed.

- a) Two strings denoted  $r^*$  and  $H^*$  shall be recovered using  $S_A$ .

$$r^* || H^* = S_A(d)$$

- b) If the string  $H^*$  and the hash-code  $h(r^*)$  are different, then the procedure fails.

- 4) A sends TokenAB to B. TokenAB is the string  $r^*$  recovered from step 3)a).
- 5) On receipt of TokenAB, the string  $r^*$  is compared with the string  $r$ . If they are identical, then the procedure is successful; otherwise the procedure fails.

NOTE 1 If the encryption system in use provides the property of non-malleability (see ISO/IEC 18033-2<sup>[31]</sup>), then the hash-code may be omitted from TokenBA. In such a case, step 3.b is replaced by a check that the decryption process completes correctly. However special care should then be taken to prevent the verifier using the claimant as a decryption oracle.

NOTE 2 Other information may be sent with either of the exchanges of the mechanism.

### 8.3 Mutual authentication exchange

The bracketed numbers in Figure 6 correspond to the steps of the mechanism, including the exchanges of information, described in detail below. Each entity, A as B, is a claimant and a verifier.

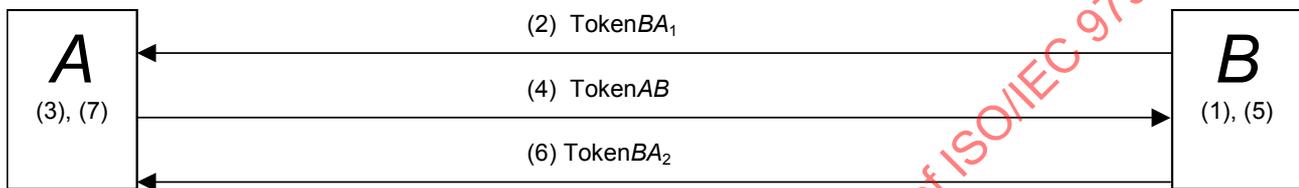

Figure 6— Mechanism using two asymmetric key pairs for encryption

Each entity shall store the private portion of their asymmetric key pair, defining a private operation denoted either  $S_A$ , or  $S_B$  and be provided with a trusted copy of the public portion of the asymmetric key pair of the other entity, defining a public operation denoted either  $P_B$ , or  $P_A$ . It shall also be provided with its own identification data, denoted either  $Id(A)$  or  $Id(B)$ , and the identification data of the other entity, denoted either  $Id(B)$  or  $Id(A)$ .

The bit length of the fresh strings of random bits, a number denoted  $\rho$ , shall be selected. The value of  $\rho$  shall be at least  $2 \times |h|$ , but less than  $\min(|n(A)| - |h| - |Id(B)|, (|n(B)| - |h| - |Id(A)|)/2)$ , so that

- the concatenation of  $Id(B)$  and a fresh string with a hash-code lies within the domain of definition of  $P_A$ .
- the concatenation of  $Id(A)$  and two fresh strings with a hash-code lies within the domain of definition of  $P_B$ .

For each application of the mechanism, the following procedure shall be performed. The two entities A and B shall only accept each other as valid if the procedure completes successfully.

- 1) The following computational steps are performed.
  - a) For each authentication, a fresh string of  $\rho$  bits shall be uniformly selected at random. Denoted  $r_B$ , it shall be kept secret.
  - b) A hash-code  $H_B$  shall be computed from the identification data  $Id(B)$  and the fresh string  $r_B$ .

$$H_B = h(Id(B) || r_B)$$

- c) A number  $d_B$  shall be computed using  $P_A$ .

$$d_B = P_A(Id(B) || r_B || H_B)$$

- 2) B sends TokenBA<sub>1</sub> to A. TokenBA<sub>1</sub> is the number  $d_B$  computed from step 1)c).

- 3) On receipt of TokenBA<sub>1</sub>, the following computational steps are performed.

- a) Three strings denoted  $Id_B^*$ ,  $r_B^*$  and  $H_B^*$  shall be recovered using  $S_A$ .

$$Id_B^* || r_B^* || H_B^* = S_A(d_B)$$

- b) If the string  $H_B^*$  and the hash-code  $h(Id_B^* || r_B^*)$  are different, then the procedure fails.
  - c) If the string  $Id_B^*$  and the identification data  $Id(B)$  are different, then the procedure fails.

- d) The following computational steps are performed.
- i. For each authentication, a fresh string of  $\rho$  bits shall be uniformly selected at random. Denoted  $r_A$ , it shall be kept secret.
  - ii. A hash-code  $H_A$  shall be computed from the identification data  $Id(A)$ , the string  $r_B^*$  and the fresh string  $r_A$ .

$$H_A = h(Id(A) \parallel r_B^* \parallel r_A)$$

- iii. A number  $d_A$  shall be computed using  $P_B$ .

$$d_A = P_B(Id(A) \parallel r_B^* \parallel r_A \parallel H_A)$$

- 4)  $A$  sends  $TokenAB$  to  $B$ .  $TokenAB$  is the number  $d_A$ .
- 5) On receipt of  $TokenAB$ , the following computational steps are performed.
  - a) Four strings denoted  $Id_A^*$ ,  $r_B^{**}$ ,  $r_A^*$  and  $H_A^*$  shall be recovered using  $S_B$ .
 
$$Id_A^* \parallel r_B^{**} \parallel r_A^* \parallel H_A^* = S_B(d_A)$$
  - b) If the string  $H_A^*$  and the hash-code  $h(Id_A^* \parallel r_B^{**} \parallel r_A^*)$  are different, then the procedure fails.
  - c) If the string  $Id_A^*$  and the identification data  $Id(A)$  are different, then the procedure fails.
  - d) If the string  $r_B^{**}$  and the string  $r_B$  produced at step (1) are different, then the procedure fails.
- 6)  $B$  sends  $TokenBA_2$  to  $A$ .  $TokenBA_2$  is the string  $r_A^*$ .
- 7) On receipt of  $TokenBA_2$ , the string  $r_A^*$  is compared with the string  $r_A$  produced at step (3). If they are identical, then the procedure is successful; otherwise the procedure fails.

NOTE 1 If the encryption system in use provides the property of non-malleability (see ISO/IEC 18033-2<sup>[31]</sup>), then the hash-codes may be omitted from  $TokenBA_1$  and  $TokenAB$ . In such a case, steps 3.b and 5.b are replaced by checks that the decryption process completes correctly. However special care should then be taken to prevent the verifier using the claimant as a decryption oracle.

NOTE 2 Other information may be sent with any of the exchanges of the mechanism.

## 9 Mechanism based on discrete logarithms with respect to elliptic curves

### 9.1 Security requirements for the environment

This mechanism enables a verifier to check that a claimant knows the elliptic curve discrete logarithm of a claimed public point with respect to a base point. A general framework for cryptographic techniques based on elliptic curves is given in ISO/IEC 15946-1 [28].

NOTE 1 This mechanism implements the elliptic curve variant<sup>[6]</sup> of the GPS<sup>[9]</sup> scheme due to Girault, Poupard and Stern. It allows use of the so-called LHW (Low Hamming Weight) variant<sup>[7]</sup>, particularly suitable for environments where the resources of the claimant are very low.

Within a given domain, the following requirements shall be satisfied.

- 1) Domain parameters that govern the operation of the mechanism shall be selected. The selected parameters shall be made available in a reliable manner to all entities within the domain.
- 2) Every claimant shall be equipped with an elliptic curve  $E$  and a set of parameters, namely the field size  $q$ , a base point  $P$  over  $E$ , and  $n$  the order of point  $P$ . The curve and the set of parameters are either domain parameters or claimant parameters.
- 3) Each point  $P$  used as the base for elliptic curve discrete logarithms shall be such that, for any arbitrary point  $J$  of the curve, finding a number  $k$  in  $[0, n - 1]$  (if one exists), so that  $J = [k]P$  is computationally infeasible, where feasibility is defined by the context of use of the mechanism.
- 4) Every claimant shall be equipped with a private key.

5) Every verifier shall obtain an authentic copy of the public key corresponding to the claimant's private key.

NOTE 2 The exact means by which the verifier obtains a trusted copy of the public point specific to the claimant is beyond the scope of this part of ISO/IEC 9798. This may, for example, be achieved by the use of public-key certificates or by some other environment-dependent means.

6) Every claimant and every verifier shall have the means to produce fresh strings of random bits.

7) If the mechanism makes use of a hash-function, then all entities within the domain shall agree on a hash-function, e.g. one of the functions specified in ISO/IEC 10118-3<sup>[25]</sup>.

### 9.2 Key production

For claimant *A*, a fresh string shall be uniformly selected at random from the set  $[2, n - 2]$ . The string represents the private key, denoted *Q*.

The number  $\sigma = |n|$  gives the number of bits to be used to represent private keys.

Denoted  $G(A)$ , the public point for claimant *A* is set equal to the multiplication of number *Q* by the base point *P*.

$$G(A) = (x_G, y_G) = [Q]P$$

The challenges are selected from a set of integers *S* of cardinality  $\Delta$ , where  $2^{\delta-1} < \Delta \leq 2^\delta$ . The length in bits of the greatest possible challenge is denoted by  $\beta$ . A value of  $\delta$  from 8 to 40 is appropriate for most applications. Unless otherwise specified, the value of  $\delta$  is set equal to 40. It is a domain parameter.

NOTE 1 The total number of possible challenges should be limited to  $2^{40}$ . If this recommendation is not followed, then special care should be taken to prevent the verifier using the claimant as a signing oracle.

NOTE 2 When the set of challenges is the interval  $[0, \Delta - 1]$ , then:  $\beta = \delta$ .

NOTE 3 A challenge is said to be LHW (Low Hamming Weight) if there are at least  $\sigma - 1$  zero bits between any two consecutive one bits in its binary representation.

### 9.3 Unilateral authentication exchange

The bracketed numbers in Figure 7 correspond to the steps of the mechanism, including the exchanges of information, described in detail below. The claimant is denoted by *A*. The verifier is denoted by *B*.

Figure 7 — Mechanism using a discrete logarithm with respect to elliptic curves

The claimant shall store a number  $\delta$ , a base *P*, and a private key *Q* (as a string of  $\sigma$  bits). Unless otherwise specified,  $\delta = 40$ .

In the case of a coupon strategy, in addition to a number  $\delta$  and a private key *Q*, the claimant shall only store a set of coupons. To be used only once, each coupon consists of a  $\rho$ -bit string (that need not be stored if it can be reproduced by a pseudo-random function) and a witness.

In addition to a number  $\delta$  and a number  $\sigma$ , the verifier shall be provided with a trusted copy of a public point  $G(A)$  and a trusted copy of the curve *E*, the base point *P* and the parameters *q* and *n*.

For each application of the mechanism, the following procedure shall be performed. The verifier *B* shall only accept the claimant *A* as valid if the procedure completes successfully.

- 1) For each authentication, a fresh string of  $\rho$  bits shall be uniformly selected at random. It shall be kept secret.

$$\rho = \sigma + \beta + 80$$

NOTE 1 If the fresh string of  $\rho$  bits is selected at random, then the probability that the leftmost 80 bits are all equal is negligible.

Denoted  $r$ , the number represented by the fresh string shall be converted into a witness, denoted  $W$ .

Witness formula:  $W = P2OS([r]P)$

NOTE 2  $P2OS$  is the function used to convert a point to an octet string.

- 2) *A* sends  $TokenAB_1$  to *B*.  $TokenAB_1$  can be either witness  $W$  or a hash-code of  $W$  and  $Text$ , one of the following four hash variants, to *B*.

The four hash variants are  $h(W \parallel Text)$ ,  $h(W \parallel h(Text))$ ,  $h(h(W) \parallel Text)$ , and  $h(h(W) \parallel h(Text))$ , where  $h$  is a hash-function and  $Text$  is an optional text field (it may be empty). If the text field is non-empty, then *B* shall have the means to recover the value of  $Text$ ; this may require that *A* sends all or part of the text field with the token. How the text field is made available for use in applications is outside the scope of this part of ISO/IEC 9798. Annex A of ISO/IEC 9798-1<sup>[24]</sup> gives information on the use of text fields. The hash variant is a domain parameter.

- 3) On receipt of  $TokenAB_1$ , a fresh string shall be uniformly selected at random from the set  $S$ .
- 4) *B* sends the fresh string as a challenge to *A*. The fresh string represents a number denoted  $d$ .

NOTE 3 If an LHW challenge is used, it can be transmitted in a compressed form to *A* who must have the means to retrieve the original challenge before step 5a

- 5) On receipt of the challenge, the following computational steps are performed.
  - a) If the challenge is not an element of  $S$ , then the procedure fails.
  - b) A response  $D$  shall be computed from the random number  $r$  and the private key  $Q$ .

Response formula:  $D = r - d \times Q$

NOTE 4 If the challenge received is an LHW challenge, the computation of  $D$  is reduced to a serial addition of  $r$  with a concatenation of copies of  $Q$ , separated by zero bits.

- 6) *A* sends  $TokenAB_2$  to *B*.  $TokenAB_2$  is the response  $D$  computed from step 5)b).
- 7) On receipt of  $TokenAB_2$ , the following computational steps are performed.
  - a) If the response  $D$  is not a string of  $\rho$  bits and/or if the leftmost 80 bits of  $D$  are all equal, then the procedure fails.
  - b) Denoted  $W^*$ , a witness shall be computed.

Verification formula:  $W^* = P2OS([d]G(A) + [D]P)$

- c) If either witness  $W^*$  or a hash-code of  $W^*$  and  $Text$  (one of four hash variants) is identical to  $TokenAB_1$  received in step (2), then the procedure is successful. Otherwise the procedure fails.

NOTE 5 Other information may be sent with any exchange of the procedure. *B* may use such information to help compute the value of the optional  $Text$  field. For example, *A* may send information such as certificates with  $TokenAB_1$ .

#### A.2 Use of subsequent object identifiers

If a mechanism specified in this part of ISO/IEC 9798 uses a hash-function, then just after an object identifier identifying the mechanism, another object identifier may follow for identifying a hash-function (e.g. one of the dedicated hash-functions specified in ISO/IEC 10118-3<sup>[25]</sup>).

For the last two mechanisms, another object identifier may follow for referring to an encryption system (e.g. one of the mechanisms specified in ISO/IEC 18033-2<sup>[31]</sup>). In the absence of such a subsequent object identifier, an RSA permutation is used.

### A.3 Coding examples in accordance with the basic encoding rules of ASN.1

In accordance with ISO/IEC 8825-1<sup>[23]</sup>, an object identifier consists of one or more series of octets. Each series codes a number.

- Bit 8 (the most significant bit) is set equal to zero in the last octet of a series and to one in the previous octets, if there is more than one octet.
- The concatenation of bits 7 to 1 of the octets of a series codes a number. Each number shall be encoded on the fewest possible octets, that is, the octet '80' is invalid in the first position of a series.
- The first number is the number of the standard; the second number, if present, is the part in a multi-part standard.

An object identifier may refer to any mechanism defined in this part of ISO/IEC 9798.

- For identifying an ISO standard, the first octet is set equal to '28', i.e. 40 in decimal (see ISO/IEC 8825-1).
- The next two octets are set equal to 'CC46'. 9798 is equal to '2646' in hexadecimal, i.e. 0010 0110 0100 0110, i.e. two blocks of seven bits: 1001100 1000110. After insertion of the appropriate value of bit 8 in each octet, the coding of the series is therefore 11001100 01000110, i.e. 'CC46'.
- The next octet is set equal to '05' for identifying part 5.
- The next octet identifies an authentication mechanism.
  - '01' identifies the unilateral authentication mechanism using FS.
  - '02' identifies the unilateral authentication mechanism using GQ1.
  - '03' identifies the unilateral authentication mechanism using the factorization of a modulus, i.e. GQ2.
  - '04' identifies the unilateral authentication mechanism using a discrete logarithm with respect to a prime number, i.e. SC.
  - '05' identifies the unilateral authentication mechanism using a discrete logarithm with respect to a composite number in the first mode of use, i.e. GPS1.
  - '06' identifies the unilateral authentication mechanism using a discrete logarithm with respect to a composite number in the second mode of use, i.e. GPS2.
  - '07' identifies the unilateral authentication mechanism using an asymmetric encryption system.
  - '08' identifies the mutual authentication mechanism using an asymmetric encryption system.

For example, the data element '28 CC 46 05 03' reads {iso standard 9798 5 3}, i.e. the third mechanism in ISO/IEC 9798-5, i.e. GQ2. The data element may be conveyed in the following BER-TLV data object (see the basic encoding rules of ASN.1, ISO/IEC 8825-1, universal class tag '06') where the dashes and the curly brackets inserted for clarity are not significant.

Data object = '06'-'05'-'28 CC 46 05 03'

## Annex B (informative)

### Principles of zero-knowledge techniques

#### B.1 Introduction

In the context of the use of asymmetric cryptographic techniques, a potential weakness of an authentication exchange is that the verifier may abuse the mechanism to compromise the private key. When asymmetric cryptography is being used, the claimant uses the private key of his asymmetric pair to compute a response to a verifier's challenge. The verifier may then, by choosing the challenge wisely, gain information about the private key of the claimant that could not have been obtained just from knowledge of the public key of the claimant.

This type of abuse of an exchange of cryptographic messages is known as using the claimant as an oracle, in that the claimant provides information about his private key at the behest of the verifier. The idea behind a zero-knowledge authentication mechanism is simply to remove this particular potential threat by careful design of the messages in such a way that the verifier cannot use the claimant as an oracle.

#### B.2 Need for zero-knowledge mechanisms

In applications involving modern computer networks, the need for security services such as authentication, non-repudiation, etc., is widely recognized and steadily growing. In order to be able to use such services, it is necessary for a user to have access to private information, specific to that user. Examples are passwords, signature keys, private keys of asymmetric pairs, etc.

It is of course mandatory for the security of the system that the private information stays private, i.e. does not leak to other potentially hostile parties. On the other hand, the private information shall be used as input to the software or hardware modules that compute and send messages on behalf of the user. If the information is not properly used, the secrecy of the private information may be damaged, or even destroyed completely. An obvious example is when users identify themselves to a host by sending a password in cleartext. This reveals totally the private information with the immediate result that anyone eavesdropping on the line can impersonate all users whose passwords have been intercepted.

This is an example where too much information is being communicated. To illustrate this, note that from the point of view of the host, there are only two possibilities: either the user possesses the correct password or he does not. In information theoretic terms, this means that only one bit of information really needs to be communicated. By sending the entire password, we therefore communicate much more than is needed, and this is the theoretical background for the practical problem of eavesdropping.

It is natural to ask: "— Can one design protocols for use of private information which communicate exactly the information they are meant to communicate, and nothing more?" Informally, this is precisely the property that a zero-knowledge mechanism has. Consider for example a situation where user *A* is assigned an asymmetric pair of keys or numbers for an asymmetric cryptographic system ( $P_A$ ,  $S_A$ ), so that  $P_A$  is public while  $S_A$  is private to *A*. Then using a zero-knowledge mechanism, *A* can convince *B* that *A* possesses the private key corresponding to  $P_A$  without revealing anything other than this fact. Since *A* is characterized as the only user with access to  $S_A$ , this protocol can be used for authentication. In this case, the zero-knowledge property guarantees that *B* will learn nothing that could help him to later falsely impersonate *A*.

The zero-knowledge property is achieved by designing a dialogue that can be simulated by the verifier alone. This intuitively proves that the verifier will learn nothing from the claimant in terms of properties of the private key, which the verifier could not have obtained from the corresponding public key.

It also means that an observer to the exchange of messages making up the mechanism will be unable to decide if the claimant really was involved, or the verifier simulated the exchange.

Zero-knowledge mechanisms by nature require the use of asymmetric cryptographic techniques. Given the strict definition of a zero-knowledge mechanism, it is actually not possible to implement one. In fact, a much better description of the mechanisms in this part of ISO/IEC 9798 would be secrecy-preserving mechanisms. However, the concept of zero-knowledge mechanism is part of a well-known and established theory in cryptography, for which reason the terminology is used here.

### B.3 Definitions

Going a little closer to a formal definition, a zero-knowledge mechanism takes place between two parties, a claimant  $A$  and a verifier  $B$ . The claimant tries to convince the verifier that a certain statement is true. For example, this statement could be "I know the private key corresponding to  $P_A$ ". To convince  $B$ , the claimant and verifier exchange messages for a while, after which  $B$  decides to accept or reject  $A$ 's proof.

Three essential properties are needed for such a mechanism.

**Completeness.** If  $A$ 's statement is true, then  $B$  should accept it with overwhelming probability.

**Soundness.** If  $A$ 's statement is false, then no matter how  $A$  behaves,  $B$  should reject it with overwhelming probability.

**Zero-knowledge.** No matter how  $B$  behaves, he receives only the information that  $A$ 's statement is true. A little more precisely: whatever  $B$  receives when talking to a truthful claimant,  $B$  could just as easily compute himself without talking to  $A$  at all. What this means is that  $B$  can simulate the conversation by himself, producing a conversation that looks exactly as if it had been produced by talking to  $A$ .

### B.4 Example

Consider the following example, which is a simplified version of an FS mechanism<sup>[4]</sup>. Here, we are given a modulus  $n$  and a number modulo  $n$ , named  $G$ . In this case,  $A$ 's statement is "I know a modular square root of  $G$ ". Note that  $Q$  is a modular square root of  $G$ , if and only if  $Q^2 \bmod n \equiv G$ .

The conversation between  $A$  and  $B$  goes as follows.

- $A$  chooses a fresh random number  $r$ , non-zero and less than  $n$ , squares it modulo  $n$  and sends the modular square  $W$  to  $B$ .
- $B$  chooses a fresh random bit  $d$ , i.e. either 0 or 1, and sends it to  $A$  as a challenge.
- If  $d$  is equal to zero, then the response is  $D = r$ . If  $d$  is equal to one, the response is  $D = r \times Q \bmod n$ .  $A$  sends the response  $D$  to  $B$ .
- $B$  first checks that  $D$  is a non-zero number less than  $n$ ; if  $D$  is zero,  $n$  or more, then  $B$  rejects  $A$  and aborts the procedure.
- If  $d$  is equal to zero, then  $B$  checks that the modular square of  $D$  is identical to  $W$ . If  $d$  is equal to one, then  $B$  checks that the modular square of  $D$  is identical to  $W \times G \bmod n$ .
- If the check is correct, then continue the procedure, else  $B$  rejects  $A$  and aborts the procedure.

The procedure completes successfully after  $t$  consecutive successful iterations.

It is not too difficult to see that if both  $A$  and  $B$  follow this procedure, then  $B$  will never reject  $A$ ; squaring  $D$  means squaring either  $r$  or  $r \times Q \bmod n$ , which will give the result  $W$  or  $W \times G \bmod n$ .

On the other hand, if in any of the  $t$  iterations,  $A$  is able to give a correct answer to both  $d = 0$  and  $d = 1$ , this means that  $A$  can provide both  $D_0$  and  $D_1$ . As a matter of fact,  $D_1 / D_0 \bmod n$  is a modular square root of  $G$  and therefore the statement that " $A$  knows a modular square root of  $G$ " is true. But conversely, if  $A$  is cheating and does not know a modular square root of  $G$ , he shall be unable to answer at least one value of  $d$  correctly in each of the  $t$  iterations. Therefore the probability that a cheating claimant convinces the verifier is at most  $2^{-t}$ . For example, by doing 20 iterations, we reduce this chance to about 1 in a million. Such a value is named "mechanism security level" (see also C.1.4). Thus the soundness property is also satisfied.

As for zero-knowledge, note that, after the conversation is over, the verifier is left with two numbers  $D$  and  $W$ , so that  $D^2 \bmod n$  is equal to either  $W$  or  $G W \bmod n$ . But this is indeed something that the verifier could make himself without talking to  $A$ . To do this,  $B$  just chooses a random number  $D$  and defines  $W$  either as  $D^2$  or as  $D^2 / G \bmod n$ . The fact that  $W$  and  $D$  are, in this case, computed in a way different from the way the claimant would compute them is insignificant; they are distributed in exactly the same way, i.e. it is impossible to tell the difference. Therefore,  $B$  learns nothing he could not compute himself, except for the fact that  $A$  knows a modular square root of  $G$ .

Let us anticipate here a frequently asked question. If the verifier can make good looking conversations himself, without knowing a root of  $G$ , why should he be convinced when the claimant produces a similar conversation? The answer is that when  $B$  simulates the protocol, he is free to produce the numbers in a backwards direction, i.e. to first choose  $D$  and then compute a  $W$  that fits. In a real protocol execution,  $A$  does not have this opportunity. The verifier expects to see  $W$  before  $d$  is selected, and then the claimant shall find a correct  $D$ .

Although we have glossed over a couple of technical difficulties here, these are the essentials of the argument why a mechanism has the zero-knowledge property.

## B.5 Basic design principles

The example from the previous section covers one of two basic design ideas that underlie almost all known zero-knowledge mechanisms, namely:

- The claimant  $A$  sends a witness to the verifier  $B$ . Then  $B$  asks  $A$  one out of some set of questions. If  $A$  is cheating, he cannot answer all possible questions, so we have some chance of catching him. On the other hand,  $A$  never answers more than one question, and this one answer alone reveals nothing to the verifier.

This design idea forms the basis of the mechanisms specified in clauses 5, 6, 7 and 8.

The other design idea, and one which forms the basis of the mechanism specified in clause 9, is based on the following:

- The verifier asks the claimant a question, for which the verifier already knows the answer. The protocol shall ensure that this really is the case. If  $A$  is honest, he can easily compute the right answer, but if he is cheating, he can do no better than guess at random, and will be incorrect most of the time.
- On the other hand, when  $B$  receives the answer, he already knows what  $A$  will say, and therefore the mechanism has the zero-knowledge property.

One easy example of this is when  $A$  shall prove possession of a private key in a public-key system. The verifier can encipher a random message under  $A$ 's public key, and ask  $A$  to return the deciphered message. Only the user knowing the correct private key can do this. To get the zero-knowledge property, we shall ensure that  $B$  really knows the message in advance. This part of ISO/IEC 9798 contains an example of one way to do this, namely  $B$  can be asked to reveal some information (the witness) related to the message.

The bibliography indicates a comprehensive approach of zero-knowledge protocols <sup>[20]</sup> and a formal basis for a rigorous understanding of zero-knowledge protocols <sup>[3][10]</sup>.

## Annex C (informative)

### Guidance on parameter choice and comparison of the mechanisms

#### C.1 Guidance on parameter choice

##### C.1.1 Modulus sizes

In this part of ISO/IEC 9798, every authentication mechanism makes use of a modulus that is either prime (for the SC mechanism) or composite (for any other mechanism).

In 1995, Odlyzko<sup>[18]</sup> estimated the future of integer factorization and discrete logarithms. *"With the present state of knowledge, discrete logarithms are slightly more difficult to compute modulo an appropriately chosen prime than it is to factor a hard integer of the same size, but the difference is not large. Therefore, to be on the safe side in designing cryptosystems, one should assume that all the projections about sizes of integers that it will be possible to factor will also apply to sizes of primes modulo which one can compute discrete logarithms."*

As a conclusion at the end of the quoted article<sup>[18]</sup>, Kaliski stressed the importance of variable key sizes in the implementations and provided recommendations on modulus sizes.

- Short term security: 768 bits.
- Medium term security: 1024 bits.
- Long term security: 2048 bits.

For a comprehensive analysis of key lengths, see also Silverman<sup>[22]</sup>, and Lenstra and Verheul<sup>[14]</sup>.

##### C.1.2 Composite modulus and prime factors

Throughout the standard, the distinct large prime factors are denoted  $p_1, p_2, \dots$  in ascending order, the modulus is set equal to the product of the prime factors, i.e.  $n = p_1 \times p_2 \times \dots$  and  $\alpha$  denotes the bit size of the modulus, i.e.  $2^{\alpha/2} / 2 < n < 2^{\alpha}$ . Moreover, the standard states that, if  $\alpha$  is a multiple of the number of prime factors, denoted  $f$ , then the bit size of every prime factor shall be  $\alpha/f$ , i.e.  $2^{\alpha/f/2} / 2 < p_1 \dots < p_f < 2^{\alpha/f}$ .

NOTE 1 ISO/IEC 18032<sup>[29]</sup> specifies how to select large prime numbers.

The following method defines successive variable intervals for successively selecting large prime factors, the bit size of which is  $\alpha/f$ . Hereafter the current value of the product of the prime factors is denoted  $z$ .

- The first prime factor is selected within the interval from  $2^{\alpha/f/2} / 2$  to  $2^{\alpha/f}$ . The initial value of  $z$  is set equal to the first prime factor.
- This step is repeated  $f-1$  times. A new prime factor is selected within the interval from  $(2^{\lfloor \log_2 z \rfloor} / z) \times 2^{\alpha/f/2}$  to  $2^{\alpha/f}$ . The current value of  $z$  is multiplied by the new prime factor.
- The prime factors are denoted  $p_1$  to  $p_f$  in ascending order and the modulus  $n$  is set equal to the final value of  $z$ .

The following method defines a single fixed interval, slightly reduced, for selecting every prime factor.

- Every prime factor is selected within the interval from  $\beta \times (2^{\alpha/f})$  to  $2^{\alpha/f}$  where  $\beta$  denotes the  $f$ -th root of  $1/2$ .

NOTE 2 The value of  $\beta$  may be approximated by a rational number greater than  $\beta$  (e.g.  $5/7$  for the square root of  $1/2$ ,  $4/5$  for the cube root of  $1/2$ ).

### C.1.3 Lengths of fresh strings of random bits for representing random numbers

In the mechanisms specified in Clauses 5 to 8, the claimant converts any random number  $r$  into a witness  $W$  in accordance with a witness formula and then produces a response  $D$  to any challenge  $d$  in accordance with a response formula. The procedure parameters  $W$ ,  $d$  and  $D$  together form a zero-knowledge proof, i.e. a triple denoted  $\{W, d, D\}$  satisfying a verification formula. The set of proofs forms a family of  $d$  permutations of the set of, or a subset of, the integers with respect to the modulus; this set of integers is either a field, or a ring.

As any third party can use the verification formula for computing a witness  $W$  from any challenge  $d$  and response  $D$  selected at random, i.e. for producing triples at random, it is important that the set of triples is so large that the advantage obtained by producing in advance as many triples as possible remains negligible.

It is important that the claimant chooses random numbers in such a way that the probabilities of guessing them and the same number being selected twice within the claimant's lifetime are negligible. If, for example, a claimant uses twice the same random number, then he will produce an "interlocked" pair of triples, i.e. responses to two challenges for the same non-zero witness, denoted  $\{W, d_1, D_1\}$  and  $\{W, d_2, D_2\}$ .

- In the FS mechanisms, as any interlocked pair of triples provides a modular multiplicative combination of private keys, any third party will improve its performances for impersonating the claimant.
- In the GQ1, SC and GPS mechanisms, as any interlocked pair of triples provides the private key. With the private key, any third party is able to impersonate the claimant.
- In the GQ2 mechanisms, the key production ensures that, for any values of  $m$  and  $k$ , more than one half of all the interlocked pairs of triples reveals a non-trivial modular square root of 1. The knowledge of such a number induces the knowledge of a decomposition of the modulus, i.e. the factorization if there are two factors. With the factorization, any third party is able to impersonate the claimant.

On receipt of  $\text{TokenAB}_i$ , i.e. either a witness  $W$ , or a hash-code of  $W$  and  $\text{Text}$ , the verifier produces a challenge  $d$  at random. It is important that all the possible challenges are equally probable and hence the challenge is unpredictable. Any cheater can succeed in a masquerade by guessing the challenge in advance. If  $2^\delta$  challenges are equally probable, then the probability of success of a cheater is one chance out of  $2^\delta$ .

In the mechanisms specified in Clause 9, there is no witness. The verifier constructs a number  $d$  from a random parameter  $r$  that is the response  $D$ . The numbers  $d$  and  $D$  together form a proof denoted  $\{d, D\}$ . Such a proof is of "zero-knowledge type". The set of proofs is a very small fraction of the RSA permutation, much smaller than the sets of proofs used in the mechanisms specified in Clauses 5 to 8. It is important that the verifier chooses random parameters in such a way that the probabilities of guessing them and re-using them are negligible. Any third party can use the public operation for producing pairs at random. It is important that the set of pairs is so large that the advantage obtained by producing in advance as many pairs as possible remains negligible.

As a conclusion, the length of the fresh strings of random bits for representing random numbers is set equal to

- $\alpha$  bits in FS, GQ1 and GQ2.
- $|q|$  bits in SC (typically,  $|q| = 160$ ).
- $\sigma + \delta + 80$  bits in GPS1 (typically,  $\sigma = 160$ ).
- $\alpha + \delta + 80$  bits in GPS2.
- at least  $2 \times |h|$ , but less than  $\alpha - |h|$  bits in  $\text{RSA}_{\text{UA}}$  (typically,  $|h| = 160$ ).
- at least  $2 \times |h|$ , but less than  $0,5 \times (\alpha - |h| - |ID|)$  bits in  $\text{RSA}_{\text{MA}}$  (typically,  $|h| = 160$  and  $|ID| = 40$ ).

### C.1.4 Strategies for the use of the various mechanisms

This clause considers four groups of mechanisms in accordance with the analysis of the formula complexities.

- a) FS, GQ1 and GQ2, i.e. the mechanisms specified in Clauses 5 and 6;
- b) SC, GPS1 and GPS2, i.e. the mechanisms specified in Clauses 7 and 8;
- c)  $\text{RSA}_{\text{UA}}$ , i.e. the mechanisms specified in Clause 9.2.
- d)  $\text{RSA}_{\text{MA}}$ , i.e. the mechanisms specified in Clause 9.3.

**NOTE** Consider a portable device so that power analysis distinguishes squaring and multiplying. In order to keep the exponents secret, countermeasures are needed for implementing the SC and GPS witness formulae and the private RSA operation. But as the exponents are public in the FS and GQ witness and response formulae, the implementation is straightforward.

In the FS, GQ1 and GQ2 mechanisms, the witness is the modular  $v$ -th power of a random number  $r$ . The verification exponent  $v$  is short (up to 40 bits). The witness formula is a **short modular exponentiation**. The response formula is also a short, possibly combined, modular exponentiation; it allows trade-offs between computational complexity and storage requirement. Nevertheless, the response formula and the witness formula have a similar complexity. The verification formula is a short combined modular exponentiation; it induces a verifier workload similar to the claimant workload.

- The FS, GQ1 and GQ2 mechanisms are attractive in systems where the claimant and the verifier have similar performances. For example, if the claimant is a smart card, then, as the verifier workload and the claimant workload are similar, the computational power of the smart card is sufficient for a verifier. Consequently, a payment card and a merchant card may authenticate each other, either locally through a payment terminal, or even remotely through the Internet.

In the FS, GQ1 and GQ2 mechanisms, the challenge size has to be optimized: the least the challenge, the shortest the modular exponentiations. For example, there are  $2^{k \times m}$  possible GQ2 challenges.

- One chance out of  $2^{36}$  may be an adequate security level in a high security environment, e.g. either  $k = 18$  and two basic numbers, or  $k = 12$  and three basic numbers, or  $k = 6$  and six basic numbers.
- One chance out of  $2^{24}$  may be an adequate security level through the Internet, e.g. either  $k = 12$  and two basic numbers, or  $k = 8$  and three basic numbers, or  $k = 4$  and six basic numbers.
- One chance out of 65 536 may be an adequate security level for deterring "yes cards" on automated paying machines seizing rejected cards, e.g. either  $k = 8$  and two basic numbers, or  $k = 4$  and four basic numbers, or  $k = 2$  and eight basic numbers.
- One chance out of 4 may be an adequate security level for deterring pirate cards periodically (every few seconds) on "official" pay TV decoders, e.g.  $k = 1$  and two basic numbers.

In the SC and GPS mechanisms, the witness is the modular  $r$ -th power of a base  $g$ . The random number  $r$  is medium (e.g. 160 bits for the SC mechanisms, 248 to 280 bits for the GPS1 mechanisms,  $\alpha + 88$  to  $\alpha + 120$  bits for the GPS2 mechanisms). The witness formula is a **medium or long modular exponentiation**.

In the SC and GPS mechanisms, the complexity of the response formula is negligible in comparison with that of the witness formula. As the computation of  $\text{TokenAB}_i$  needs no interaction with a verifier, a set of coupons ( $r$ ,  $\text{TokenAB}_i$ ) can be computed in advance and stored in the claimant. Additionally, if  $r$  is pseudo-randomly produced,  $r$  needs not be stored as it can be reproduced. The verification formula is a medium double modular exponentiation or a long modular exponentiation; it induces a verifier workload similar to the claimant workload. The challenge size may be optimized, but without any practical impact on the complexity of the witness and verification formulae.

- The SC and GPS mechanisms are attractive in systems where "coupons" can be prepared in advance for the claimant and where the interaction with a powerful verifier has to be as quick as possible. For example, a device without computational power (e.g. a tag) can quickly answer.

In the  $\text{RSA}_{\text{UA}}$  mechanisms, the verifier computes the challenge by a **short modular exponentiation** and then, the claimant computes the response by a **long modular exponentiation**. As the challenge has to be large, there is no room at all for optimization in relation with the challenge size. As the computation of  $\text{TokenBA}$  needs no interaction with the claimant, a set of coupons ( $r$ ,  $\text{TokenBA}$ ) can be computed in advance and stored in the verifier. Additionally, if  $r$  is pseudo-randomly produced,  $r$  needs not be stored as it can be reproduced.

- The  $\text{RSA}_{\text{UA}}$  mechanisms are attractive in systems where "coupons" can be "securely" prepared in advance for verifiers interacting with a powerful claimant. For example, a device without computational power (e.g. a tag) can authenticate a powerful computer.

In the  $\text{RSA}_{\text{MA}}$  mechanisms, both entities have to compute a short modular exponentiation and a long modular exponentiation. There is no possibility of a "coupon" strategy for such mechanisms.

## C.2 Comparison of the authentication mechanisms

### C.2.1 Symbols and abbreviated terms

The comparison uses the following measures: the storage required in the claimant, the complexity of the computations carried out by the claimant, the complexity of the computations carried out by the verifier, and the communications required between the claimant and the verifier.

NOTE If the claimant is a portable device (e.g. a smart card), then the complexity of computation and the required communication and storage may be crucial, since the processing and storage capacities of smart cards are very limited in comparison with those allowed for the verifier.

For the purposes of this annex, the following symbols and abbreviated terms apply.

|              |  |
|--------------|--|
| <i>ChC</i>   | computational complexity of a CRT composition  |
| <i>ChD</i>   | computational complexity of a CRT decomposition  |
| <i>CM</i>    | communication required between the claimant and the verifier ( $CM_h$ when using a hash-function)      |
| <i>CPC</i>   | complexity of the computations carried out by the claimant   |
| <i>CPV</i>   | complexity of the computations carried out by the verifier   |
| <i>Cr</i>    | CRT coefficient  |
| <i>CS</i>    | storage required in the claimant   |
| <i>HW(v)</i> | number of bits set to 1 in the binary representation of number $v$ , e.g. $HW(65\ 537 = 2^{16}+1) = 2$ |
| $M_\alpha$   | computational complexity of a modular multiplication ( $\alpha$ is the bit size of the modulus)        |
| $X_\alpha$   | computational complexity of a modular square ( $\alpha$ is the bit size of the modulus)                |

### C.2.2 Complexity of modular operations

This clause evaluates the computational complexity of modular operations, namely the modular multiplication, the modular square, the modular exponentiation and the combined modular exponentiation.

The **modular multiplication** is defined as  $A \times B \bmod C$ . It may be performed as two consecutive operations: a multiplication followed by a reduction. In accordance with the experience, the workload due to a multiplication is approximately equal to the workload due to a reduction.

- When  $A$  and  $B$  have the same size as  $C$ , a multiplication provides a result twice longer than  $C$ .
- A reduction provides the remainder of the division of the result by  $C$ .

When  $A$  and  $B$  have the same size as  $C$ , the modular multiplication complexity is denoted  $M_{|C|}$ .

If number  $n$  is  $f$  times longer than number  $p$ , i.e. if  $n$  and  $p^f$  have the same size, i.e.  $|n| = f \times |p|$ , then the ratio between a multiplication modulo  $n$  and a multiplication modulo  $p$  is approximately  $f^2$  ( $M_{|n|} \approx f^2 \times M_{|p|}$ ). Consequently, the value of  $M_{|C|}$  is proportional to  $|C|^2$ .

For example, if  $n$  is twice longer than  $p$ , i.e.  $|n| = 2 \times |p|$ , then  $M_{|n|} \approx 4 \times M_{|p|}$ .

The **modular square** is defined as  $A^2 \bmod C$ . It may be performed as two consecutive operations: a square followed by a reduction.

- When  $A$  has the same size as  $C$ , the square provides a result twice longer than  $C$ . According to Menezes, van Oorschot and Vanstone<sup>[16]</sup>, the complexity of the square is half that of the multiplication.

NOTE As  $A \times B = ((A+B)^2 - (A-B)^2) / 4$ , the multiplication may result from using twice a squaring routine.

- The reduction provides the remainder of the division of the result by  $C$ . The complexity of this operation is as above.

When  $A$  has the same size as  $C$ , the modular square complexity is denoted  $X_{|C|}$ .

$$X_{|C|} \approx 0,75 \times M_{|C|}$$

The **modular exponentiation** is defined as  $A^B \bmod C$ . It may be performed as the right to left version of the square and multiply algorithm<sup>[13][16]</sup>, i.e.  $|B|-1$  modular squares and  $HW(B)-1$  modular multiplications by  $A$ .

The **combined modular exponentiation** is defined as  $A_1^{B_1} \times \dots \times A_x^{B_x} \bmod C$ . It may be performed as  $\max\{|B_1|, \dots, |B_x|\}-1$  modular squares and  $HW(B_1) + \dots + HW(B_x) - 1$  modular multiplications by  $A_i$ .

- If  $A_i$  is small (i.e.  $|A_i| \leq 8$ ), then the modular multiplications due to  $B_i$  are negligible in comparison with the modular squares.
- Depending upon whether the bit size of the exponent, i.e.  $\max\{|B_1|, \dots, |B_x|\}$ , is either small, i.e. up to 40, or medium, i.e. {160, 240 to 280}, or large, i.e.  $\{|C|, |C|+80 \text{ to } |C|+120\}$ , the modular exponentiation is either short, or medium, or long.

### C.2.3 CRT technique

This clause defines the CRT technique, i.e. the use of the Chinese Remainder Theorem.

Consider two numbers  $x_1 < x_2$ , co-prime, but not necessarily prime, and their product denoted  $x$ .

NOTE The CRT technique accommodates any number of prime factors. Consider two distinct prime factors  $p_1 < p_2$  and their product  $p_1 \times p_2$ , and then three distinct prime factors  $p_3 < (p_1 \times p_2)$  and their product  $(p_1 \times p_2) \times p_3$ , and so on.

By definition, the CRT coefficient is the positive integer  $Cr$  less than  $x_1$  so that  $x_1$  divides  $Cr \times x_2 - 1$ .

By definition, the CRT composition converts any pair of components, namely  $X_1$  from  $\{0, 1, \dots, x_1-1\}$  and  $X_2$  from  $\{0, 1, \dots, x_2-1\}$ , into the corresponding unique number  $X$  from  $\{0, 1, \dots, x-1\}$ . It makes use of the two numbers  $x_1$  and  $x_2$  and the CRT coefficient  $Cr$  as follows.

$$Y = X_1 - X_2 \bmod x_1; Z = Y \times Cr \bmod x_1; X = Z \times x_2 + X_2$$

The CRT composition consists of a modular multiplication modulo a factor and one multiplication of two numbers with the same size as a factor, resulting in a number with the same size as the modulus. When the two factors have the same size, e.g.  $|p_1| = |p_2| = |n| / 2$ , the composition complexity is denoted  $ChC$ .

$$ChC \approx 1,5 \times M_{|p|} \approx (3/8) \times M_{|n|}$$

Any number  $X$  from  $\{0, 1, \dots, x-1\}$  is decomposed into a pair of components, namely  $X_1$  from  $\{0, 1, \dots, x_1-1\}$  and  $X_2$  from  $\{0, 1, \dots, x_2-1\}$ , as follows. Decomposition reverses composition and vice versa.

$$X_1 = X \bmod x_1 \quad \text{and} \quad X_2 = X \bmod x_2$$

The decomposition consists of two reductions modulo a factor. When the two factors have the same size, e.g.  $|p_1| = |p_2| = |n| / 2$ , the decomposition complexity is denoted  $ChD$ .

$$ChD \approx M_{|p|} \approx 0,25 \times M_{|n|}$$

For example, the CRT technique reduces the complexity of a private RSA operation from a long modular exponentiation mod  $n$  (i.e.  $(5/4) \times |n| \times M_{|n|}$ ) to one  $ChD$  plus two long modular exponentiations mod  $p_i$  (with exponents reduced mod  $p_i-1$ ) plus one  $ChC$  (i.e.  $(1+2,5 \times |p|+1,5) \times M_{|p|} = 2,5 \times (|p|+1) \times M_{|p|}$ ). As  $|n| = 2 \times |p|$ ,  $M_{|n|} \approx 4 \times M_{|p|}$  and the reduced complexity is  $\approx (5/16) \times |n| \times M_{|n|}$ .

### C.2.4 Complexity analysis

#### C.2.4.1 FS

The claimant stores  $n$  and  $Q_1$  to  $Q_m$ .

Witness formula  $W = r^2 \bmod^* n$

Response formula  $D = r \times \prod_{i=1}^m Q_i^{d_i} \bmod^* n$

For  $t$  iterations, as  $HW(d) \approx m / 2$  in average,

Verification formula  $W^* = D^2 \times \prod_{i=1}^m G_i^{d_i} \bmod^* n$

For  $t$  iterations, as  $HW(d) \approx m / 2$  in average,

Token $AB_1$  = either  $W$  as  $|n|$  bits or a hash-code as  $|h|$  bits;  $d$  as  $m$  bits; Token $AB_2 = D$  as  $|n|$  bits.

For  $t$  exchanges,  $CM$  (bits)  $\approx t \times (2 \times \alpha + m)$

$CS$  (bits)  $= (m + 1) \times |n| = (m + 1) \times \alpha$

i.e.  $X_{|n|}$

i.e.  $HW(d) \times M_{|n|}$

$CPC$  ( $M_\alpha$ )  $\approx t \times (2 \times m + 3) / 4$

i.e.  $X_{|n|} + HW(d) \times M_{|n|}$

$CPV$  ( $M_\alpha$ )  $\approx t \times (2 \times m + 3) / 4$

$CM_h$  (bits)  $\approx t \times (\alpha + |h| + m)$

#### C.2.4.2 GQ1

The claimant stores  $n$ ,  $v$  and  $Q$ .

Witness formula  $W = r^v \bmod n$

Response formula  $D = r \times Q^d \bmod n$

As  $d$  is from  $\{0, 1, \dots, v-1\}$ , i.e.  $|d| = |v|$  and  $HW(d) = |v| / 2$ ,

Verification formula  $W^* = D^v \times G^d \bmod n$

As  $HW(d) = |v| / 2$ ,

Token $AB_1 = W$  as  $|n|$  bits or a hash-code as  $|h|$  bits;  $d$  as  $|v|$  bits; Token $AB_2 = D$  as  $|n|$  bits.

$CM$  (bits)  $\approx 2 \times \alpha + |v|$

$CS$  (bits)  $= 2 \times |n| + |v| = 2 \times \alpha + |v|$

i.e.  $(|v| - 1) \times X_{|n|} + (HW(v) - 1) \times M_{|n|}$

i.e.  $M_{|n|} + (|d| - 1) \times X_{|n|} + (HW(d) - 1) \times M_{|n|}$

$CPC$  ( $M_\alpha$ )  $\approx 2 \times |v| + HW(v) - 2,5$

i.e.  $(|v| - 1) \times X_{|n|} + (HW(d) + HW(v) - 1) \times M_{|n|}$

$CPV$  ( $M_\alpha$ )  $\approx 1,25 \times |v| + HW(v) - 1,75$

$CM_h$  (bits)  $\approx \alpha + |h| + |v|$

#### C.2.4.3 GQ2

The claimant stores  $p_1, p_2, Cr$  and  $Q_{1,1}$  to  $Q_{m,2}$ .

Witness formula  $W_j = r_j^{2^{k+b}} \bmod p_j$

Response formula  $D_j = r_j \times \prod_{i=1}^m Q_{i,j}^{d_i} \bmod p_j$

As  $ChC \approx 1,5 M_{|p|}$ ,

As  $M_{|p|} \approx M_{|n|} / 4$ ,

Verification formula  $W^* = D^{2^{k+b}} \times \prod_{i=1}^m G_i^{d_i} \bmod n$

As the basic numbers are small,

Token $AB_1 = W$  as  $|n|$  bits or a hash-code as  $|h|$  bits;  $d$  as  $k \times m$  bits; Token $AB_2 = D$  as  $|n|$  bits.

$CM$  (bits)  $\approx 2 \times \alpha + k \times m$

$CS$  (bits)  $= (m + 1,5) \times |n| = (m + 1,5) \times \alpha$

i.e.  $2 \times (k + b) \times X_{|p|} + ChC$

i.e.  $2 \times ((k-1) \times X_{|p|} + 0,5 \times k \times m \times M_{|p|}) + ChC$

$\approx (3 + (k + (b-1)/2) \times (m + 3)) \times M_{|p|}$

$CPC$  ( $M_\alpha$ )  $\approx (k + (b-1)/2) \times (m + 3) / 4 + 0,75$

i.e.  $(k + b) \times X_{|n|}$

$CPV$  ( $M_\alpha$ )  $\approx 0,75 \times (k + b)$

$CM_h$  (bits)  $\approx \alpha + |h| + k \times m$

#### C.2.4.4 SC

The claimant stores  $p, q, g$  and  $Q$ .

Witness formula  $W = g^r \bmod p$

Response formula  $D = r - d \times Q \bmod q$

$CS$  (bits)  $= 2 \times (|p| + |q|) = 2 \times (\alpha + |q|)$

i.e.  $(|r| - 1) \times X_{|p|} + (HW(r) - 1) \times M_{|p|}$

negligible

As  $|r| = |q|$  and  $HW(r) = |q|/2$ ,

Verification formula  $W^* = g^D \times G^d \text{ mod } p$

As  $HW(d) = \delta/2$ ,  $|D| = |q|$  and  $HW(D) = |q|/2$ ,

TokenAB<sub>1</sub> = either  $W$  as  $|p|$  bits or a hash-code as  $|h|$  bits;  $d$  as  $\delta$  bits; TokenAB<sub>2</sub> =  $D$  as  $|q|$  bits.

$$CM \text{ (bits)} \approx \alpha + |q| + \delta$$

$$CPC (M_\alpha) \approx 1,25 \times |q|$$

$$\text{i.e. } (|D|-1) \times X_{|p|} + (HW(D) + HW(d) - 1) \times M_{|p|}$$

$$CPV (M_\alpha) \approx 1,25 \times |q| + 0,5 \times \delta$$

$$CM_h \text{ (bits)} \approx |h| + |q| + \delta$$

#### C.2.4.5 GPS1

**Without CRT**, the claimant stores  $n$  and  $Q$ .

Witness formula  $W = g^r \text{ mod } n$  where  $g = 2$ ,

Response formula  $D = r - d \times Q$

As  $|r| = \rho = \sigma + \delta + 80$ ,

**With CRT**, the claimant stores  $p_1, p_2, Cr$  and  $Q$ .

Witness formula  $W_j = g^r \text{ mod } p_j$  where  $g = 2$ ,

Response formula  $D = r - d \times Q$

As  $|r| = \rho$  and  $< 0,5 \times |n|$  and  $ChC \approx 1,5 \times M_{|p|}$

As  $M_{|p|} \approx M_{|n|} / 4$  and  $\rho = \sigma + \delta + 80$ ,

Verification formula  $W^* = g^D \times G^d \text{ mod } n$

As  $HW(d) = \delta/2$  and  $|D| = \rho$ ,

TokenAB<sub>1</sub> = either  $W$  as  $|n|$  bits or a hash-code as  $|h|$  bits;  $d$  as  $\delta$  bits; TokenAB<sub>2</sub> =  $D$  as  $\rho = \sigma + \delta + 80$  bits.

$$CM \text{ (bits)} \approx \alpha + \sigma + 2 \times \delta + 80$$

$$CS \text{ (bits)} = |n| + |Q| = \alpha + \sigma$$

$$\text{i.e. } (|r|-1) \times X_{|n|}$$

negligible

$$CPC (M_\alpha) \approx (3/4) \times (\sigma + \delta) + 60$$

$$CS \text{ (bits)} = 1,5 \times |n| + |Q| = 1,5 \times \alpha + \sigma$$

$$\text{i.e. } 2 \times (|r|-1) \times X_{|p|} + ChC$$

negligible

$$\approx 1,5 \times \rho \times M_{|p|}$$

$$CPC (M_\alpha) \approx (3/8) \times (\sigma + \delta) + 30$$

$$\text{i.e. } (|D|-1) \times X_{|n|} + (HW(d) - 1) \times M_{|n|}$$

$$CPV (M_\alpha) \approx 0,75 \times \sigma + 1,25 \times \delta + 60$$

$$CM_h \text{ (bits)} \approx |h| + \sigma + 2 \times \delta + 80$$

#### C.2.4.6 GPS2

**Without CRT**, the claimant stores  $n$  and  $Q$ .

Witness formula  $W_j = G^{r \times v} \text{ mod } n$  where  $G = 2$ ,

Response formula  $D = r - d \times Q$

**With CRT**, the claimant stores  $p_1, p_2, Cr$  and  $Q$ .

Witness formula  $W_j = G^{r \times v \text{ mod } p_j - 1} \text{ mod } p_j$  where  $G = 2$ ,

Response formula  $D = r - d \times Q$

As  $2 \times |p| = |n|$  and  $ChC \approx 1,5 \times M_{|p|}$ ,

As  $M_{|p|} \approx M_{|n|} / 4$ ,

Verification formula  $W^* = G^{d+v \times D} \text{ mod } n$

As  $|D \times v| = \rho$ ,  $HW(D \times v) = \rho/2$  and  $\rho = \alpha + \delta + 80$ ,

TokenAB<sub>1</sub> = either  $W$  as  $|n|$  bits or a hash-code as  $|h|$  bits;  $d$  as  $\delta$  bits; TokenAB<sub>2</sub> =  $D$  as  $\rho = \alpha + \delta + 80$  bits.

$$CM \text{ (bits)} \approx 2 \times \alpha + 2 \times \delta + 80$$

$$CS \text{ (bits)} = 2 \times |n| = 2 \times \alpha$$

$$\text{i.e. } (|r| + |v|) \times X_{|n|}$$

negligible

$$\approx (|n| + 2 \times \delta + 80) \times 0,75 \times M_{|n|}$$

$$CPC (M_\alpha) \approx (3/4) \times (\alpha + 2 \times \delta + 80)$$

$$CS \text{ (bits)} = 2,5 \times |n| = 2,5 \times \alpha$$

$$\text{i.e. } 2 \times (|p|-1) \times X_{|p|} + ChC$$

negligible

$$\approx |n| \times 0,75 \times M_{|p|}$$

$$CPC (M_\alpha) \approx (3/16) \times \alpha$$

$$\text{i.e. } (|D \times v| - 1) \times X_{|n|} + (HW(D \times v) - 1) \times M_{|n|}$$

$$CPV (M_\alpha) \approx 1,25 \times (\alpha + \delta) + 100$$

$$CM_h \text{ (bits)} \approx \alpha + |h| + 2 \times \delta + 80$$

**C.2.4.7 RSA<sub>UA</sub>**

The claimant retains  $p_1, p_2, s_1, s_2$  and  $Cr$ .

Public RSA operation:  $P_X(m) = m^v \text{ mod } n$

For example, if  $v$  is set equal to  $2^{16}+1$ ,

Private RSA operation using the CRT technique

Token<sub>BA</sub> =  $d$  as  $|n|$  bits; Token<sub>AB</sub> =  $r^*$  as  $|n| - |h|$  bits.

$$CS \text{ (bits)} = 2,5 \times |n| = 2,5 \times \alpha$$

$$\text{i.e. } (|v|-1) \times X_{|n|} + (HW(v)-1) \times M_{|n|}$$

$$CPV(M_\alpha) \approx 0,75 \times |v| + HW(v) - 1,75$$

$$CPV(M_\alpha) \approx 13$$

$$CPC(M_\alpha) \approx (5/16) \times \alpha$$

$$CM \text{ (bits)} \approx 2 \times \alpha - |h|$$

**C.2.4.8 RSA<sub>MA</sub>**

Each entity retains  $p_1, p_2, s_1, s_2$  and  $Cr$ .

Each entity performs a private RSA operation and a public RSA operation.

$$CS \text{ (bits)} = 2,5 \times |n| = 2,5 \times \alpha$$

$$CPC(M_\alpha) \approx CPV(M_\alpha) \approx 13 + (5/16) \times \alpha$$

Token<sub>BA<sub>1</sub></sub> =  $d$  as  $|n|$  bits; Token<sub>AB</sub> =  $d^*$  as  $|n|$  bits; Token<sub>AB<sub>2</sub></sub> =  $rr^{**}$  as  $0,5 \times (|n| - |h| - |ID|)$  bits.

$$CM \text{ (bits)} \approx 2,5 \times \alpha - 0,5 \times |h| - 0,5 \times |ID|$$

**C.2.4.9 Summary of the evaluations**

Table C.1 summarizes the evaluations detailed in C.2.4.1 to C.2.4.8. In the FS, GQ, SC and GPS mechanisms, the required communication is either  $CM$  or  $CM_h$ . Such a distinction is not relevant in the RSA mechanisms. In the GPS mechanisms, the use of the CRT technique by the claimant is evaluated for  $CS$  and  $CPC$ . Table C.1 is used in C.2.5 for  $\alpha = 1024$ ,  $|h| = 160$  (e.g. RIPEMD-160 and SHA-1) and  $|ID| = 40$  with different values of the security level.

**Table C.1 — Summary of the evaluations**

## Annex D (informative)

### Numerical examples

#### D.1 FS mechanism

##### D.1.1 Key production

##### D.1.1.1 Asymmetric key pair ( $v = 2$ , the Rabin scheme)

The bit size is 512 for each prime factor and  $\alpha = 1024$  for the modulus. As the verification exponent is  $v = 2$ , one prime factor is congruent to 3 mod 8 and the other one to 7 mod 8.

```

##### D.1.1.2 Identification data and asymmetric pairs of numbers

The pair multiplicity parameter is  $m = 8$ . Each part of the identification data results from appending a 16-bit suffix to the bit string representing "Alex Ample".

```

ld1 = 416C 6578 2041 6D70 6C65 0001   ld2 = 416C 6578 2041 6D70 6C65 0002
ld3 = 416C 6578 2041 6D70 6C65 0003   ld4 = 416C 6578 2041 6D70 6C65 0004
ld5 = 416C 6578 2041 6D70 6C65 0005   ld6 = 416C 6578 2041 6D70 6C65 0006
ld7 = 416C 6578 2041 6D70 6C65 0007   ld8 = 416C 6578 2041 6D70 6C65 0008

```

The format mechanism makes use of SHA-1, i.e. the third hash-function specified in ISO/IEC 10118-3<sup>[25]</sup>.

```
