**Aircraft Electrical Heating Systems**

**FOREWORD**

Changes in this revision are format/editorial only.

**INTRODUCTION**

The modern air transport utilizing main propulsion engines of the turbo-prop or turbo-jet types generally provides speed characteristics suitable for the generation of large quantities of electrical power. Proper speed characteristics may be inherent in the main engine design or may be provided through constant speed devices. The electrical load of modern aircraft is generally large, requiring sufficient generating capacity to meet all normal and emergency electrical demands. The use of electrical heating may be attractive since the generating capacity designed into the system to meet the cooling cycle and other non-continuous electrical loads becomes available for heating when cooling is not required.

## SAE AIR860 Revision A

### 1. SCOPE:

It is intended that the scope of this information report be limited to electrical heating of passenger, crew, and cargo compartments only.

No attempt has been made to develop the complete electrical circuitry associated with the electrical heating components; however, the electrical circuitry required for heating component operation, safety, and monitoring will be included as available.

Specific design information is given for various modern aircraft utilizing electrical heating. Each aircraft discussed will be identified by alphabetical letter designation and included in the appropriate appendix.

#### 1.1 Purpose:

This report is intended to furnish the aerospace industry with brief design information and data on cabin and cargo space electrical heating. The design information and data contained herein are applicable to modern aircraft utilizing main propulsion systems such as turbo-jet, turbo-fan, and turbo-prop.

### 2. REFERENCES:

There are no referenced publications specified herein.

### 3. GENERAL INFORMATION:

#### 3.1 General Design Considerations:

3.1.1 Electrical Power Availability: Electrical heating may be used to compliment other heating sources or used as a sole heating source, depending upon flight and ground operating mode, degree of system integration, control, and economic considerations of heat and power generation devices.

3.1.2 Ground Power Sources: Ground power sources capable of supplying sufficient electrical power are available, thus permitting electrical heating of the aircraft on the ground without requiring main engine operation.

3.1.3 Reliability and Flexibility: A high degree of reliability and flexibility may be attained in the use of electrical heating.

3.1.4 Weight: The weight penalty incurred by using electrical heating may be small compared to other heat generating sources provided generator capacity is available as a requirement of meeting other electrical loads.

3.1.5 Location: The use of electrical heating may be more suitable when compared to other methods when the area or location of the area to be heated presents unusual heating design problems.

3.1.6 Control of Heating Elements: Control of electrical heating elements is simple.

**SAE AIR860 Revision A**

- 3.1.7 Heating System Integration: Integration of electrical heating system with other heat sources can be accomplished. Proper integration and control can provide maximum passenger and crew comfort by the elimination of cold surfaces adjacent to passengers and the elimination of circulating air at uncomfortable air temperature gradients.
- 3.1.8 Heat Transmission: Heat may be transferred between various heat sources and heat sinks by one of the following, or a combination of the following, processes: convection, radiation, and conduction. In an aircraft cabin, heat transfer may take place in the following ways:
- a. Convection between the boundary layer and cabin outer skin.
  - b. Convection between the cabin interior surface and cabin air.
  - c. Convection between cabin air and passengers or equipment.
  - d. Convection and radiation from internal heat sources, such as electrical and electronic equipment, internal surfaces, and passengers.
  - e. Conduction through structural members and cabin walls.
